- Seriousness of the diagnosis/onset of illness or injury (e.g., acute or chronic)
- Support systems available, including the family and health care professionals
- Cultural background
- Parents' reaction to illness and hospitalization

The type of experience may contribute to increased anxiety and fear if the child must be admitted to the hospital. If children have had previous experiences, how the experience unfolded and their response to it will determine many of their reactions to hospitalization. Older children may cling to their parents, kick, or create a scene because of their previous experience. One research study compared the psychological responses of children hospitalized in a pediatric intensive care unit with those hospitalized on a general unit. Results showed that children who were younger, more severely ill, and who endured more invasive procedures had significantly more medical fears, a lower sense of control over their health, and ongoing posttraumatic stress responses for 6 months after discharge (Zengerle-Levy, 2006).

Recent Stresses and Changes and Individual Coping Skills

The effects of hospitalization on children are influenced by the nature and severity of the health problem, the condition of the child, and the degree to which activities and routines differ from those of everyday life. A lack of sensory stimulation in the hospital environment produces listlessness, indifference, unhappiness, and even appetite changes. When the child's motor activity is restricted, anger and hyperactivity may result. Play, recreation, and educational opportunities can provide an outlet to distract the child from the illness, provide pleasant experiences, and help the child understand his or her condition.

The child's ability to work through a situation will also affect his or her responses to illness and hospitalization. This ability depends on the age of the child, his or her perceptions of the event, previous encounters with health care personnel, and support from significant others. Table 32.1 lists various coping skills used by children and suggestions for promoting positive coping.

Parents' Response to Child's Hospitalization

Children take in their parents' anxiety and concern. Even whispers can set off children's imaginations. For example, preschoolers may invent elaborate stories to explain what is happening to them. Parents who do not tell children the truth or do not answer their questions confuse and frighten them and may weaken the child's trust in the parents. It is important for children to believe that someone is in control and that the person can be trusted. Some parents, however, have their own fears and insecurities. Thus, a child's reaction often is related to the parents' reaction to the illness and hospitalization.

The relationship between the family and the hospital staff may either add to or ease the child's stress. This relationship can contribute significantly to the quality of the environment. Hospital personnel must assume responsibility for the care of hospitalized children by maintaining good partnerships with families.

Remember Jake, the 8-year-old with a suspected brain tumor? What responses to hospitalization might you see in him and his family?

The Hospitalized Child's Family

Whether planned or unplanned, hospitalization increases the family's stress and anxiety level. The illness or serious injury of one family member affects all members of the family because the process disrupts the family's usual routines and may alter family roles. Parents and siblings have their own reactions to this experience.

Reactions of Parents

Watching a child in pain is difficult, especially when the parent is assisting with the procedure by holding the child. The parent may feel guilty for not seeking care sooner. Parents may also exhibit other feelings such as denial, anger, depression, and confusion. Parents may deny that the child is ill. They may express anger, especially directed at the nursing staff, another family member, or a higher power because of their loss of control in caring for the child. Depression may occur because of exhaustion and the psychological and physical requirements of spending long hours in a hospital caring for a child. Confusion may develop because of dealing with an unfamiliar environment or the loss of a parental role. Finally, the parents'

TABLE 32.1 CHILDREN AND COPING

Behavior/Methods for Coping	Suggestions to Promote Coping
Ignore or negate the problem	Breathing techniques such as blowing bubbles, pinwheels, or party noise-makers
Stoicism, passive acceptance	Distraction with books or games
Acting out—yelling, kicking, screaming, crying	Imagery with tapes or scenarios
Anger, withdrawal, rejection	Music
Intellectualizing	Teaching before events or procedures

marriage may be strained because of dual roles, long separation, and increased stress.

A recent study indicates that parents have experiences in four categories: facing boundaries, attempting to understand, coping with uncertainty, and seeking reassurance from caregivers (Stratton, 2004). First, parents feel helpless when they play a passive role in their child's care, such as when a medical procedure is required that hurts the child. Then parents attempt to understand by becoming informed and understanding the procedures. Next, they deal with the fear of uncertainty and attempt to promote a sense of comfort by interacting with the hospital staff. Finally, they seek reassurance from the caregivers.

Reactions of Siblings

Siblings of children who are hospitalized may experience jealousy, insecurity, resentment, confusion, and anxiety. They may have difficulty understanding why their sibling is ill or getting all the attention, leaving little for them. They may wonder if their sibling is going to die or ever return home. They may worry that their sibling's illness is going to happen to them. Certain age groups, such as preschoolers, may feel that they caused the illness. Their magical and egocentric thinking, combined with little information, contributes to their fears that they may have caused the illness or injury by their thoughts, wishes, or behaviors (Winch, 2001). If the family roles or routines change significantly, the siblings may feel insecure or anxious. They may develop changes in behavior or in school performance.

▶ *Take* NOTE!

Research supports the need to provide support and information to the siblings to decrease their stress, anxiety, and confusion.

Factors Influencing Family Reactions

The parenting style and the family–child relationship can influence the hospital experience as well as the family members' coping skills. Cultural, ethnic, and religious variations, values, and practices related to illness, general response to stress, and attitudes about the care of a sick child have a significant influence on the family's response. For example, religious beliefs can raise problems or can be a source of strength to the family and child. Families already in crisis or without support systems have a more difficult time dealing with the added stress of hospitalization. Chapter 2 gives further explanations of some of these influences on children and their families.

Jake's parents are very upset that he has to be hospitalized. His mother says to you, "I'm worried how Jake is going to react to all of this. What can we do to help him?" How would you address his mother's concerns?

The Nurse's Role in Caring for the Hospitalized Child

In most instances, the nurse is the primary person involved in the care of a hospitalized child. The nurse is probably the first one to see the child and family and will spend more time with them than other health care providers. Nurses are part of a medical community that makes decisions in the child's best interest, but the nurse needs to bear in mind the child's rights and must try to minimize the child's distress so that the hospital stay will be as pleasant an experience as possible. When establishing strategies to care for children in the hospital, nurses should examine the general effects of hospitalization on children in each developmental stage and should strive to understand the factors affecting hospitalization as well as the reactions of the child and family. Nursing Care Plan 32.1 summarizes the nursing care associated with a hospitalized child.

The initial contact with children and their families establishes the foundation for a trusting relationship. Each institution has its own criteria for admission and transfer of pediatric clients, formulated in light of its mission, abilities, and limitations. Use favorite toys and common television shows to establish rapport. Allow the child to participate in the conversation without the pressure of having to comply with requests or undergo any procedures. A trusting relationship can be built by using appropriate language, games, and play such as singing a song during a procedure, preparing the child adequately for procedures, and providing explanations and encouragement. Get down to the child's level and play on his or her terms.

The next two phases involve making judgments and providing feedback. Decisions must be made that will affect the trust the child has developed. For example, it is imperative to decide how much control the child will have during treatment, how much information to share with the child about upcoming events, and whether parents should participate. Reinforce the child's use of coping strategies that lead to healthy outcomes by providing options whenever it is safe to do so. Finally, the comfort and reassurance phase uses techniques such as praising the child and providing opportunities to cuddle with a favorite toy.

Preparing Children and Families for Hospitalization

When preparing children for hospitalization, be aware of the situations that may create distress in a child and try

(text continues on page 989)

Nursing Care Plan 32.1

OVERVIEW FOR THE HOSPITALIZED CHILD AND FAMILY

NURSING DIAGNOSIS: Anxiety related to hospital situation, fear of injury or bodily mutilation, separation from family or friends, changes in routine, painful procedures and treatments, and unfamiliar events and surroundings as evidenced by crying, fussing, withdrawal, or resistance

Outcome Identification and Evaluation

Child and family will exhibit a decrease in anxiety level as evidenced by positive coping strategies, verbalization or playing out of feelings, appropriate behaviors, positive interactions with staff, child and parent cooperation and participation, and absence of signs and symptoms of increasing anxiety and fear.

Interventions: Minimizing Anxiety

- Orient child and family to the unit and the child's room *to familiarize them with the facility.*
- Assess for signs and symptoms of anxiety and fear *to establish a baseline and assess effectiveness of interventions.*
- Place the child in a room with another child of a similar age, developmental level, and condition severity *to promote sharing.*
- Provide atraumatic care *to minimize exposure to distress, which would increase anxiety.*
- Explain all events, treatments, procedures, and activities to the parents and child (at a level the child can understand) in a calm, relaxed manner *to help the child prepare for what is to come and decrease fear of the unknown. A calm, relaxed manner helps to establish rapport and instill trust.*
- Encourage parents to room-in if possible *to provide the child with support;* if parents cannot stay, encourage them to call *to reduce child's fear of being alone.*
- Urge parents to inform the child when they will be leaving and when they are expected to return *to help child cope with their absence and promote trust.*
- Assess child's usual routine at home and attempt to incorporate aspects of usual routine into hospital routine *to ease the transition to the hospital and promote the child's participation in routine.*
- Offer comfort measures such as holding, stroking, and rocking *to relieve distress.*
- Encourage the child to play (unstructured and therapeutic play as necessary) *to allow for expression of feelings and fears and promote energy expenditure.*
- Suggest that parents bring in a special toy or object from home *to promote feelings of security.*
- Provide positive reinforcement for participation in care activities *to foster self-esteem.*
- Assess for regression behaviors and inform parents that such behaviors are common *to alleviate their concerns about this behavior.*
- Provide consistency with care measures *to facilitate trust and acceptance.*

NURSING DIAGNOSIS: Risk for powerlessness related to lack of control over procedures, treatments, and care, and changes in usual routine

Outcome Identification and Evaluation

Child and family will demonstrate an increase in control over the situation as evidenced by participation in care activities, identification of needs and choices, and incorporation of appropriate aspects of child's usual routine with that of the hospital.

Interventions: Promoting Control

- Encourage child and parents to identify areas of concern *to help determine priority needs.*
- Encourage parent and child to participate in care activities *to promote feelings of control.*
- Incorporate aspects of child's routine at home and use terms similar to those used at home *to foster a sense of normalcy.*
- Offer child choices as much as possible, such as options for foods, drinks, hygiene, activities, or clothing (if appropriate) to *promote feelings of individuality and control.*
- Allow child opportunities for being out of bed or room within limitations as appropriate *to foster independence.*
- Work with child, as age and development allow, and family to set up a schedule to *promote structure and routine.*

Nursing Care Plan 32.1 (continued)

NURSING DIAGNOSIS: Deficient diversional activity related to confinement in bed or health care facility, limited mobility, activity restrictions, or equipment as evidenced by verbalization of boredom, lack of participation in play, reading, or schoolwork

Outcome Identification and Evaluation

Child will participate in diversional activities as evidenced by engagement in unstructured and therapeutic play that is developmentally appropriate and interaction with family, staff, and other children.

Interventions: Promoting Adequate Diversional Activities

- Question child and family about favorite types of activities *to establish a baseline for developing appropriate choices during hospitalization.*
- Assist with planning activities within the limits of the child's condition *to maintain muscle tone and strength without overexerting the child.*
- Spend time with the child *to provide stimulation and foster trust.*
- Enlist the aid of a child life specialist *to provide suggestions for appropriate activities.*
- Encourage interaction with other children *to promote sharing and avoid loneliness.*
- Provide developmentally appropriate opportunities for unstructured and therapeutic play *to facilitate expression of feelings.*
- Encourage short trips to the playroom or activity room *to provide a change of scenery and sensory stimulation.*
- Integrate play activities with nursing care *to achieve therapeutic effect.*

NURSING DIAGNOSIS: Interrupted family processes related to separation from child due to hospitalization, increased demands of caring for an ill child, changes in role function, and effect of hospitalization on other family members such as siblings, as evidenced by parental verbalization of issues, parental presence in hospital, or child's hospitalization requiring parent to miss work

Outcome Identification and Evaluation

Family will demonstrate positive coping strategies as evidenced by visiting frequently and staying with the child as necessary, sharing of family responsibilities, obtaining assistance for relief or respite, and visiting by other members of the child's family and friends.

Interventions: Maximizing Family Functioning

- Encourage parents and family members to verbalize concerns about child's illness, diagnosis, and prognosis *to promote family-centered care and identify areas where intervention may be needed.*
- Explain therapies, procedures, child's behaviors, and plan of care to parents to *promote understanding of the child's status and plan of care, which helps to decrease anxiety.*
- Encourage parental involvement in care *to promote feelings of the parents being needed and valued, providing them with a sense of control over their child's health.*
- Identify support system for family and child *to identify resources available for coping.*
- Educate family and child on additional resources available *to promote a wider base of support to deal with the situation.*
- Suggest ways that parents can divide time between child and other siblings *to prevent feelings of guilt.*
- Provide support and positive reinforcement *to promote family coping and foster family strength.*
- Encourage frequent visits by family members, including siblings as appropriate, *to promote ongoing family functioning.*
- Stress the need for adequate rest, sleep, exercise, and nutrition for family members *to promote family health and minimize stress of hospitalization on family.*
- Assist with referrals for resources and help from additional family members and friends as necessary *to allow for respite or relief of care responsibilities.*
- Encourage family to maintain usual routine as much as possible *to minimize the effects of hospitalization on family functioning.*

(continued)

Nursing Care Plan 32.1 (continued)

NURSING DIAGNOSIS: Self-care deficit related to immobility, activity restrictions, regression, or use of equipment, devices, or prescribed treatments as evidenced by inability to feed, bathe, or dress self or accomplish other activities of daily living

Outcome Identification and Evaluation

Child will participate in self-care within limitations of condition as evidenced by assisting with bathing and hygiene, feeding, toileting, and dressing and grooming.

Interventions: Promoting Self-Care

- Assess child's usual routine for self-care and self-care abilities *to provide a baseline for individualizing interventions.*
- Provide child-sized equipment and devices *to promote child's ability to complete the self-care task.*
- Encourage parents and child to do as much self-care as possible, within limitations of the child's condition and developmental level, *to promote feelings of independence and foster growth and development.*
- Offer praise and encouragement for activities performed *to foster self-esteem, confidence, and competence.*
- Ensure adequate rest periods *to minimize energy expenditure associated with self-care activities.*

NURSING DIAGNOSIS: Risk for delayed growth and development related to stressors associated with hospitalization, current condition or illness, separation from family, and sensory overload or sensory deprivation

Outcome Identification and Evaluation

Child will demonstrate developmentally appropriate milestones as evidenced by age-appropriate behaviors and activities.

Interventions: Promoting Growth and Development

- Assess child's developmental stage *to establish a baseline and determine appropriate strategies.*
- Use unstructured and therapeutic play and adaptive toys *to promote developmental functioning.*
- Provide stimulating environment when possible *to maximize potential for growth and development.*
- Praise accomplishments and emphasize child's abilities *to foster self-esteem and encourage feelings of confidence and competence.*
- Include parents in techniques to foster growth and development *to promote feelings of control in their child's care.*

NURSING DIAGNOSIS: Deficient knowledge related to hospitalization, surgery, treatments, procedures, required care, and follow-up as evidenced by questioning and verbalization, lack of prior exposure

Outcome Identification and Evaluation

Child and family will demonstrate understanding of all aspects of child's current situation as evidenced by identification of child's and family's needs, verbal statements of understanding and/or need for additional information, return demonstration of procedures and treatments, and verbalization of instructions for follow-up and continued care.

Interventions: Providing Child and Family Teaching

- Assess child's and family's willingness to learn *to ensure effective teaching.*
- Provide family with time to adjust to diagnosis *to facilitate their ability to learn and participate in the child's care.*
- Repeat information *to promote multiple opportunities for child and family to learn.*
- Teach in short sessions *to prevent overloading the child and parents with information.*
- Gear teaching to appropriate level of understanding for the child and the family (depends on age of child, physical condition, memory) *to promote learning.*
- Provide reinforcement and rewards *to facilitate the teaching/learning process.*
- Use multiple modes of learning, such as written information, verbal instruction, demonstrations, and media, when possible *to facilitate learning and retention of information.*
- Provide the child and family with written step-by-step instructions for procedures or care *to provide a reference if needed at a later date.*
- Have child and family provide return demonstrations of care procedures *to ensure effectiveness of teaching.*
- Arrange for trial home care during hospitalization and after discharge as appropriate *to ensure understanding and provide opportunities for additional teaching and learning.*

to minimize or eliminate them. Even the most minor situations may be frightening to young children. New experiences, unfamiliar sights and sounds, disruption of sleep patterns, and pain associated with procedures and treatments are major causes of stress for the hospitalized child and family (Zengerle-Levy, 2006). Table 32.2 presents some hospital activities that may seem scary or stressful to a child and gives suggestions for preparing the child and family. Thoughtful preparation for these situations may relieve the stress. Educate children about what to expect so they can cope with their imagination and distinguish reality from fantasy. Describe the intervention and the sequence of steps that will occur, and include sensory information such as how the child will feel.

Good preparation can reduce the child's fears and increase his or her ability to cope with the hospital experience. Preparation should include exploring the child's perceptions, reviewing previous experiences, and identifying coping strategies. Useful techniques include the following:

- Perform nursing care on stuffed animals or dolls and allow the child to do the same.

TABLE 32.2 STRATEGIES TO REDUCE FEAR OF COMMON HOSPITALIZATION SITUATIONS

Situation	Strategies to Reduce Fear
Procedure involving intrusion into the body or use of equipment or technology	Describe the procedure and equipment in terms the child can understand. Review the steps of the procedure or steps involved with the use of the equipment. Explain what the child's role will be and what is or isn't allowed. If appropriate, have the child rehearse with the equipment or role play.
Darkness, such as with radiologic examinations or at night	Keep a light on in the examination area. Use a night light in the child's room. If possible, allow the child to hold the caregiver's or nurse's hand or a favorite toy.
Transport to other areas of the hospital	Allow caregiver to accompany child if possible. Inform the child of where he or she is going, about how long he or she will be there, and approximately when he or she will return. Introduce the child to the person who will be transporting the child.
Numerous personnel in and out of child's room	Identify all staff members working with the child (each shift and each day). Place a small board in the child's room with the name of the nurse caring for the child that shift or day. Inform the child how long the nurse will be caring for the child (adapt this information according to the child's cognitive level; for example, instead of saying that you'll be there for 8 hours, say, "I'll be your nurse until just before dinnertime" or "I'll be your nurse until you go for your test"). Say good-bye to the child when leaving for the day; tell the child about his or her new nurse; inform the child of when you will return.

- Avoid the use of medical terms.
- Allow the child to handle some equipment.
- Teach the child the steps of the procedure or inform him or her exactly what will happen during the hospital stay.
- Show the child the room where he or she will be staying.
- Introduce the child to the health care personnel with whom he or she will come in contact.
- Explain the sounds the child may hear.
- Let the child sample the food that will be served.

All techniques used to prepare the child for hospitalization should emphasize the philosophy of atraumatic care. "The main goal of preparation is for the child to participate in a dialogue and a demonstration of the coming procedure so he or she can better understand the situation" (Mansson & Dykes, 2004). Adapt all information to the cognitive and developmental level of the child. Identify what role the child will play in the situation: it is always helpful for children to have something to do, since it shows them that they are included. A rehearsal of what will occur in the hospital allows the child to become comfortable with the situation. If time permits, provide pamphlets that describe the procedure and suggest preparation activities for the child at home before admission.

The child and family may be able to take a tour of the hospital unit or the surgical facility. Videotapes or DVDs, photographs, and books on hospitalization and surgery can serve as resources for the family and child. Many institutions offer programs to familiarize children and families with the hospital experience. For example, one institution uses a "train ride" to help them understand what to expect (Herron, 2005). During the ride, opportunities are provided for role playing, and during stops along the way the child can see, touch, and feel the equipment that may be used (Fig. 32.2).

FIGURE 32.2 A child is being prepared for hospitalization by becoming familiar with some of the equipment that might be used.

The American Society of Anesthesiologists has prepared a coloring book entitled "My Trip to the Hospital." This book is designed to alleviate some of the fears that younger children may have related to the hospital experience. It describes the process from admission (whether it be to the hospital or ambulatory surgery center) through discharge and includes information about preoperative testing, anesthesia, and recovery. The book also includes information for parents. The book is available online at http://www.asahq.org/patientEducation/mytrip.htm.

Parents are instrumental in preparing children by reviewing the materials that are given, answering questions, and being truthful and supportive. Teaching Guidelines 32.1 provides suggestions for parents in preparing their child for hospitalization. Table 32.3 discusses strategies for preoperative teaching.

Admitting the Child to the Facility

Admitting the child to the facility involves preparing him or her for admission and introducing the child to the unit where he or she will be staying. Use the appropriate hospital forms. Chapter 2 gives general information about communicating with and teaching children and families.

In today's health care environment, the admission process occurs quickly, with little time for extensive preparation; this is why preparation before admission is so important. Of course, the urgency of the child's medical condition also may limit the amount of preparation that can be done in advance.

Types of Admissions and Nursing Care

The hospital units to which a child may be admitted include:

- General inpatient unit
- Emergency and urgent care department

TEACHING GUIDELINES 32.1

Preparing Your Child for Hospitalization

- Read stories about experiences with hospital or surgery.
- Talk about going to the hospital and what it will be like coming home.
- Be honest and encourage the child to ask questions.
- Visit the hospital and go through the preadmission tour if time permits.
- Provide support to the child via your presence, telephone calls, and special items brought from home.
- Encourage the child to draw pictures to express how he or she is feeling.
- Include siblings in the preparation.

TABLE 32.3 STRATEGIES FOR PREOPERATIVE TEACHING

Developmental Level	Implications for Teaching
Infants and toddlers	Encourage parents to use a soft tone of voice and stroking and secure, comfortable holding positions to promote calm. Remind parents to use positive facial expressions. Encourage the parent or caregiver to stay with the child as much as possible. Use terms that the child and parents can understand. For toddlers, provide information as close to the day of surgery as possible to prevent undue anxiety.
Preschoolers and school-age children	Provide factual explanations using terms the child and parents can understand. Incorporate pictures and other visual aids in explanation. Tailor the timing of education to meet the child's learning needs, allowing enough time for the child to ask questions. Some recommend that information be provided no more than 1 week beforehand for school-age children. (Justus et al., 2006).
Adolescents	Provide detailed explanations of the procedure at least 7 to 10 days beforehand. Answer questions honestly, ensuring privacy at all times. Remain available for questions or concerns arising before or after surgery.

- Pediatric intensive care unit
- Outpatient or special procedures unit
- Rehabilitation unit or hospital

Regardless of the site of care, nursing care must begin by establishing a trusting, caring relationship with the child and family. Smile, introduce yourself, and give your title. Let the child and family know what will happen and what is expected of them. Ask the family and child what names they prefer to be called by. Maintain eye contact at the appropriate level. With a younger child, start with the family first so the child can see that the family trusts you. Communicate with children at age-appropriate levels.

The next step, as the child's medical condition allows, involves an orientation to the hospital unit. Briefly explain policies and routines and the personnel who will be involved in the care of the child.

During the nursing interview that follows, obtain information about the child's history, routines, and reason for admission. Obtain baseline vital signs, height and weight, and perform a physical assessment. Each health care setting has its own policies and procedures for this. Recognize the needs of the family and child during this process. If some of this information already exists, do not ask for it again, except to confirm vital information such as allergies, medications taken at home, and history of the illness. Typically, the information is collected immediately if the child's condition is urgent; otherwise, the information is collected within 8 hours, except for the information that is required for safe care.

General Inpatient Unit Stays

Today, general inpatient unit stays for children are shorter and involve more acute conditions, resulting in little time for admission preparation. Many times the admission procedure and treatment actually occur simultaneously. Sometimes the stay is in a special 23-hour observation unit so the child is in the setting for less than 24 hours. General hospital stays may be in a pediatric hospital, a pediatric unit in a general hospital, or a general unit that occasion-

ally admits children. General units often lack child-oriented services, such as play areas, child-size equipment, and staff familiar with caring for children.

▶ *Take* NOTE!

When a child is admitted to a general unit, take extra time to orient and explain the routines and procedures to the child and family. Emphasize that the parents can stay with the child (if institutional policy permits). If possible, place the child in a room close to the nurses' station and order food appropriate for the child's age and developmental level.

Emergency and Urgent Care Departments

The number-one reason for illness and hospitalization in children is injuries from accidents. Many times a family's first experience with the acute care setting is the urgent care or emergency department. Due to the situation, the child and family may experience increased anxiety, and it may become overwhelming as uncertainties develop and critical decisions must be made. The family may be frightened, insecure, and in a state of shock.

Procedures and tests are performed quickly, with minimal time for preparation. The family is often ill prepared for the visit, having little money or clothing with them. Siblings may be present if the parents did not have time to get a sitter.

Due to the fast pace of the emergency department, the family may be hesitant to ask questions, so keep the family and child well informed. Allow the family to stay with the child, provide support, and allow the family, and when appropriate the child, to participate in decisions.

Families may have a strong fear of the unknown and may be terrified that the child will die or be permanently disabled. Help the family to identify their concerns and their support systems. Prepare them for what they will experience. Provide comfort such as holding, touching, talking softly, and other appropriate interventions according to age and developmental level.

Pediatric Intensive Care Units

The pediatric intensive care unit (PICU) specializes in caring for children in crisis. The same principles and concepts of general care of children apply to this setting, but everything is intensified. Families will be faced with an unfamiliar, high-tech environment and a large number of staff.

Families must deal with the critical situation that brought them to the PICU. The child will likely experience pain, unusual noises, and increased stimulation and will probably undergo uncomfortable procedures. Parents may face the possibility of losing their child. Sometimes the child cannot talk, eat, or display other appropriate developmental behaviors. **Sensory overload** (increased stimulation) or **sensory deprivation** (lack of stimulation) can affect both child and family.

Welcome families (if institutional policy permits) and encourage them to stay with the child and participate in care. Explain everything to the parents and, when appropriate, to the child. Frequently touch the child and encourage the parents to comfort him or her. Listen for clues about what the child and family need during the PICU stay.

Outpatient or Special Procedure Units

Outpatient or special procedure units are used to keep hospital stays short and decrease the cost of hospitalization. These units may be a part of a general hospital or a freestanding facility. Typically, the child and family arrive in the morning; the child has the procedure, test, or surgery and then goes home later that same day. Examples of procedures performed in outpatient settings include tympanostomy tube placement, hernia repair, tonsillectomy, cystoscopy, bronchoscopy, and chemotherapy.

This setting minimizes separation of the child from the family. In addition, there is minimal disruption of the family pattern, a decreased risk of infection, and decreased cost. However, these units do not have the equipment for overnight stays, so if complications develop, the child will need to be transported to another facility or another area of the hospital.

Rehabilitation Units

The rehabilitation unit provides care for children beyond the initial period of illness or injury. The care involves an interdisciplinary approach that assists the child to reach his or her potential and achieve developmental skills. For example, rehabilitation units help children regain abilities lost due to neurologic injuries or serious burns. The facilities often resemble a home environment, with special services to help children to relearn activities of daily living and to help them deal with the physical or mental challenges associated with the original illness or injury. Typically, families are encouraged to participate and are given support for their child's eventual return home. There is a balance of nurturing and firm discipline while the child reclaims independence.

Isolation Rooms

Isolation rooms are used for situations involving the risk for infection. When a child is admitted with an infectious disease, or to rule out an infectious disease, or if the child has impaired immune function, isolation will be instituted. Children in this setting may experience sensory deprivation due to the limited contact with others and the use of personal protective equipment such as gloves, masks, and gowns.

Encourage the family to visit often, and help them to understand the reason for the isolation and any special procedures that are required. Introduce yourself before entering the room and allow the child to view your face before applying a mask. Continue to have contact with the child and hold or touch the child often, especially if the parents are not present.

Addressing the Effects of Hospitalization Developmentally

When addressing the fears, separation anxiety, and loss of control that occur in hospitalized children, the nurse should consider the child's age and cognitive or developmental level. Interventions are then based on how the child experiences these stressors at that age or developmental level. The content, timing, setting, and method of preparation are also based on the child's age and cognitive or developmental level. General guidelines for addressing fear and anxiety, separation anxiety, and loss of control are provided in Box 32.2.

Newborns and Infants

Assess the development or lack of development that is occurring in the infant, and assess the baby's attachment to the parents or primary caregivers. The infant's facial expression is the most consistent indicator of pain or bodily injury. To decrease fear and minimize separation anxiety, avoid separation from the primary caregiver if possible; this will also promote healthy attachment. If the parent or primary caregiver cannot stay with the infant, arrange for volunteers to provide consistent comfort to the baby. Maintaining the infant's home routine related to sleep and feeding helps decrease feelings of loss of control. Weigh the infant daily, at the same time, on the same scale. Monitor intake and output closely. Be alert to signs of discomfort other than crying, such as a furrowed brow or tense body posture. Additional nursing goals related to promoting growth and development of the infant are presented in Table 32.4.

Toddlers

Key nursing concerns when caring for toddlers are separation anxiety, growth and development, and autonomy. Establishing a trusting relationship with the toddler through nonthreatening play may decrease the amount of fear the toddler feels. Be alert to subtle, nonverbal indicators of grief or discontent.

Encourage the parent or primary caregiver to stay with the toddler in the hospital to decrease separation anxiety. Maintaining the home routine related to meals and sleep or a nap provides structure and may help decrease the toddler's feelings of loss of control. If indicated, weigh the toddler daily. Closely monitor intake and output. Refer to Table 32.4 for additional nursing considerations related to promoting growth and development in the hospitalized toddler.

BOX 32.2 Guidelines to Address the General Effects of Hospitalization

Minimizing Fear and Anxiety

- Consider the effects of magical thinking.
- Explain everything to children and their families before it occurs (see Chapter 35).
- Use age-appropriate communication techniques. Include the family in this process so they can help the child cope with fears.
- Allow time for children to play out their fears and concerns.
- Talk to the child and parents using a soft, comforting tone of voice, with the parent or caregiver holding the child.

Addressing/Minimizing Separation Anxiety

- Know the stages of separation anxiety and be able to recognize them.
- Remember that behaviors demonstrated during the first stage do not indicate that the child is "bad."
- Encourage the family to stay with the child.
- Help the child cope, and intervene before the behaviors of detachment occur.
- Try guided imagery, using the child's imagination and enjoyment of play, to help the child relax (Bricher, 2000).

Addressing Loss of Control

- Minimize physical restrictions, altered routines and rituals, and dependency issues, because they produce loss of control.
- Allow as much independence as possible within the constraints of the diagnosis.
- Recognize the child's inherent powerlessness in the hospital setting and explore strategies that give children an opportunity to participate in their own health care decisions (Bricher, 2000).

Preschoolers

Nursing care for hospitalized preschoolers focuses on their special needs, fears, and fantasies. When working with preschoolers, remember that they use magical thinking and fantasy. Be honest and specific, providing information just prior to the intervention to allay the child's fears. As with toddlers, encouraging parental involvement may decrease the amount of separation anxiety the preschooler experiences while in the hospital. Allowing the preschooler to make simple decisions such as which color bandage to use or whether to take medicine from a cup or syringe helps the child to feel some sense of control. Table 32.4 gives specific nursing considerations related to promoting growth and development for the preschooler in the hospital.

TABLE 32.4 NURSING CONSIDERATIONS FOR PROVIDING SAFE, DEVELOPMENTALLY APPROPRIATE CARE

	Ensuring Safety	Promoting Healthy Growth and Development
Infants	• Maintain close supervision of the infant. • Keep one hand on the infant when crib sides are down. • Keep crib rails up all the way when the infant is in the crib. • Avoid leaving small objects that are harmful or that can be swallowed in the crib. • Provide safe and appropriate toys for the infant. • Place infants in rooms close to the nurses' station. • Encourage a family member to stay with the infant at all times.	• Use the *en face* position when holding newborns. • Smile and talk to the infant during bathing, feeding, and other interactions. • Minimize the number of painful or uncomfortable procedures. • Provide comfort during and after procedures by holding or talking, using soothing tones and movements. • When handling the infant, use smooth, continuous movements. • Use gentle stroking and holding, which may reduce stress. • Serve as a role model for first-time parents. • Encourage the family to maintain home routines while in hospital, planning nursing care around the usual feeding and sleep times. • Use the pacifier between feedings to satisfy nonnutritive sucking needs.
Toddlers	• Keep crib side rails up with overhead crib protection intact when the toddler is in the crib. • Never leave a toddler alone in the room unless secured in the crib. • Use a bed only for the older toddler who has an adult present in the room at all times. • Avoid leaving small objects than can be swallowed or are harmful in the crib or bed. • Place crib out of reach of cords, equipment, and electrical outlets. • Provide safe and appropriate toys for the toddler. • Always have someone with the toddler when ambulating.	• Encourage the parent to stay with the toddler to decrease separation anxiety. • To promote autonomy, allow the toddler to make appropriate choices, such as which juice to take the medicine with. • Encourage active play in the playroom or with push/pull toys in the hallway (accompanied by an adult). • Expect and plan for regression in areas of toilet training, eating, and other behaviors. • Expect increased temper tantrums in general and intense reactions to intrusive procedures. • Maintain home routine while in hospital, planning nursing care around the usual feeding and sleep times. • Give simple directions with choices appropriate to the hospital situation. • Place toddlers in rooms close to the nurses' station. • Provide close supervision while encouraging independence.
Preschoolers	• Keep bed in low position with the side rails up when the preschooler is in the bed. • Instruct the child to call the nurse or caregiver for help getting out of bed. • Keep harmful objects out of reach of the child.	• Encourage parents to stay with the preschooler in the room as well as other areas of the hospital. • Encourage the preschooler to be involved in care by providing choices and opportunities for the child to help. • Use play as an opportunity to work through the preschooler's fears. • Explain activities in simple, concrete terms, being cautious with the words you use because of the preschooler's fantasies and magical thinking. • Expect reactions to pain and bodily injury to be verbally aggressive and specific. • Try to maintain home routines while the child is in the hospital, working them into the plan of care when possible.

	Ensuring Safety	Promoting Healthy Growth and Development
School-age children	• Keep the bed in the low position with the side rails up while the child is in the bed, explaining that this is a hospital rule, not a punishment.	• Provide opportunities for the child to be involved in care. • Allow children to select their meals, assist with treatments, and keep their rooms neat. • Allow visits with other children if condition allows. • Encourage parents to tell the child when they will return. • Plan care around the child's usual home routines (meals, sleep). • Encourage the child to do schoolwork.
Adolescents	• Be aware of the adolescent's whereabouts. The teen may not wish to stay in the room but may become confused about where the room or unit is located in the hospital.	• Allow teens to interact with others. • Alter hospital routines as possible to allow the teen to sleep in or stay up later at night. • Provide others close to their age as roommates. • Encourage visits from friends. • Provide emotional support for feelings of being alone or away from friends; be alert for regression, which may result in the teen becoming emotional. • Answer questions honestly and with appropriate information. • Give the teen a sense of control by allowing choices. • Be sensitive to concerns about being "different."

School-Age Children

Provide honest information using concrete, meaningful words to the school-age child to minimize fear of the unknown. School-age children are still very attached to their parents, so encouraging parental involvement or rooming-in decreases separation anxiety. Involve the child in making simple decisions and planning the schedule as appropriate to give him or her a sense of control. Nursing considerations when caring for hospitalized school-age children include ensuring safety and promoting growth and development (see Table 32.4).

Adolescents

The adolescent may or may not express fears. Educate the teen honestly: younger teens require more concrete explanations, while older teens can process more abstract concepts. Respect the teen's need for privacy. Encourage visits from the adolescent's friends to minimize anxiety related to separation. Prepare a mutually agreeable schedule with the teen, as appropriate, that includes the teen's preferences while incorporating the required nursing care. Collaborating with the adolescent will provide the teen with increased control. Refer to Table 32.4 for additional nursing considerations related to care of the adolescent in the hospital.

Think back to Jake, the 8-year-old from the beginning of the chapter. Discuss nursing care you could provide that will help minimize stressors.

Preparing the Child and Family for Surgery

If the child is to undergo a surgical procedure, whether in the hospital or an outpatient setting, special interventions are necessary. The parents should be allowed to stay with the child until surgery begins. Parents should also be allowed to be with the child when he or she wakes up in the post-anesthesia recovery area. Good preparation provides reassurance and comfort to the child and allows him or her to know what will happen and what is expected of him or her.

Preoperative Care

Preoperative care for the child who is to undergo surgery is similar to that for an adult. The major difference is that the preparation and teaching must be geared to the child's age and developmental level. Many facilities offer special programs to help prepare children and families for the surgical experience. Presurgical preparation programs allow children and their families to experience a "trial run" in a supportive environment to reduce anxiety, increase knowledge, and enhance coping skills (Justus et al., 2006). Books, including the one cited earlier by the American Society of Anesthesiologists, are helpful in preparing the child and family.

Child and family teaching is essential. Like any intervention, adapt the teaching to the child's developmental level. For example, when teaching a toddler or preschooler about breathing exercises, have the child blow a pinwheel or cotton balls across the table through a straw.

FIGURE 32.3 Using a stuffed animal to explain a surgical procedure to the child.

FIGURE 32.4 Safety is an essential aspect of pediatric nursing. A clear plastic cover over the crib prevents the older infant or toddler from climbing out and falling.

The child will enjoy the activity while also reaping the respiratory benefits of the activity.

In preparation for surgery, use items such as stuffed animals or dolls to help children understand what is going to happen to them (Fig. 32.3). Allow the child to role-play various experiences with dolls. Dolls designed to simulate surgical experiences have been developed. For example, Shadow Buddies (www.shadowbuddies.org) are custom-made dolls that have the same illness or surgery as the child; the doll may have an ostomy, scar, or catheter. The dolls were developed to help children cope with their illness or disease and send the message that it is okay to be different. These dolls also provide the child with a companion to talk to.

▶ ***Take*** NOTE!

The presence of parents during anesthesia induction reduces child and parent anxiety as well as the incidence of adverse effects (Romino et al., 2005).

Maintaining Safety During Hospitalization

Safety is a critical aspect of care of the child in the hospital. Due to their age and developmental level, children are vulnerable to harm. Ensure the child has an identification band in place at all times. Sometimes in implementing interventions an armband is removed, so make sure it is attached to another extremity. Monitor children closely to avoid accidents such as a child pushing the wrong knob, picking up a piece of equipment or supplies left in the bed or room, or climbing out of bed (Fig. 32.4). Table 32.4 provides nursing goals for ensuring safe, developmentally appropriate care for the hospitalized child.

Use of Restraints

When caring for children, some type of restriction may be necessary. The restriction, often referred to as a restraint, may be needed to ensure the child's safety, allow a therapeutic or diagnostic procedure to be done, immobilize a body part or limit movement, or prevent disruption of prescribed therapy. However, restraints can be overused and can cause harm. As a result, the Joint Commission on Accreditation of Healthcare Organizations (JCAHO, 2005) issued standards related to the use of restraints designed to safeguard clients' physical safety and psychological well-being.

According to these standards, hospitals are required to have a policy in place that specifies the following:

- Reason for the restraint
- Client assessment parameters identifying the need for the restraint
- Use of at least one alternative method for restriction before using a restraint
- Use of the least restrictive type of restraint for the purpose after the decision is made that a restraint is necessary
- Need for a written order by a licensed independent practitioner (LIP) within 1 hour of application of the restraint
- Need for evaluation by LIP within 1 hour of application of the restraint

In addition, the JCAHO standards also identify the need for specific staff training and frequent assessment and appropriate discontinuation of use.

▶ ***Take*** NOTE!

When deciding whether it is necessary to restrain a child, consider the child's age, developmental level, mental status, and threat to others and self.

EVIDENCE-BASED PRACTICE 32.1
Preventing Falls in the Hospitalized Child

Hospitals are increasingly emphasizing the importance of client safety. Due to developmental issues, children are at a high risk of falls. Pediatric and adult clients fall for different reasons. Can adult fall risk factor scales assist in predicting falls in children? What variables increase the risk of falling for the pediatric client?

● Study
A descriptive study was done to identify risk factors in hospitalized children based on two adult fall risk factor scales, the Morse Fall Scale and the Hendrich II Fall Risk Model. A retrospective chart audit was performed to identify 100 hospitalized children who had fallen. Each client who had fallen was matched according to chronological age and year of hospitalization with a child who had not fallen. Analysis was performed to describe sample demographics, length of stay, and environmental fall characteristics. Further analysis was done to determine statistically significant differences in children who fell and those who did not fall based on the risk factor scales.

▲ Findings
A statistically significant difference was found using the Morse Fall Scale between fallers and non-fallers for history of falls, impaired gait, and mental status. However, the tools used to assess fall risk in adults do not appear to be applicable to children, as several items defined on adult fall scales do not apply to children. The authors determined that a valid and reliable pediatric fall rating scale needs to be developed. The study also showed that having a caregiver in attendance did not provide adequate protection against falls. Visits to the bathroom and entry and exit from a bed were associated with increased fall risk.

■ Nursing Implications
Factors such as an unfamiliar environment, impaired gait, and disorientation contribute to falls in hospitalized children. Nurses should educate caregivers about the risk of falls, providing appropriate guidance for assisting their child when getting into and out of bed or using the bathroom. Orient the child to the environment, repeatedly if necessary. Continue close supervision and monitor disoriented children and those with an impaired gait very frequently.

Razmus, I., Wilson, D., Smith, R., & Newman, E. (2006). Falls in hospitalized children. *Pediatric Nursing, 32*(6), 568–572.

Restraints can promote physical distress in a child. Children also may view restraints as punishment. Before a restraint is used, other measures need to be tried. Explain why the child should not touch the intravenous site or should maintain a certain position so that he or she has a basic understanding of what is necessary. This may be all that is necessary for an older child.

Therapeutic hugging (a holding position that promotes close physical contact between the child and a parent or caregiver) may be used for certain procedures or treatments where the child must remain still. For example, the parent can hold the child in his or her lap snugly to prevent the child from moving during an injection or venipuncture. This technique may be used to position a child for intravenous access, injections, an otoscopic examination, or a lumbar puncture. When using this technique, make sure the parent understands his or her role and knows which body parts to hold still in a safe manner.

Alternatively, distraction or stimulation (such as with a toy) can help to gain the child's cooperation. One-to-one supervision and behavior modification techniques may be other alternatives to the use of restraints.

If it is determined that a restraint is needed, select the most appropriate, least restrictive type of restraint. For example, if the child has an intravenous catheter in the antecubital space that stops flowing when the child bends the arm, an elbow restraint or arm board, rather than a soft wrist restraint or four-point extremity restraint, would be appropriate. Table 32.5 lists the types of restraints and the major issues associated with the use of restraints in children.

▶ *Take* NOTE!

When selecting a restraint, the nurse must choose the least restrictive type and apply it for the shortest time necessary.

Before applying a restraint, explain the reason for the restraint to the child and the parents. Emphasize that the rationale is to maintain the child's safety; the restraint is not punishment. Having the child and parents state the reason for the restraint demonstrates their understanding.

A written order for the restraint and an evaluation of the child by a LIP must occur within 1 hour of applying the restraint. In addition, the nurse must do the following:

- Ensure that the restraint fits properly.
- Secure the restraints with ties to the bed or crib frame, not the side rails.

TABLE 32.5 TYPES OF RESTRAINTS AND ASSOCIATED SAFETY CONCERNS

Type of Restraint	Purpose	Safety Concerns
Soft limb restraint 	Wrist or ankle restraint to prevent range of motion of extremities	Check wrist or ankle for any sign of circulatory, integumentary, or neurologic compromise.
Elbow restraint	Prevents child from flexing and reaching face, head, IV and other tubes	Position the restraint so it does not rub against axilla. Check pulse, temperature, and capillary refill of the extremity.
Mummy restraint	Body restraint using a sheet folded in a square appropriate to size of infant or young child to secure the whole body of the child or every extremity except for one	Ensure that all extremities are secured within the sheet.

Type of Restraint	Purpose	Safety Concerns
Jacket (vest) restraint	Jacket worn by child with ties attached to the child's back and to side of bed. Used to keep children flat in bed, such as after surgery, or safe in chair.	Ensure the child can turn head to side and that the head of the bed is elevated. Place ties in back so child cannot manipulate them.
Crib top bubble restraint	Clear plastic cover over the bed to prevent older infant or young child from falling and climbing out of bed	Ensure that there are no tears or loose plastic.

- Use a clove-hitch type of knot to secure the restraints with ties (this allows for quick, easy access and release of the restraint).
- Check restraints 15 minutes following initial placement and then every hour for proper placement.
- Assess the temperature of the affected extremities, pulses, and capillary refill, initially after 15 minutes and then every hour after placement.
- Remove the restraint every 2 hours to allow for range of motion and repositioning, with documentation of this process and any findings.
- Encourage parent participation, providing continuous explanations about the reasons for the restraints and tentative time frame for use.
- Offer positive reinforcement to the child and parents.
- Review the criteria for removing the restraints; document removal and continued assessment.

Transport of the Child

Children may need to be transported to other units for diagnostic tests or surgery, to different areas in the same unit, such as the playroom or treatment room, or for discharge. When the child is transported to other areas, specific guidelines need to address safety issues, the age and developmental level of the child, the child's physical condition, and the destination. These factors need to be considered before transport so that the appropriate method can be used with the least amount of risk for the child. Various methods to transport children include carrying the infant and using strollers, wagons, or rolling beds (Fig. 32.5). If possible, the parents should accompany the child to offer support and comfort.

When carrying an infant, good support of the back and head is vital. Rails should be up on all beds and wagons. Use safety belts with strollers and wheelchairs.

▶ *Take* NOTE!

Never leave a child unattended during transport. Keep the child visible at all times during the transport.

Providing Basic Care for the Hospitalized Child

Basic care involves general hygiene measures, including bathing, hair care, oral care, and nutritional care. Young children are dependent on an adult for most, if not all, of their self-care needs. If parents are present, allow them to provide care for the child to decrease the child's stress. Older children may perform hygiene measures themselves but may need some assistance from the nurse.

General Hygiene Measures

General hygiene measures help to maintain healthy skin, hair, and teeth. Skin is a complex structure; its primary function is to protect the tissues that it encloses and to protect itself. Injury to the child's skin may occur when inserting and maintaining an intravenous line, removing a dressing, positioning a child in bed, changing a diaper, using and removing electrode patches, and maintaining restraints. Risk factors for problems include impaired mobility, protein malnutrition, edema, incontinence, sensory loss, anemia, and infection. A good time to assess the skin is during bath time.

Bathing

Bathing infants and children is a common daily hygiene measure in the health care environment. Although the parents or primary caregiver often does this in today's family-centered environment, the nurse is still responsible for ensuring that bathing is done safely and hygienically. Adhere to safety principles to prevent falls, burns, and aspiration of water. Never leave a child alone in a bathtub. Use a gentle, pH-balanced soap with moisturizer if there is a need to rehydrate the skin. Note any condition that might require special considerations or further assessment, such as paralysis, loss of sensation, surgical incisions, skin traction/cast, external lines (intravenous lines, urinary catheters, or feeding tubes), or other alterations in skin integrity. Pay close attention to the ears, between skinfolds, the neck, the back, and the genital area for alterations in skin integrity. Table 32.6 highlights specific developmental considerations for bathing.

Before bathing and performing other hygiene measures, assess the family's preferences and home practices for the child, such as time of day, rituals, special equipment, and allergies to products. This is a good time to assess the amount of assistance that might be required by the parents and to address learning needs related to hygiene. Follow general guidelines in bathing any client with regard to equipment, room temperature, privacy, and use of products such as deodorant and lotion.

Hair Care

Lying in bed can make the hair matted and tangled. Avoid pulling on the child's hair when combing or brushing it. If necessary, use commercial detangling solutions to ease combing.

If the hair requires washing, this is often done during the daily bath for infants. Typically, shampooing once or twice a week is sufficient for younger children. Adolescents may need more frequent shampooing due to the increase in sebaceous gland secretion. The frequency of shampooing also varies based on the child's condition; for example, if the child has experienced diaphoresis, more frequent shampooing may be indicated.

Shampooing may be done at the bedside with specially adapted equipment, at a readily accessible sink while the

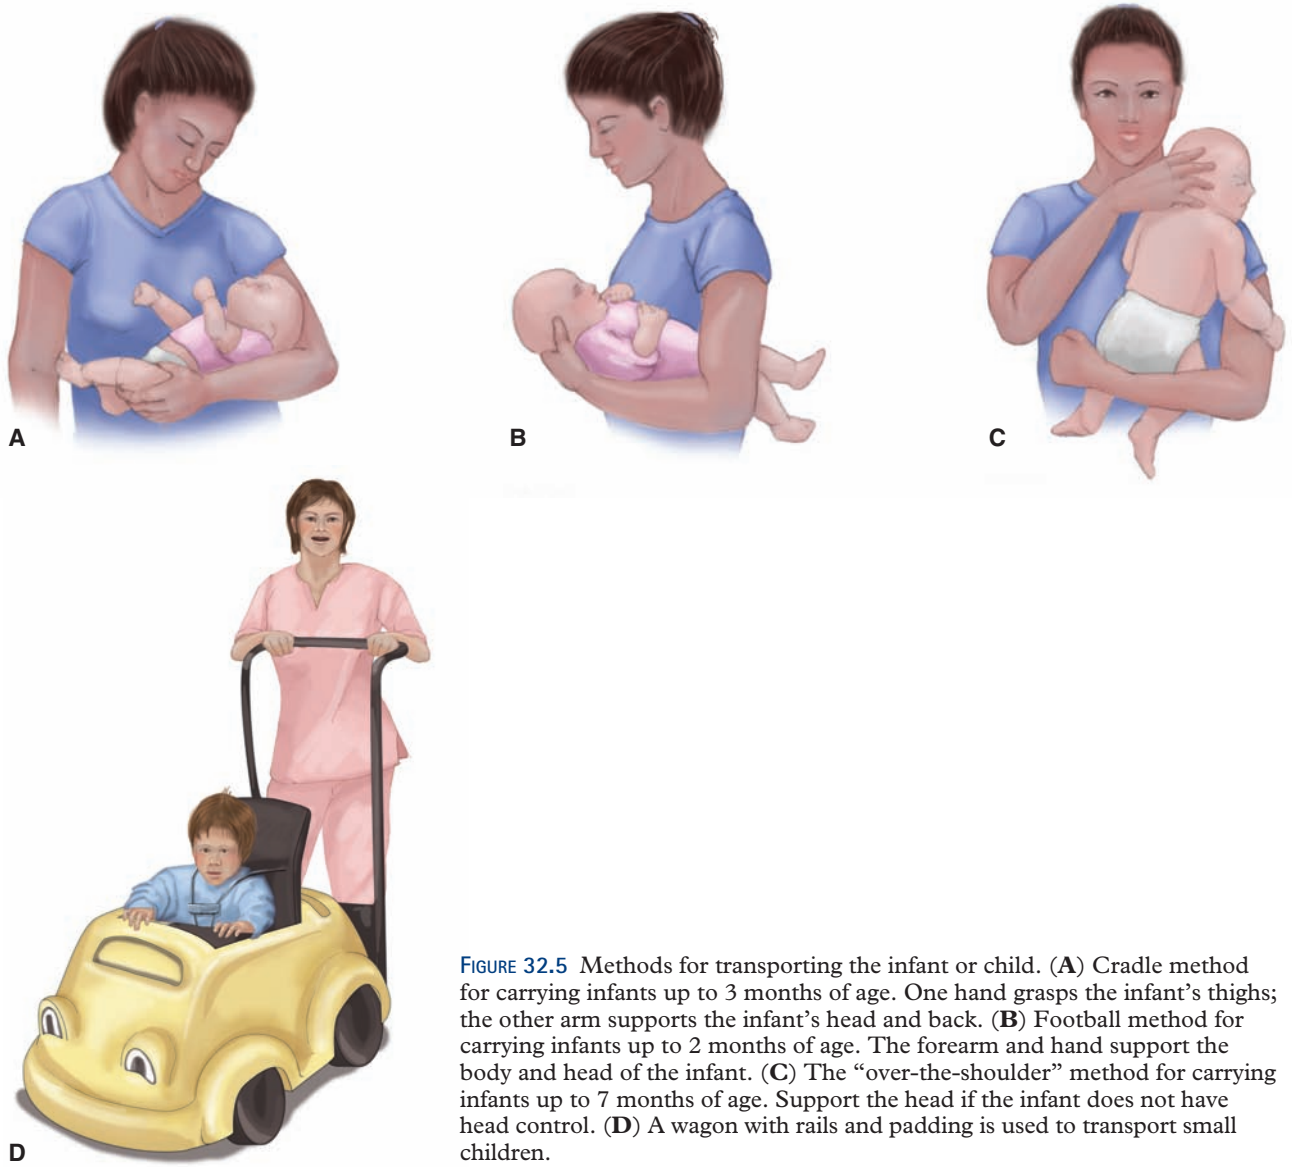

FIGURE 32.5 Methods for transporting the infant or child. (**A**) Cradle method for carrying infants up to 3 months of age. One hand grasps the infant's thighs; the other arm supports the infant's head and back. (**B**) Football method for carrying infants up to 2 months of age. The forearm and hand support the body and head of the infant. (**C**) The "over-the-shoulder" method for carrying infants up to 7 months of age. Support the head if the infant does not have head control. (**D**) A wagon with rails and padding is used to transport small children.

child is sitting in a chair or lying on a stretcher, or in a tub or shower. Commercial no-rinse shampoos may be available for use. With these products, the shampoo is applied to the hair and then brushed or combed out.

If the child uses a tub or shower for hair care, monitor the child's safety throughout to ensure that the child does not slip and fall due to the slippery surface or is burned because of improper water temperature.

The child's ethnicity may require special measures for hair care. For example, a child of African-American descent may use a broad-toothed comb for hair care. Ask the child's parents to bring one from home if one is not available. Also ask the child and parents about any products used on the hair to make it easier to handle; the parents can bring some from home. Encourage the parents to help with braiding or plaiting of the hair if desired.

▶ ***Take*** NOTE!

The hair of African-Americans typically is easier to comb when wet, so if possible comb the child's hair soon after shampooing.

Oral Hygiene

Oral hygiene is an important part of basic care. Wipe the infant's gums with a wet cloth after each feeding. Assist children in brushing and flossing their teeth after each feeding or meal and before bedtime. The child who is immunosuppressed needs special attention to oral hygiene, such as using soft toothbrushes and moistened gauze sponges to prevent bleeding and careful inspection of the oral cavity for areas of breakdown.

TABLE 32.6 DEVELOPMENTAL CONSIDERATIONS FOR BATHING

Age of Child	Special Considerations
Infants	Use a sponge bath or tub bath to bathe young infants who cannot sit unaided. Support the infant's body at all times. Ensure appropriate water temperature. Avoid use of talcum powder.
Toddlers	Bathe older infants and toddlers at the bedside or in a regular bathtub, depending on their health condition.
School-age children and adolescents	Older children may prefer a shower if available and acceptable for their health condition. Assess whether a shower would be safe. Provide privacy.

Nutritional Care

Adequate nutrition is necessary for growth and development and tissue repair, so it is an essential component of care for the ill or hospitalized child.

Frequently, the ill or hospitalized child experiences a loss of appetite, which can affect the child's nutritional status. This may be compounded by other problems such as nausea and vomiting and NPO restrictions for testing or surgery.

▶ ***Take*** *NOTE!*

Never attempt to force a child to eat. This can exacerbate nausea and vomiting and can lead to an aversion to food that extends past the hospital stay (Hockenberry, 2005).

If possible, schedule procedures or treatments away from mealtimes. In younger children, refusing to eat may be related to the child's feeling of separation; in others, refusing to eat may reflect the child's attempt to control the situation. Encourage parents to use gentle persuasion instead of force to assist with intake. They should give the child choices about what to eat; this reinforces the child's sense of control. Remind parents that the child's appetite will probably improve as his or her condition improves. Teaching Guidelines 32.2 provides tips for promoting nutrition in the hospitalized child. Although geared to parents, nurses also can incorporate these guidelines into the child's plan of care.

TEACHING GUIDELINES 32.2

Promoting Nutrition for Your Hospitalized Child

- Check with the nurse about any restrictions related to your child's diet. Find out if intake and output are being monitored.
- Encourage your child to eat his or her favorite foods.
- Assist your child with eating or drinking as necessary; be present at mealtimes to promote socialization.
- Frequently offer small cups of fluid and finger foods; avoid giving large quantities at one time.
- Try offering fluids at different temperatures at different times for variety.
- Remember that children can ingest greater amounts of thin liquids (e.g., gelatin or carbonated drinks) than thicker liquids (e.g., cream soups or milkshakes).
- Include ice chips as fluid intake. Ice is approximately equivalent to half the same amount of water (e.g., 1 cup of ice equals a half-cup of water).
- Use straws (unless not allowed) and brightly colored utensils, cups, or dishes to provide contrast and stimulation.
- Offer the child choices; allow the child to choose what he or she wants from the menu.
- Avoid spicy or highly seasoned foods.
- Talk with the dietitian to see if any special preferences can be addressed.
- Offer praise to your child for what he or she eats or drinks.
- Never punish the child for not eating or drinking.
- Encourage the older child to help keep track of what he or she eats and drinks.

Providing Play, Activities, and Recreation for the Hospitalized Child

Play is an important component in the child's plan of care. Today many health care settings providing care for children have playrooms with age-appropriate toys, equipment, and other creative activities (Fig. 32.6). If the facility is large enough, there may even be a separate area for teens where they can listen to music, play video games, and visit with peers. Obviously, some children will not be able to use these facilities if their activity level is restricted or if isolation is necessary. Children may also play in their rooms. Ensure that opportunities for unstructured play are provided to all children who can engage in play.

FIGURE 32.6 Children occupied in a hospital playroom. It is important to provide age-appropriate activities for younger and older children alike.

Therapeutic play may be used to teach children about their health status or to allow them to work through issues in their lives.

▶ *Take* NOTE!

Avoid using the term "playroom" when caring for older school-aged children and adolescents. Instead, call it the "activity room" or "social room." Doing so promotes a greater feeling of maturity and makes it more likely that they will use the area.

Child Life Specialist

The **child life specialist** (CLS) is a specially trained individual who provides programs that prepare children for hospitalization, surgery, and other procedures that could be painful (Child Life Council, 2008). The CLS is a member of the multidisciplinary team and works in conjunction with the health care providers and parents to foster an atmosphere that promotes the child's well-being. Services provided by a CLS include:

- Nonmedical preparation for tests, surgeries, and other medical procedures
- Support during medical procedures
- Therapeutic play
- Activities to support normal growth and development
- Sibling support
- Grief and bereavement support
- Emergency room interventions for children and families
- Hospital preadmission tours and information programs
- Outpatient consultation with families (Child Life Council, 2007a)

▶ *Take* NOTE!

Keep the bed or crib and playroom as "safe" places. Perform invasive procedures such as venipunctures in the treatment room if possible. Never perform any nursing interventions in the playroom, no matter how nonthreatening they may appear to the nurse.

Unstructured Play

Unstructured play allows children to control events, ideas, and relationships. Encourage parents to bring small toys and favorite stuffed animals from home to make the child feel more comfortable in the strange environment of the hospital. Children also enjoy receiving small new toys as surprises when they are hospitalized. Many children enjoy diversional activities such as playing board games or electronic games, reading books, and watching TV, videos, or DVDs. Quiet activities appropriate to the child's developmental level provide the opportunity for play and encourage the use and development of fine motor skills even if the child is confined to bed. Infants and toddlers enjoy manipulating blocks and playing with stacking toys. The preschooler may enjoy coloring, dollhouses, or playing with plastic building blocks such as Legos. School-age children and adolescents may enjoy playing video games or building a model geared toward their developmental level.

Play as Part of Nursing Care

Play is also an important part of nursing care. Use play as appropriate while providing routine nursing care to the child. An example of the use of play in nursing care involves the school-age child's love of competition and games. To increase range of motion in a school-age child who is hospitalized for traction due to a fracture, have the child throw a soft sponge ball or beanbag ball into a hoop, and compete against the child. To increase deep breathing, encourage the child to blow bubbles or blow a whistle. To increase intake of fluids, help the child create a

graph to chart the number of glasses of fluids he or she drinks over a period of time. Award the child a sticker, baseball card, special pencil, or other small item if he or she reaches a certain level.

When using play as part of nursing care, it is important to evaluate the outcome of play. Play used in the manner described above should enhance the child's outcome. For example, for the child blowing bubbles, determine whether this activity enhanced coughing and deep breathing.

Therapeutic Play

WATCH & LEARN

Another important aspect of play is **therapeutic play**. Health care professionals use therapeutic play to help the child deal with the physical and psychological challenges of illness and hospitalization. Therapeutic play is nondirected and focuses on helping the child cope with feelings and fears. Supervised play with medical equipment in the hospital environment can help children work thorough their feelings about what has happened to them (Fig. 32.7). In a large hospital or a children's hospital, the CLS typically coordinates these activities. Goals include maintaining normal living patterns, minimizing psychological trauma, and promoting optimal development of the child. If a CLS is not available, the nurse provides this type of activity. There is a greater emphasis on the developmental and psychosocial implications of illness and hospitalization and validation of the child's voice.

In emotional outlet play or traumatic play, the child acts out or dramatizes real-life stressors. For example, using a wooden hammer and pegs, a soft sponge ball, or boxing gloves can allow the child to express anger over separation from family and friends. Commercial toys such as anatomically correct dolls and puppets have removable parts so children can see various organs of the body. Sometimes younger children "talk" to puppets and dolls, allowing them to express their feelings to a nonthreatening "person" about a specific situation or what they want from the health care provider. For example, the Shadow Buddies dolls mentioned earlier in the chapter provide a way of coping with a specific condition. The company creates an ostomy buddy who has a stoma, a cancer buddy with thinning hair and a chest catheter for chemotherapy treatments, and a heart buddy who has a chest incision and a repaired heart. If the child has a dressing, the doll can also get one.

FIGURE 32.7 The nurse supervises play with medical equipment to help the child work through her feelings about being hospitalized.

Other types of therapeutic play include drawing and supervised "needle play." Drawing is a way for the child to express his or her thoughts and feelings. Supervised "needle play" assists children who must undergo frequent blood work, injections, or intravenous procedures. A doll can receive an injection as the child works out his or her anger and anxiety. Keep in mind safety and the child's growth and development level before planning this type of directed play; an adult must always be present.

Promoting Schoolwork and Education During Hospitalization

Promote schoolwork and the child's typical activities while he or she is in the hospital. Determine the amount of this schoolwork by assessing the child's condition, the availability of teachers, and the family situation. Many children's hospitals have teachers at the hospitals; there may be classrooms too. These teachers work closely with the child's neighborhood school to continue schoolwork as the child's condition permits. Hospitals without the educational staff will rely on parents to coordinate with the child's school. Parents may bring in schoolbooks and the child's homework for completion while in the hospital. This connection to the child's school as well as interactions with peers helps maintain normalcy for the child and minimizes the disruption of everyday life.

Addressing the Needs of Family Members

Assess the factors that may influence the family's reaction to the child's hospitalization and plan the care of the child to accommodate some of these issues. Encourage families to have support systems in place before, during, and after hospitalization. Using good communication and tailoring nursing actions to the family's needs and preferences increase the parents' satisfaction with the health care setting (Marino & Marino, 2000).

Parents and Caregivers

As stated previously, the anxiety level of caregivers greatly affects the anxiety level of the child. Thus, it is important to help the family members work through their feelings. Common sources of parental anger when a child is hospi-

talized include visiting restrictions, an unexpected change in the child's health status, confusion resulting from conflicting or insufficient information provided by the hospital staff, and feeling undervalued in the care of their child (Griffin, 2003).

The importance of family involvement to the well-being of the child is reflected in the philosophies, policies, procedures, and physical environments where care is delivered. The philosophy of family-centered care places the family at the core of care. The family is the primary and continuing provider of care for the child. Encourage parents to room-in with the child throughout the hospital stay, if possible. Facilities can be designed to welcome family participation. For example, having computer ports and fax machines available and providing extra meals and beds for the parents can encourage parents to participate in care. View the parents as vital members of the health care team and partners in the care of the ill child.

Siblings

Family-centered care recognizes the need to treat the child in context of the family, including siblings. Important questions that will affect how siblings deal with the hospitalization of their brother or sister include:

- Was the admission an emergency?
- Were there previous admissions, and how did the siblings perceive those hospitalizations?
- How serious is the illness or trauma?
- Is the prognosis known?

Address the sibling's possible feelings of guilt. Use educational materials, allow time for visits, send photographs back and forth between siblings, and allow siblings to talk on the phone.

Providing Client Teaching

Not all experiences with hospitalization are negative: in fact, the experience may enhance the child's and family's coping skills, bolster self-esteem, and provide new socialization experiences. It may allow the child to master self-care skills and provides an opportunity for the child and family to learn new information. Parents may learn more about their child's growth and development skills as well as additional parenting or caregiving skills, resulting in improved parenting abilities. In addition, the child's overall health may be improved because of the hospital stay if the child receives current immunizations and the parents learn more about health care practices.

The overall goals of client and family teaching are to minimize the child's and family's stress, educate them about treatment and nursing care in the hospital, and ensure the family can provide appropriate care at home upon discharge. Providing support before, during, and after hospitalization may minimize stress. Preadmission programs can introduce the child and family to the setting. During the hospital stay, forming partnerships with the child and family, using strategies to promote coping, and providing appropriate preparation for procedures, tests, and surgery serve to decrease stress.

Assess the child's and family's knowledge of the illness and hospital experience. This provides a baseline for teaching. Include hospital rules in child and family teaching. Behavioral changes in hospitalized children often disturb parents or caregivers. Determine the child's usual patterns of behavior and explain to the parents about the child's reaction to hospitalization. Encourage the family to maintain consistent discipline even while in the hospital to provide structure for the child as well as to prevent discipline issues after discharge. Also discuss how siblings may react to the hospitalization, and provide appropriate teaching to the siblings. Every interaction the nurse has with the child or family provides an opportunity for teaching. Explain the purpose of even simple procedures such as vital signs assessment to the child and family. Provide ongoing information about the child's illness or trauma, treatment plan, and expected outcomes. Chapter 2 provides general principles related to teaching children and their families.

Preparing the Child and Family for Discharge

Discharge planning actually begins upon admission. The nurse assesses the family's resources and knowledge level to determine what education and referrals they may need. Upon discharge, children and their parents or caregivers receive written instructions about home care, and a copy is retained in the medical record. These instructions are individualized for the child. Generally, discharge instructions should include:

- Follow-up appointment information
- Guidelines about when to contact the physician or nurse practitioner (e.g., new or worsening symptoms or indications that the child is not improving)
- Diet
- Activity level allowed
- Medications, including dose, times to be given, route, adverse effects, and special instructions; any prescriptions should be included
- Information on additional treatments the child requires at home
- Specific dates for when the child may return to school or daycare
- Names and phone numbers of agencies the family has been referred to, such as durable medical equipment providers

Provide and review educational booklets that give basic health information or general care for a child with a

FIGURE 32.8 The nurse uses charts with pictures to perform client teaching before the child goes home.

particular disease (Fig. 32.8). Videotapes, DVDs, or CD-ROMs may also be used if available. The ability to watch a procedure over and over is helpful to some families. Explain, demonstrate, and request a return demonstration of any treatments or procedures to be done at home. Provide a written schedule if the child is to receive multiple medications, tube feedings, or other medical treatments. For complicated cases, a written teaching plan may be used to provide continuity of child/family education between various nurses. As the family attempts to perform each task, document whether the caregiver continues to require assistance or prompting with the task or whether he or she can perform the task independently.

Parents of children with multiple medical needs may benefit from a trial period of home care. This occurs while the child is still in the hospital, but the parents or caregivers provide all of the care that the child requires. Support the family and praise their accomplishments during this trial period.

Key Concepts

- Stressors associated with hospitalization include separation from family and routines; fear of an unknown environment; potential for pain, bodily injury, or mutilation; and loss of control.
- Responses of children to the general stressors of hospitalization include anxiety, fear, anger, guilt, and regression.
- Parents may experience anger or guilt related to the hospitalization of their child.
- The responses of children and families to hospitalization can be influenced by the age and developmental level of the child, their perceptions of the situation, previous experiences, separation from family and peers, coping skills, and the preparation and support provided by the family, facility, and health care providers.
- Whatever the reason for admission, preparation for admission is vital.
- Upon admission to the hospital or outpatient unit, orient the child and family to the unit, discuss unit rules, and begin patient/family teaching.
- Since due to their age and developmental level children may be vulnerable to harm, the nurse must use appropriate safety measures in caring for children (e.g., identification of children, use of restraints and transportation, basic hygiene measures).
- Nursing care is directed toward meeting the child's needs related to self-care, separation anxiety, growth and development, diversion, family, control, teaching, pain relief, and coping.
- Play, including therapeutic play, is an important strategy to prepare children for hospitalization and to help them adapt to the effects of illness and hospitalization. It provides an emotional outlet, opportunities for teaching and learning, and the ability to become familiar with a situation and improve physiologic abilities. A child life specialist is a specially trained individual who is a member of the child's multidisciplinary team. He or she works in conjunction with the child's health care providers and parents to foster an atmosphere that promotes the child's well-being.
- Family-centered care and atraumatic care are philosophies that pay special attention to the concerns of the family and child during hospitalization.
- Providing support to hospitalized children and their families is critical for minimizing stress.
- Discharge planning begins upon admission. Each interaction with the family is an opportunity for patient teaching.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. The nurse would most likely assess separation anxiety in which of these children?
   a. A 2-month-old infant
   b. A 15-month-old toddler
   c. A 4-year-old preschooler
   d. An 11-year-old child
2. When developing the preoperative plan of care for an adolescent, the nurse plans interventions to address the adolescent's anxieties and fears related to:
   a. Separation from parents
   b. Punishment for wrongdoing
   c. Changes in body image
   d. Magical thinking
3. The nurse is preparing a 5-year-old boy for surgery on his lower leg. His mother is helping him into the hospital gown and the boy fights removal of his underwear. What is the most appropriate nursing action?
   a. Allow the mother to remove the underwear.
   b. Tell the boy he is acting childishly.
   c. Notify the OR that the underwear is on.
   d. Allow the boy to keep his underwear on.
4. A 6-month-old infant requires restraint to prevent removal of his nasogastric tube. What is the priority nursing intervention?
   a. Tie the restraint loosely to prevent skin breakdown.
   b. Leave the baby unrestrained when directly observed.
   c. Position the restrained infant prone to prevent aspiration.
   d. Place the infant in a room near the nurses' station.
5. A 10-year-old child on a regular diet refuses to eat the food on her meal tray. She requests chicken nuggets, French fries, and ice cream. What is the best nursing action?
   a. Ask that the child's desired foods be sent up from the kitchen.
   b. Negotiate with the child to eat at least part of the food on the tray.
   c. Remove a privilege.
   d. Offer the child cereal and milk from stock on the nursing unit.

CRITICAL THINKING EXERCISES

1. Becky, an 8-year-old, is admitted to the pediatric unit for an emergency surgery. She is in third grade and very active in after-school programs. Her mother is with her during the admission process but will have to return to work shortly after Becky returns from surgery to the pediatric unit. Would the nurse expect Becky to show separation anxiety? What are the three top nursing diagnoses for Becky?
2. A 6-year-old is admitted to the general pediatric unit after spending several hours in the emergency department with an acute asthma attack. Her mother and two younger siblings are present, but the mother plans to leave shortly to take the siblings home. The father will visit in about 2 hours, after work. What is the overall goal for this child's care? What could the nurse say to promote coping in this child? What would be the best answer if the mother asks if she should stay?

STUDY ACTIVITIES

1. Shadow a child life specialist in a hospital. Identify his or her role and how he or she works with the nursing staff.
2. Follow a child and family during the admission process, from preadmission to initial time on the unit, to identify the procedures and tasks involved. Examine the response of the child and family and how the nursing staff responds to their needs.
3. Spend a day in radiology or the emergency room to learn about the strategies used to prepare children for various procedures.
4. Develop a teaching plan to orient a toddler or preschooler and his or her family to a nursing unit. Include the resources, personnel, and techniques to include in the teaching plan.

CHAPTER 33

Nursing Care of the Child With Special Needs

KEY TERMS

chronic illness
developmental delay
developmental disability
palliative care
respite care
terminal illness

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Analyze the impact that being a child with special needs has on the child and family.
2. Describe ways that nurses assist children with special needs and their families to obtain optimal functioning.
3. Identify anticipated times when the child and family will require additional support.
4. Plan for transition of the special needs child from the inpatient facility to the home, and from pediatric to adult medical care.
5. Discuss early intervention and public school education for the special needs child.
6. Differentiate developmental responses to death and appropriate interventions.
7. Discuss key elements related to pediatric end-of-life care.

Preet Singh, a 2-year-old boy who was born at 27 weeks' gestation, is seen in your clinic for the first time. He has a history of hydrocephalus and developmental delay. During the examination, his mother states, "I'm concerned about finding a good, affordable preschool for Preet. His older brother attends public school, but I can't imagine Preet there." After further discussion with Preet's mother, you realize he has not been involved in an early intervention program.

Wow

The touch of a mother's hand and the sound of her voice bring comfort to her special child, and when you bring comfort, you strengthen both of them.

As medicine and scientific technology have advanced, the number of children surviving with health problems that require long-term interventions has increased significantly (Hewitt-Taylor, 2005). Children are now living with conditions that require high-tech treatments for survival. The Maternal Child Health Bureau defines children with special health care needs as those who have or are at risk for a chronic physical, developmental, behavioral, or emotional condition beyond needs generally required by children (Jackson Allen, 2004). According to the National Survey of Children with Special Health Care Needs, about 12.8% of children in the United States have special health care needs. Of those children with special needs, almost 25% are reported as having conditions that affect their activities usually, always, or a great deal of the time (U.S. Department of Health and Human Services, 2004).

In addition to the direct effects of their special needs, these children and their families are often inadequately insured, have financial needs, have unmet family support needs, or have difficulty obtaining the specialty care that the child requires. Nationwide, 11% report not having a personal doctor or nurse ("medical home") (U.S. Department of Health and Human Services, 2004). Children with special health care needs generally require more intensive and diverse health services, as well as coordination of those services, than do typical children (Child and Adolescent Health Measurement Initiative, 2006). It can be challenging for the family of a child with special needs to navigate the system and obtain all of the services their child requires.

Another difficult situation that families may encounter is losing a child to the disease process. A child's chronic illness may progress to the point of becoming terminal. Despite the increased survival rates for children with cancer as a result of improved treatment options and protocols, cancer remains the leading cause of death from disease in all children over the age of 1 year. Less frequently, other diseases also lead to **terminal illness** in children, with congenital defects and traumatic injuries being the more common causes. Caring for the dying child is a family-centered, multidisciplinary process. Nurses must respond to the child's and family's physiologic, emotional, and spiritual needs during this difficult time. Children display differing responses to the dying process and impending death depending on their developmental level. Children and their families need significant amounts of support throughout the process of dying.

For children with special needs, the pediatric nurse fills the critical role of child and family advocate and case manager. When a child is dying, nurses provide physical care of the child and also strive to meet the emotional needs of the child and family. Nurses are in a unique position, both in the inpatient and outpatient setting, to have a significant and positive influence on the lives of these children and their families.

The Medically Fragile Child

When an infant is born very prematurely, when a child is injured and requires long-term rehabilitation and special care, or when a child is diagnosed with a complex chronic health condition, the parents are often devastated initially. The parents of medically fragile children may feel they must adapt to the risk and protect their child. They are interested in preserving their family while compensating for the past, and they cautiously look to the future and become hopeful again. While the infant or child is still in the hospital, nurses can help parents build on their strengths, empowering them to care for their medically fragile infant or special needs child. Education is paramount and should begin as early in the hospitalization as possible. In many situations, particular discharge needs are known early in the course of the infant's or child's hospitalization. Nurses should provide anticipatory guidance about the course of treatment and the expected outcome.

Most children with **chronic illness**, or those who are dependent on technology, progress through stages of growth and development just as typical children do, though possibly at a slower pace. The exception is the child with significant psychomotor retardation, though some developmental progression may occur. Children with special health care needs desire to be treated as normal (Wang & Barnard, 2004), and they want to experience the same events that other children do.

Of particular concern is a growing subset of children with emotional, behavioral, and developmental problems. Children with these needs have even greater difficulty receiving the care and services they require. Many children with emotional, behavioral, or developmental problems also have health problems. Often, these children's problems are not diagnosed early and treatment is difficult. Ongoing counseling and therapy is very difficult for some families to obtain (CDC, 2005). Ultimately, this has a negative impact on the child's physical and mental health and may result in decreased achievement and productivity as the child matures. See Healthy People 2010.

HEALTHY PEOPLE 2010

Objective	Nursing Significance
Reduce the proportion of children and adolescents with disabilities who are reported to be sad, unhappy, or depressed.	Screen children with special health care needs for depression or sadness. Refer children and their families to mental health providers as needed.

Effect of Special Needs on the Child and Family

The child with special needs and his or her family are both affected by the child's condition and way of living. Each member of the family experiences effects related to the child's special needs. Family members' experiences and their responses to the child's illness influence each other directly. They also affect the coping ability of the child with special needs. Children's ability to cope is significantly affected by the family's response to stressors.

Effects on the Child

Children with special health care needs experience differing effects of the chronic illness or disability based on their developmental level, which naturally changes over time for most children.

Infants may fail to develop a sense of trust or attach appropriately with the parents because of frequent hospitalizations, often with multiple caregivers involved, lack of consistency in nurturing, or parental detachment or grieving over the child's condition. The infant's ability to learn through sensorimotor exploration may be impaired due to lack of appropriate stimulation, confinement to a crib, or increased contact with painful experiences.

The toddler may experience difficulty developing autonomy because of increased dependency on the parent or overinvolvement by the parent. Motor and language skill development may be delayed if the toddler is not given adequate opportunities to test his or her limits and abilities.

Limited opportunity also reduces the preschooler's development of a sense of initiative. The preschooler may experience limited opportunities for socialization, causing him or her to withdraw or to feel criticized. Body image development may be hindered due to painful exposures and anxiety. In preschoolers, magical thinking may lead to feelings of guilt for having caused their own disease or condition.

The school-age child may have limited opportunities to achieve a sense of industry because of school absence and inability to participate in activities or competitive events. Lack of socialization limits the school-age child's ability to form peer relationships. The ability to learn via concrete operations is affected by the child's physical limitations or possibly the treatments required.

Adolescents may feel as though they are different from their peers because of their lack of skills/abilities or their appearance. This may hinder the teen's ability to form a sense of personal identity. Since the teen with special health care needs often requires significant amounts of support from the parents, it may be difficult for the adolescent to achieve independence. If the earlier stages of cognitive development have been delayed, then reaching the level of abstract thinking may be blocked.

The child with special health care needs may be able to focus on the positive experiences in his or her life as a method of coping, leading to as much independence as possible. Other children may always feel different from their peers (in a negative sense) and withdraw. Irritability and acting out may also occur. Some children may be compliant and/or seek support for themselves. The child's coping pattern may change over time or with certain situations, such as relapse or worsening of the condition. Children with overprotective parents may display marked dependence and may be very fearful. Children whose parents have been overly indulgent may be more independent and defiant. The nurse must assess the child's individual response to the current health care status and intervene as appropriate.

Effects on the Parents

Raising a child with special needs is generally not the life parents expected to have. Some parents may adapt over time and ultimately accept the child's illness or disability. Others may adapt but do not accept the child's condition and experience the continual fading and re-emergence of chronic sorrow. Denial of their child's problem may prevent parents from progressing through grief, but it also allows them to have hope (Rolland & Walsh, 2006).

Caring for the special needs child at home (rather than having the child in a facility) may decrease the parents' feelings of anxiety and helplessness (Fig. 33.1). As with typically developing children, parents enjoy witnessing the emotional and social growth of the child (Wang & Barnard, 2004). Parents of special needs children experience a multitude of emotions and changes in their lives; they report that they "live worried" (Coffey, 2006). They feel helpless and overwhelmed at discharge from the hospital. Though willing to carry the burden, they may experience fear, anger,

FIGURE 33.1 The special needs child often requires a significant amount of care at home.

sadness, guilt, frustration, or resentment. Many parents experience grief as a result of losing the "perfect child" they dreamed of.

Stressors of Daily Living

Families with a child who has special health care needs experience life differently than other families. They may have to change their housing situation to accommodate the child's needs. Their sleep is affected. Constant supervision of the technology-dependent child makes it difficult to carry out other basic household activities. In addition to basic childcare and running of the household, medical and technical care must be incorporated into daily life. The family's identity and the parents' employment may be altered radically. Holidays and vacations are affected, as it is difficult to plan activities. Nursing and other health care professional visits are disruptive to family life.

Mothers appear to carry the larger burden of care, though fathers are not unaffected. Somehow, parents eventually take charge, and though they fear failure, they display vigilance, can negotiate and seek information, and become advocates for their child and experts on his or her care. Though parents may feel trapped, isolated, and experience a loss of freedom, their need to survive as a family continues to motivate them. Parents may feel a need to be with their child at all times and experience stress related to coping with the heavy load of caregiving (Case-Smith, 2004).

The extended burden of caregiving can also have adverse health effects on caregivers: only a small percentage of parents of children with special health care needs report that they routinely participate in health-promoting activities for themselves (Kuster et al., 2004). Additionally, parents of children with special health care needs are at increased risk for the development of depression (Wang & Barnard, 2004).

In addition to the caregiving burden, parents experience role conflicts, financial burdens, and the struggle between independence in providing care and the isolation associated with it. It is very difficult to enjoy spontaneous events outside the home because so much planning is necessary (Case-Smith, 2004).

The possibility of independence revolves around mobility issues, education, and assistive technology. Though education for all children is federally mandated, parents have anxiety about educational decisions and also find it difficult to obtain the support and educational services the child needs.

Additional stress is associated with transition times in the care of a special needs child. These transition times include:

- Initial diagnosis or change in prognosis
- Increased symptoms
- When the child moves to a new setting (hospital, school)
- During a parent's absence
- During periods of developmental change

Vulnerable Child Syndrome

"Vulnerable child syndrome" is a clinical state in which the parents' reactions to a serious illness or event in the child's past continue to have long-term psychologically harmful effects on the child and parents for many years. The parents view the child as being at higher risk for medical, developmental, or behavioral problems (Kerruish et al., 2005). Parents exhibit excessive unwarranted concerns and seek health care for their child very frequently. Risk factors for the development of vulnerable child syndrome include preterm birth, congenital anomaly, newborn jaundice, handicapping condition, an accident or illness that the child was not expected to recover from, or crying or feeding problems in the first 5 years of life (Pearson & Boyce, 2004). The parent has difficulty separating from the child, and the child senses that anxiety and then develops symptoms that reinforce the parent's fears. Alternatively (or additionally), the parents may to try to retain control, particularly at times of increasing independence, and fear disciplining the child as they do not want to "upset" the child (Pearson & Boyce, 2004).

Effects on Siblings

The siblings of children with special health care needs are also affected dramatically. Their relationship with their parents is different than it would have been if they had a typical brother or sister. Parents often need to spend more time with the child with special needs and have less time with their healthy children. Children exhibit emotional and psychological responses to their sibling's long-term needs. Knowledge about the sibling's illness, attitude toward and adjustment to it, the sibling's own self-esteem, how socially supported the sibling is, and the parents' awareness of sibling's feelings are all related to how well the sibling adjusts (Hewitt-Taylor, 2005).

Nursing Management of the Medically Fragile Child

Family-centered care provides the optimal framework for caring for medically fragile children and their families. Family-centered care minimizes the impact of chronic illness and maximizes the child's developmental potential. To provide the best nursing care for these children and the families, the nurse must first develop a trusting relationship with the family.

To ensure optimal functioning, children with special health care needs require comprehensive and coordinated services from multiple professionals. These professionals should work collaboratively to address the child's health, educational, psychological, and social service needs (Farmer, 2005). In addition to case management and advocacy, nursing management focuses on screening and ongoing assessment of the child, provision of home care, care of the technology-dependent child, education and support of the child and family, and referral for resources.

Developing a Therapeutic Relationship

Raising children is always challenging, but for the parent of a special needs child it is often overwhelming and exhausting. The parents' needs change continuously, so it is best if the family has a permanent relationship with a health care provider. This promotes trust and a more efficient two-way flow of information (Nuutila & Salanterä, 2006).

Respect the parents' range of emotions and work with them as a team to manage the child's care. Parents need to be recognized for complying with the treatment plan or for other small gains that are made (Jackson Allen, 2004). Empowering the family strengthens them and gives them self-confidence (Lindblad et al., 2005). Feeling supported and invigorated gives parents strength, energy, and hope. Box 33.1 lists principles related to family involvement.

Screening and Ongoing Assessment

Nurses should perform screening to identify children with unmet health care needs (Jackson Allen, 2004). A screening tool developed by the Child and Adolescent Health Measurement Initiative (Fig. 33.2) may help to identify children with special health care needs. Additional information related to the screening tool is available at http://www.cahmi.org/pages/Sections.aspx?Section=10.

Children with special health care needs may attain developmental milestones more slowly than typically developing children. If the Denver II is used for ongoing developmental surveillance of the young child, then the results should be compared from visit to visit to determine progress rather than using it as a screening tool. Assess special needs children and their families for vulnerable child syndrome.

Promoting Home Care

Home is the most developmentally appropriate environment for all children, even those who are technology dependent. The child's home provides an emotionally nurturing and socially stimulating environment. Children desire to be cared for at home, and those who are cared for at home display an improved physical, emotional, psychological, and social status (Wang & Barnard, 2004).

Technology-dependent children may require supplemental oxygen, assisted ventilation, tracheostomy care, assisted enteral or parenteral feeding, or parenteral medication administration. Traditionally, hospitalization would have been required for these children—in fact, intensive care would have been necessary for children who need assisted ventilation—but with advances in technology, today even children with extensive medical and developmental needs may be cared for at home. Early discharge planning is important, and parents will need detailed instructions and support in caring for the technology-dependent child at home.

Early Discharge Planning

Early discharge planning and ongoing inclusion and education of the family facilitates continuity of care (Swartz, 2005). Box 33.2 provides information about preparing the medically fragile child for discharge.

Caring for the Technology-Dependent Child at Home

Home care nurses are often involved in the care of technology-dependent children. Caring for a technology-dependent child at home is a complex process, yet children thrive in the home care setting with appropriate intervention and care. Many parents feel that rearing a technology-dependent child is different only because of the presence of the equipment. Nurses may tend to think that parents treat the technology-dependent child differently than the other children, while parents value normalization and want to raise and provide discipline to all of their children in the same manner. Parents should tell nurses about their child-rearing expectations, and nurses need to respect the parents' wishes.

Improved collaboration between parents and home care nurses may decrease the parents' stress and maximize opportunities for appropriate growth and development in the technology-dependent child. Thus, a strong relationship, good communication, and negotiation skills are assets to the family and child.

Help the family to incorporate the medical regimen into daily life to minimize the child's self-perception of being "different" (Green & Ray, 2006). Teach families about the technical issues, such as home and travel oxygen therapy, use of the ventilator, suctioning, chest percussion and postural drainage, tube feedings and care of the feeding tube, and medications. Assist parents with the planning and management of routine care, respiratory treatments, nutritional support, and developmental interventions. Reinforce exercises and techniques as prescribed by developmental therapists (Romanko, 2005). Refer to Chapter 2 for additional information about home care nursing.

(text continues on page 1016)

BOX 33.1 Principles Related to Family Involvement

Families:

- Define who they are and their culture
- Need to have their basic needs met
- Need to have access to information and training
- Deserve to receive culturally competent care
- Can identify priorities and concerns that lead to policy change
- Know their strengths, limitations, and fears
- Share decision-making power and responsibility for outcomes

Adapted from Federation of Families for Children's Mental Health. (2007). *FFCMH principles for family involvement.*

CAHMI Children with Special Health Care Needs (CSHCN) Screening Tool
(mail or telephone)

1. Does your child currently need or use **medicine prescribed by a doctor** (other than vitamins)?
   - ☐ Yes ⇐ Go to Question 1a
   - ☐ No ⇐ Go to Question 2

   1a. Is this because of ANY medical, behavioral or other health condition?
   - ☐ Yes ⇐ Go to Question 1b
   - ☐ No ⇐ Go to Question 2

   1b. Is this a condition that has lasted or is expected to last for *at least* 12 months?
   - ☐ Yes
   - ☐ No

2. Does your child need or use more **medical care, mental health or educational services** than is usual for most children of the same age?
   - ☐ Yes ⇐ Go to Question 2a
   - ☐ No ⇐ Go to Question 3

   2a. Is this because of ANY medical, behavioral or other health condition?
   - ☐ Yes ⇐ Go to Question 2b
   - ☐ No ⇐ Go to Question 3

   2b. Is this a condition that has lasted or is expected to last for *at least* 12 months?
   - ☐ Yes
   - ☐ No

3. Is your child **limited or prevented** in any way in his or her ability to do the things most children of the same age can do?
   - ☐ Yes ⇐ Go to Question 3a
   - ☐ No ⇐ Go to Question 4

   3a. Is this because of ANY medical, behavioral or other heath condition?
   - ☐ Yes ⇐ Go to Question 3b

   - ☐ Yes ⇐ Go to Question 5a
   - ☐ No

   5a. Has this problem lasted or is it expected to last for *at least* 12 months?
   - ☐ Yes
   - ☐ No

FIGURE 33.2 The CSHCN Screener. (Reprinted with permission from the Child and Adolescent Health Management Initiative.)

Scoring the Children with Special Health Care Needs (CSHCN©) Screening Tool

Conceptual background

The CSHCN Screener uses consequences-based criteria to screen for children with chronic or special health needs. To qualify as having chronic or special health needs, the following set of conditions must be met:

a) The child currently experiences a specific consequence.
b) The consequence is due to a medical or other health condition.
c) The duration or expected duration of the condition is 12 months or longer.

The first part of each screener question asks whether a child experiences one of five different health consequences:

1) Use or need of prescription medication
2) Above-average use or need of medical, mental health or educational services
3) Functional limitations compared with others of same age
4) Use or need of specialized therapies (OT, PT, speech, etc.)
5) Treatment or counseling for emotional or developmental problems

The second and third parts* of each screener question ask those responding "yes" to the first part of the question whether the consequence is due to any kind of health condition and if so, whether that condition has lasted or is expected to last for at least 12 months.

**NOTE: CSHCN screener question 5 is a two-part question. Both parts must be answered "yes" to qualify.*

All three parts of at least one screener question (or in the case of question 5, the two parts) must be answered "yes" in order for a child to meet CSHCN Screener criteria for having a chronic condition or special health care need.

The CSHCH Screener has three "definitional domains." These are:

1) Dependency on prescription medications
2) Service use above that considered usual or routine
3) Functional limitations

The definitional domains are not mutually exclusive categories. A child meeting the CSHCN Screener© criteria for having a chronic condition may qualify for one or more definitional domains (see diagram below).

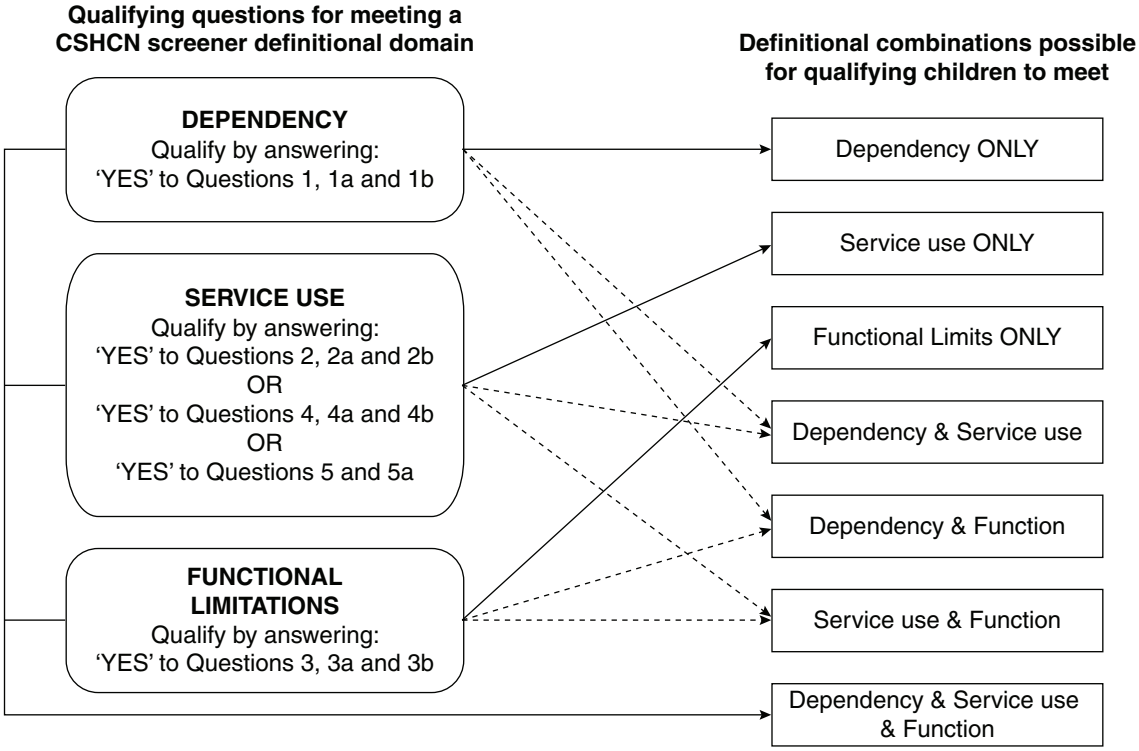

FIGURE 33.2 (continued)

BOX 33.2 Preparing for Home Care Before Discharge

- Promote liaison with community resources. Develop communication between various services. Plan appointments. Set up home nursing care (either private duty or visits).
- Teach skills, encouraging active caregiving in the hospital setting to increase the parents' self-confidence
- Discuss psychological and emotional issues with parents.
- Obtain/organize equipment and supplies (running out of supplies may cause significant stress on families).
- Refer the family for necessary financial resources.
- Ensure the family's home environment is adequate (enough room for equipment, electricity on, air conditioner for warm weather, heater for cold weather, and refrigeration for food).
- For the baby being discharged from the NICU:
  - Teach the parents about the infant's cues and behaviors and the preemie's different sleep–wake patterns.
  - Encourage kangaroo care and infant massage while in the NICU (as the infant's condition allows).
  - Educate the parents about possible effects on short- and long-term neurodevelopment.
  - Refer to local early intervention program.
  - Assist the family with finding a primary care provider who is experienced in the ongoing follow-up of high-risk infants.

Data from Bakewell-Sachs, S., & Genarro, S. (2004). Parenting the post-NICU premature infant. *MCN, 29*(6), 398–403; and Hewitt-Taylor, J. (2005). Caring for children with complex and continuing health needs. *Nursing Standard, 19*(42), 41–47.

BOX 33.3 Nursing Interventions for Families of Children with Special Health Care Needs

- Flag the special needs child's chart.
- Develop written health plans.
- Provide care coordination and collaboration with specialists in other disciplines, early intervention, schools and public agencies.
- Address needs for prior authorization for treatments, medication or specialist referrals; retain copies in the child's chart of authorization forms and approvals.
- Modify office routines to promote family and child comfort.
- Assist parents with childcare decisions. Help parents to understand the child's limits and abilities and the potential health issues (e.g., infections and injuries) associated with childcare.
- Know community resources available to children with special health care needs.
- When the child is hospitalized, encourage high levels of parental participation (if desired by the parent).
- Provide care coordination across multiple health settings.
- Educate childcare providers on child health needs.
- Help parents get involved with parent support networks.

Data from Jackson Allen, P. L. (2004). Children with special health care needs: National survey of prevalence and health care needs. *Pediatric Nursing, 30*(4), 307–314; and Onufer, C. N. (2006). New momentum on building a medical home for the child with a chronic health problem. *Contemporary Pediatrics, 23*(10), 65–66, 66–70, 72–73.

Providing Care Coordination

Once a child with special health care needs has been identified and has been discharged to the home setting, the nurse plays a vital role in care coordination. Any child with special health care needs benefits from a medical home. The nurse in the medical home is a critical team member, providing ongoing care coordination and follow-up. If such services are available in the local area, refer the child and family with special needs to an integrated health program that provides interdisciplinary, collaborative care for children requiring complex, coordinated care. Box 33.3 lists nursing interventions for families of children with special health care needs.

Providing Ongoing Follow-Up of the Former Premature Infant

Many former premature infants experience a myriad of medical and developmental problems throughout infancy, early childhood, and beyond. Upon or following discharge, many former premature infants display one or many of the following medical or developmental problems:

- Chronic lung disease (bronchopulmonary dysplasia)
- Cardiac changes such as right ventricular hypertrophy and pulmonary artery hypertension
- Growth retardation, poor feeding, anemia of prematurity, other nutrient deficiencies
- Apnea of prematurity, gastroesophageal reflux disease, bradycardia
- Sudden infant death syndrome (SIDS)
- Rickets (osteopenia) of prematurity
- Hydrocephalus, ventriculomegaly, abnormal head MRI results, ventriculoperitoneal shunt
- Inguinal or umbilical hernias
- Retinopathy of prematurity, strabismus, decreased visual acuity
- Hearing deficits
- Delayed dentition
- Gross motor, fine motor, and language delay, sensory integration issues

Over the long term, former premature infants are at higher risk than typical infants of developing cognitive delay, cerebral palsy, attention-deficit disorder, learning disabilities, difficulties with socialization, and vulnerable child syndrome. Additionally, many former premature infants display alterations in muscle tone at or shortly after discharge from the neonatal intensive care unit (NICU) that require physical therapy intervention.

For these reasons, high-risk infants require special attention and thorough, appropriate assessment to discern subtle changes that may affect their long-term physical, cognitive, emotional, and social outcome. The pediatric nurse should have an understanding of the special concerns that former premature infants and children as well as their families may face.

From the beginning, encourage families to keep a binder that includes all of the infant's pertinent check-up, insurance, and medical and developmental information; this will serve as a resource for the parents, and they will be able to supply complete information when visiting various providers (Kelly, 2006c).

Providing Routine Well-Child Care of the Former Premature Infant

Former premature infants require similar well-child care as typical infants do, with additional visits for management of multiple complex medical issues and developmental screening/intervention. Teach families routine newborn care, including bathing, dressing, and avoidance of passive cigarette smoke. All visits for primary care follow-up will be scheduled based on the infant's chronological age.

Prior to discharge from the NICU, the infant will be tested for oxygen desaturation while seated in the car seat. Clearance will be obtained prior to the infant's discharge. Former preemies require car seat use just as other infants do. Help the parents to find methods of padding the car seat or adding an additional semi-firm cushion inside the seat for the infant to ride in the car safely. Some infants may need to continue cardiac/apnea monitoring while in the car seat.

Since the former premature infant is at increased risk for SIDS compared to the general population, it is critical to teach parents to put the infant on his or her back to sleep (although this is contraindicated with gastroesophageal disease).

Give immunizations according to the current CDC-recommended immunization schedule, based on the infant's chronological age (Kelly, 2006a). All former preemies should receive the flu vaccine as recommended after 6 months chronological age. Respiratory syncytial virus (RSV) prophylaxis is critical for certain groups of premature infants. Administer palivizumab (Synagis) vaccine according to the recommended schedule (refer to Chapter 39 for additional information about RSV prophylaxis) (Kelly, 2006b; Romanko, 2005).

Assessing Growth and Development of the Former Premature Infant

When assessing growth and development of the infant or child who was born prematurely, determine the child's adjusted or corrected age so that you can perform an accurate assessment. The corrected or adjusted age should be used for evaluating progression in growth as well as development. For example, if a 6-month-old infant was born at 28 weeks' gestation (12 weeks or 3 months early), his growth and development expectations are those of a 3-month-old (corrected age). Continue to correct age for growth and development until the child is 3 years old.

Many former premature infants require special diets to foster catch-up growth. Extra calories are needed for increased growth needs. Additional calcium and phosphorus are required for bone mineralization. For these reasons, former preemies should be fed breast milk fortified with additional nutrients or a commercially prepared formula specific for premature infants. When former preemies demonstrate consistent adequate growth (usually by 6 months corrected age), they may be switched to a "term infant formula" such as Similac or Enfamil, concentrated to higher caloric density if needed. Assess the infant's ability to suck efficiently and refer him or her to occupational or speech therapy if the infant is a slow feeder or has difficulty feeding.

All anticipatory guidance related to nutrition is based on the child's corrected age. In other words, begin solids at 6 months corrected age, not chronologic age, and delay the addition of whole milk until 12 months corrected age, rather than 1 year chronologic age. Signs that the former premature infant may be ready to attempt spoon feeding include interest in feeding, decrease in tongue thrust, and adequate head control (Kelly, 2006a).

Early screening and intervention for issues related to development are critical to the attainment of optimal development in the former preemie. The comorbidities that ex-preemies exhibit in the form of prior and current medical problems place these infants at high risk for **developmental delay** (Kelly, 2006b). Even mild developmental delays warrant evaluation and intervention. The Denver II may be used as a screening tool for developmental concerns in the ex-preemie, though it does not always identify children at risk. Parent-report questionnaires demonstrate fairly accurate estimations of developmental problems, and their use is recommended by the American Academy of Pediatrics (AAP, 2006). Most importantly, assess the child's development based on corrected age until the child is 3 years old. Refer infants and children early if developmental concerns are suspected.

Identifying and Managing Failure to Thrive and Feeding Disorders in Children With Special Needs

Failure to thrive (FTT) is a term used to describe inadequate growth in infants and children. The child fails to

demonstrate appropriate weight gain over a prolonged period of time. Length or height velocity and head circumference growth may also be affected. Typical children may experience FTT, but it is much more common in the child with special needs. Adequate nutrition is critical for appropriate brain growth in the first 2 years of life and obviously for growth in general throughout childhood and adolescence. **Developmental disability** may contribute to FTT, as the child's ability to consume adequate nutrition is impaired because of sensory or motor delays, such as with cerebral palsy. Other organic causes of failure to thrive include inability to suck and/or swallow correctly, malabsorption, diarrhea, vomiting, or alterations in metabolism and caloric/nutrient needs associated with a variety of chronic illnesses. Infants and children with cardiac or metabolic disease, chronic lung disease (bronchopulmonary dysplasia), cleft palate, or gastroesophageal reflux disease are at particular risk. Feeding disorders or food refusal may occur in infants or children who have required prolonged mechanical ventilation, long-term enteral tube feedings, or an unpleasant event such as a choking episode. Inorganic causes of FTT include neglect, abuse, behavioral problems, lack of appropriate maternal interaction, poor feeding techniques, lack of parental knowledge, or parental mental illness. Poverty is the single greatest contributing risk factor (Block et al., 2005).

The two categories of causes are not mutually exclusive. Organic causes of FTT may lead to behavioral problems that potentiate problems with adequate growth; hence FTT is thought of as a multifactorial problem.

Screen all children for FTT to identify them early (Locklin, 2005). In addition to poor growth, the infant or child with FTT may present with a history of developmental delay or loss of acquired milestones. Infants or children with feeding problems may display nipple, spoon, or food refusal; difficulty sucking; disinterest in feeding; or difficulty progressing from liquid to puréed to textured food. Perform a detailed dietary history and instruct the parents to complete a 3-day food diary to identify what the child actually eats and drinks. Assess the parent–child interaction, with particular attention to the parent's ability to read and respond to the infant's or child's cues. Observe feeding, noting the child's oral interest or aversion, oral–motor coordination, and swallowing ability, as well as parent–child interactions before, during, and after the feeding (Block et al., 2005). Further aversion to eating may occur as the parent's anxiety over the thought of the child not eating or losing weight leads to attempts to force-feed the child.

Significant FTT may require hospitalization for evaluation and management. Sometimes enteral tube feedings are necessary in order for children with FTT or feeding disorders to demonstrate adequate growth. Box 33.4 lists nursing interventions for the hospitalized child with FTT.

BOX 33.4 Nursing Interventions During Hospitalization for Failure to Thrive

- Observe parent/child interactions, especially during feedings.
- Develop an appropriate feeding schedule.
- Provide feedings as prescribed (usually 120 kcal/kg/day is needed to demonstrate proper weight gain).
- Weigh the child daily and maintain strict records of intake and output.
- Educate parents about proper feeding techniques and volumes.
- Provide extensive support to alleviate parental anxiety related to the child's inability to gain weight.

▶ ***Take*** *NOTE!*

Infants with FTT related to maternal neglect may be less interactive than other infants and avoid eye contact.

Promoting Growth and Development

When caring for the infant with special health care needs in the hospital, provide consistent caregivers to encourage the infant to develop a sense of trust. Allow and encourage the parent to stay with the infant, providing a comfortable place for the parent to sleep. To promote attachment, emphasize the baby's positive qualities. Encourage developmentally appropriate skills and allow the infant to have pleasurable experiences through all of the senses.

For the toddler, begin developmentally appropriate limit-setting and discipline. Encourage independence as the toddler is able. Modify gross motor and sensory activities to accommodate the toddler's limitations. To encourage a sense of control, offer the toddler simple choices. As the preschooler develops, encourage mastery of self-help skills as the child is able. Encourage socialization with same-age peers to develop a sense of friendship. Reinforce to the child that the illness or disability is not a punishment for wrongdoing or the child's fault in any way.

Encourage the school-age child to attend school and make up work that must be missed for medical treatments or appointments. Provide education to the school staff and other students about the child's special needs. Promote involvement in appropriate sports activities; music, drama, or art activities; and clubs such as Boy Scouts or Girl Scouts. Educate the child about the illness or disability and the course of treatment.

Inform parents of teens that those with chronic illness often participate in the same activities as typical teens, such

EVIDENCE-BASED PRACTICE 33.1
Life Skills Intervention for Children With Cystic Fibrosis and Effects of Intervention on Psychosocial Adjustment, Functional Health Status, and Physiological Status Over Time

● Study
Improved survival and an altered course for cystic fibrosis have led to a need to balance psychosocial and developmental needs in affected children. The authors performed a blinded, randomized controlled trial at four university cystic fibrosis (CF) centers. One hundred and sixteen children were participants in the study over a 9-month period of time. The intervention performed consisted of a home visit to assess each child's knowledge and management of CF. Information was provided using an educational problem-solving approach. Subsequent focus groups were held and the children discussed how to deal with peer issues.

▲ Findings
Children who participated in the intervention group had greater improvements in loneliness, global self-worth, and perceived illness experience. The intervention did not demonstrate an impact upon physical or functional health status but did improve psychosocial status.

■ Nursing Implications
In addition to CF, many chronic and debilitating conditions affect children's quality of life. Any school-age or older child with a chronic condition that impairs physical functioning would benefit from interventions similar to those performed in this study. In particular, nurses who work in settings that allow them to have long-term relationships with these children have the potential to positively influence their lives. Nurses should help children learn communication and problem-solving skills that could lessen the impact of their chronic condition.

Christian, B. J., & D'Auria, J. P. (2006). Building life skills for children with cystic fibrosis: Effectiveness of an intervention. *Nursing Research, 55,* 300–307.

as risk-taking, rebelling, and trying out different identities. Assist the teen with coping and interpersonal skills. Promote involvement in activities with other teens with special needs as well as typical adolescents. Ensure that the teen participates in rites of passage as able, such as attending the prom or obtaining a driver's license. Discuss future plans with the teen, such as college or vocation, as well as transition to an adult health care provider. See Evidence-Based Practice 33.1.

Providing Resources to the Child and Family
Nurses should be familiar with community resources available to children with special health care needs. Educational opportunities for children with special health care needs include early intervention programs and programs offered through the public school system. Financial resources, respite care, and complementary therapies are other areas the nurse should become familiar with.

Educational Opportunities for the Special Needs Child
The foundation for health and development in children is laid during the first years of life. Children with special health care needs often require multiple developmental interventions and special education in the early years in order to reach their developmental potential later in childhood. Children learn best when they are at the stage of maximal readiness, and the early years must not be missed as an opportunity for development. See Healthy People 2010.

Early intervention programs are intended to enhance the development of infants and toddlers with, or at risk for, disabilities, thereby minimizing educational costs and special education. Early intervention is also directed toward enhancing the capacity of families to meet their child's needs as well as to maximize the likelihood of independent living.

The Individuals with Disabilities Education Improvement Act (IDEA) of 2004 (formerly called Public Law 99-457) mandates government-funded care coordination and special education for children up to 3 years of age. This early intervention program is administered through each state. Federal law allows each state to define

HEALTHY PEOPLE 2010

Objective	Nursing Significance
Increase the proportion of children and youth with disabilities who spend at least 80 percent of their time in regular education programs.	Ensure that children under age 3 years who may qualify are referred to the local early intervention program. Encourage families to advocate for their child's needs on the individualized education plan.

"developmental disability" differently, but in general an evaluation of the child's physical, language, emotional, and social capabilities is performed by qualified personnel to determine eligibility. The law guarantees that eligible children will obtain access to services that will enhance their development. Children who qualify for services receive care coordination, and an individualized family service plan is developed by the service coordinator in conjunction with the family. The service coordinator manages the developmental services and special education that the child requires.

The intent of the program is that the child receives services in a "natural environment," so most services occur in the home or daycare center. Home visits by the service coordinator and maintenance of regular contact with the family ensure the success of the program.

Refer children suspected of developmental delay to the local early intervention program. For children receiving these services, collaborate with the service coordinator on an ongoing basis, with particular involvement at hospital discharge and when transition of services occurs at age 3 years.

Think back to Preet, the 2-year-old boy with a history of hydrocephalus and developmental delay, from the beginning of the chapter. Discuss with his mother the educational opportunities that are available for Preet. Explain what early intervention is and why it is important for Preet.

Schools may have a profound impact on the child's overall health and development. Some children with special needs do not require additional services to succeed in school. For these children, the nurse's role is to assess for school success or failure and determine the effect of the school environment on the child's health. The Individuals with Disabilities Education Act, reauthorized in 2004, provides for the education of children with special needs through the public school system, from age 3 to 21 years. These services are provided within the public school system.

According to the law, each special needs student is entitled to an individualized education program (IEP), which is a written plan designed to meet the preschool, primary, or secondary school student's individual needs. A committee consisting of the child's parent, a regular teacher, a special education teacher, and various other specialists develops the IEP. Nurses may be called to serve upon this committee. The IEP must include measurable short- and long-term goals. Parents are informed of the student's progress routinely and the IEP is reviewed at least annually.

Preschool special education through the local public school system is provided from age 3 to 5 years; access to the curriculum is ensured for all children. A child is eligible for special needs preschool when a significant delay is present in the cognitive, language, adaptive, social-emotional, or motor development domains to the extent that it adversely affects the child's learning ability. The child receives (in the school setting) developmental therapy as needed to augment his or her ability to participate in the education process. The least restrictive environment is preferred, with special needs children participating in classes containing age-appropriate typical peers whenever possible. Special needs preschool services are often offered in the elementary school setting.

Financial and Insurance Resources

Many special needs children whose families demonstrate financial need may be eligible for Supplemental Security Income (SSI). This program was created in 1972 through Public Law 92-603. SSI is a cash assistance program, and monthly benefits vary per individual. SSI qualification also qualifies the child for state-administered Medicaid. Medicaid benefits vary slightly from state to state but generally cover medical visits, medication, hospitalization, and limited adjuvant therapies. The State Children's Health Insurance Program (SCHIP) provides low-cost health insurance to eligible children. Eligibility and the extent of benefits provided by SCHIP vary by state.

Public Law 94-566 provides for state-administered Title V programs under the Maternal and Child Health Bureau Block Grant program. State Title V programs provide community-based, comprehensive service coordination for children with special needs (USA.gov, 2007).

Internet Resource for Special Children (www.irsc.org) is an online directory providing a wealth of links to resources for special needs children. Additional online resources include www.childrensdisabilities.info and www.specialchild.com.

Respite Care

Primary caregivers of children with special health care needs must be dedicated, skillful, vigilant, and knowledgeable. Constant care is a stress on the primary caregiver, who needs temporary relief from the daily caregiving demands. **Respite care** provides an opportunity for families to take a break from the daily intensive caregiving responsibilities. Respite care should meet the child's health care needs and offer the child developmental opportunities. Finding and using respite care that the family is comfortable with and trusts may decrease the family's stress and lead to an enhanced quality of life for special needs children and their families. Nurses can facilitate access to respite care, educate respite providers, and ensure quality respite care practices through involvement in community agencies.

Complementary Therapies

Adjuvant therapies are often used by families of children with special health care needs. These may include, among others, homeopathic and herbal medicine, pet therapy,

hippotherapy, music, and massage. Many families desire to blend natural or Eastern medicine with traditional allopathic medicine for their special needs child in search of palliation or a cure. When obtaining the health history, ask specifically about homeopathy or herbal medications the child may be taking.

Pet therapy may be used to decrease stress or as a component of psychotherapy.

Hippotherapy is also referred to as horseback riding for the handicapped, therapeutic horseback riding, or equine-facilitated psychotherapy. Individuals with almost any cognitive, physical, or emotional disability may benefit from therapeutic riding or other supervised interaction with horses. The unique movement of the horse under the child helps the child with physical disabilities to achieve increased flexibility, balance, and muscle strength. Children with mental or emotional disabilities may experience increased self-esteem, confidence, and patience as a result of the unique relationship with the horse. A physical therapist or psychotherapist (depending on the situation) generally works very closely with specially trained equine staff. Box 33.5 lists chronic medical conditions for which hippotherapy may be beneficial. Additional information may be obtained through the North American Riding for the Handicapped Association (www.narha.org) or the American Hippotherapy Association (www.americanhippotherapyassociation.org).

Music may be used to induce positive behavioral changes or various other positive effects (Gasalberti, 2006).

Massage therapy may be beneficial to a wide variety of children. It may be used to reduce pain, promote relaxation, or demonstrate a specific positive effect related to the child's particular medical condition (Gasalberti, 2006).

BOX 33.5 Conditions Benefiting from Hippotheraphy

- Muscular dystrophy
- Cerebral palsy
- Visual impairment
- Down syndrome
- Mental retardation
- Autism
- Multiple sclerosis
- Emotional disabilities
- Brain injury
- Myelomeningocele
- Spinal cord injury
- Amputation
- Attention-deficit disorder
- Learning disabilities
- Deafness
- Cerebrovascular accident (stroke)

▶ *Take* NOTE!

Become familiar with the risks and benefits of homeopathic and herbal medications, as many families use these treatments in an effort to improve their child's quality of life or outcome.

Providing Support and Education

At the time of initial diagnosis, allow and encourage the family to express their feelings. Parents of children with special health care needs require emotional, practical, economic, and social support. Encourage parents to obtain help with daily routines. Encourage stress reduction for the parents through exercise and allowing time for themselves. Be a supportive and encouraging listener, making sure to nurture the whole child, not just his or her special condition (Jackson Allen, 2004).

Parents value peer support groups, sometimes feeling that only other parents of disabled or chronically ill children could understand the heartache, fear, and other emotions they often experience. Pediatric nurses should be proactive in helping families find support systems (Coffey, 2006).

Fathers have the same concerns about their children as mothers do, but they may show this concern differently. It is important for nurses to involve them in the child's care. Teach skills to both parents, and actively involve fathers by asking about their observations and opinions (Ahmann, 2006).

Parents become the experts on their child's needs and care and they should be recognized as such. Parents want to be taken seriously and do not like being ignored (Lindblad et al., 2005). They should be viewed as having reliable and valuable information about their children. By being an active and reflective listener, the nurse can demonstrate to the parents that their opinion is valued, in addition to finding out what the child really needs. Some parents may hesitate to volunteer information, unsure about which information the nurse needs. Show respect for the parents' knowledge of their child's needs by seeking advice on the child's daily care, medical/physical needs, and current developmental level, no matter what the site of care is (Bowie, 2004). See Healthy People 2010.

HEALTHY PEOPLE 2010

Objective	Nursing Significance
(Developmental) Increase the proportion of children with special health care needs who have access to a medical home.	In the primary care setting, build a relationship with the family to establish a medical home. If available, refer families to multidisciplinary programs for medically complex children.

Families may need additional support from the nurse at times of transition (discussed previously). As the equipment or treatment needs change, adjust the teaching plan. Educate the child and family about the use of adaptive equipment. Ensure that families understand how specific activities must be modified to accommodate the child's needs. Provide anticipatory guidance related to expected developmental changes, including resources and laws related to education. Act as a liaison between the family and the daycare center or school. As the child grows and matures, encourage parents to relinquish caregiving tasks to the child as appropriate to encourage independence and promote self-esteem.

Assisting the Adolescent With Special Health Needs Making the Transition to Adulthood

Adolescence is a time of physical changes, psychosocial challenges, and initiation of independence from parents. The adolescent with a chronic illness or one who is technology dependent may experience this period differently than other teens. Puberty is often affected by chronic illness (either delayed or earlier). Chronic illness may lead to isolation from peers at a time when peer interaction is the core of psychosocial development. Teens may struggle to fit in with their peers by hiding their illness or health care needs (ignoring them), complying poorly with treatment regimens, or participating in risky behaviors. At a time when the child should be developing independence from the parents, he or she may be experiencing significant dependence related to the special health condition. Adolescents with chronic health disorders demonstrate mental illness at a rate three to four times higher than normally developing adolescents (Burns et al., 2006). For these reasons, the adolescent with special health care needs may require increased amounts of support from the nurse.

With the tremendous increase in technology and health care, over 85% of all children with chronic illness or special health care needs live into adulthood (Yeo & Sawyer, 2005). Making the transition to adult care for a child with special health care needs can be difficult. A written plan for transition to adult care should be initiated in mid-adolescence. Advance planning leads to a smoother transition to adult care. Have ongoing conversations with the teen about this transition. Issues to be resolved prior to the transition include financial resources for medical care, college or vocational school attendance, living arrangements, and caretaking arrangements.

The Adolescent Health Transition Project (AHTP) recommends the following schedule:

- By age 14, ensure that a transition plan is initiated and that the IEP reflects post–high school plans.
- By age 17, explore health care financing for young adults. If needed, notify the local division of vocational rehabilitation by the autumn before the teen is to graduate from high school of the impending transition. Initiate guardianship procedures if appropriate.
- Notify the teen that all rights transfer to him or her at the age of majority. Check the teen's eligibility for SSI the month the child turns 18. Determine if the child is eligible for SSI work incentives.
- If the youth is attending college, contact the college's campus student disability service program.
- By age 21, ensure that the young adult has registered with the Division of Developmental Disabilities for adult services if applicable.

Prior to moving to adult care (with an adult medical specialist), ensure that the adolescent understands the treatment rationale, symptoms of worsening condition, and especially danger signs. Teach the adolescent about when to seek help from a health professional. Introduce the teen to the medical insurance process. At transition, coordinate a seamless transfer by providing a detailed written plan to the care coordinator or advanced practice nurse (after verbal collaboration).

After the transition, serve as a consultant to the adult office in relation to the teen's needs. Consult with a transition services coordinator or other service agency as available in the local community (AHTP, 2007).

The Dying Child

The idea that a child may die is simply unimaginable to most people, yet children die daily. Each year, about 50,000 children die in the U.S. (Himelstein, 2006), and about 28,000 children who die each year are infants (Mellichamp, 2007). Pediatric nurses will inevitably encounter situations in which a child dies. These situations are extremely difficult for all persons involved, and the nurse plays a key role in caring for the dying child and his or her family.

Grieving

Anticipatory grief may be experienced by the family when the diagnosis of terminal illness is made. Families may deny the prognosis, become angry at the health care system or a higher power, or may experience depression. Acute grief is an intense process that occurs around the time of the actual death. Family members may feel short of breath or as though the throat is tight. They may verbalize that the situation is unreal to them or search for reasons why the death was not prevented. Families may also display hostility or restlessness. Each individual will express grief in his or her own manner. Mourning the death of a loved one takes a long time, and families should be supported throughout the process.

Palliative Care of the Dying Child

Appropriate **palliative care** is essential for any child with a life-threatening or progressive incurable condition. Whether palliative care is provided in the home, hospital,

or hospice setting, the goal is to provide the best quality of life possible at the end of life while alleviating physical, psychological, emotional, and spiritual suffering. The Last Acts Palliative Care Task Force has established principles on which palliative care of children should be based. These include:

- Respecting patients' goals, preferences, and choices
- Comprehensive caring
- Using the strengths of interdisciplinary resources
- Acknowledging and addressing caregivers' concerns
- Building systems and mechanisms of support (Association of Pediatric Oncology Nurses, 2003)

Hospice Care

Hospice allows for family-centered care in the child's home or a hospice facility. As with adult hospice care, the comfort of the entire family is important. The goals of pediatric hospice care are enhancement of quality of life for the child and family through an individualized plan of care (Children's Hospice International, 2007). The recommended standards for pediatric hospice care do not preclude involvement in ongoing treatment (this is in contrast to adult hospice), but certain eligibility criteria must be met. Parents are educated on ways to comfort and interact with their dying child, such as massage, movement, or singing. Spiritual support is available through a chaplain, social worker, or the family's minister. The nurse not only educates the family about the dying process but also assists them with providing basic care and pain management. The decision to withhold nutrition or hydration may be made in certain instances. Pain management is of utmost importance for the terminally ill child. Ongoing bereavement care is also provided to the family by the hospice after the child's death.

Nursing Management of the Dying Child

Though interdisciplinary care is essential for quality care at the end of life, it is the nurse who plays the key role of child/family advocate and who is usually the constant presence throughout the dying process. Nursing management of the dying child focuses on end-of-life decision making, meeting the child's and family's needs, and assisting the family after the child's death. Throughout the process, focus on the family as the unit of care (Malloy et al., 2006).

Assisting the Family With End-of-Life Decision Making

Parents are obligated not only to protect their children from harm but also to do as much good for them as possible, both from an ethical and legal standpoint (Rushton, 2004). When the time comes for end-of-life decision making, parents are often torn about the "right" course of action. Parents may be asked to make decisions about stopping treatment, withdrawing treatment, providing palliative care, or consenting to do not resuscitate (DNR) orders. Patients, parents, and health care providers are generally in agreement that continued suffering is not desired for any child with a terminal illness. When all possible curative attempts have been made, then survival is no longer possible.

Nurses involved in this process must examine their own values related to dying and consider the American Nurses Association's code of ethics for nurses as well. The family's feelings must also be acknowledged. During the process of end-of-life decision making, health care providers must assure families that the focus of care is changing and that the child is not being abandoned (Rushton, 2004). Emphasize to parents that no matter what their decision is, the health care team is dedicated to the comfort and expert care of their child.

Ensure that communication is family-centered. Quality of life must be taken into consideration when making decisions to continue or withhold treatment (Jacobs, 2005). Provide parents facing end-of-life decisions with honest information and education from the time of the diagnosis/prognosis forward. Anticipate that parents may vacillate in the decision-making process. Clarify information for them and allow them private time to discuss the options. Do not make judgments about or question the parents' decision. Be sensitive to any ethnic, spiritual, or cultural preferences during the terminal stage of the illness. Encourage parents to interact with other parents who have a child with a terminal illness.

Allowing Natural Death

The decision to institute a DNR order is one of the most difficult decisions a family may ever have to make. DNR refers to withholding cardiopulmonary resuscitation should the child's heart stop beating. Parents may initially feel like this means they are giving up on their child. Nurses must educate families that resuscitation may be inappropriate and lead to more suffering than if death were allowed to occur naturally. The parents need to understand that when a palliative care route is chosen, rather than continuing a curative or treatment route, the focus of the child's care is changing but that the child and family are not being abandoned. Families may wish to specify a certain extent of resuscitation that they feel more comfortable with (e.g., allowing supplemental oxygen but not providing chest compressions). Some institutions are now replacing the DNR terminology with "allow natural death" (AND), which may be more acceptable to families facing the decision to withhold resuscitation (Knox & Lenehan, 2005).

Involving the Dying Child in the Decision-Making Process

End-of-life decision making often involves ethical dilemmas for the patient, family, and health care team. This is particularly true when the parents' wishes conflict with the child's or adolescent's desires. Children should be

involved in decision making to the extent that they are able. Discuss intervention within the context of the child's condition and wishes. Children over the age of 7 may "assent" to the continuation or withdrawal of treatment (Kon, 2006). Be available to the older child or adolescent to provide support and information if he or she desires. Talk with the child or adolescent with the parents present, as well as in private. Maintain the child's comfort and dignity. Encourage the child to spend time with other children with a terminal illness. Assure the child that everything will be done to make him or her comfortable.

Consult parents about the timing and depth of end-of-life discussions. Just as parents do, the terminally ill child may vacillate in the decision-making process. Remain sensitive, and respect the child's decisions.

Organ or Tissue Donation

With large numbers of organ transplant candidates on waiting lists and the shortage of viable organs, pediatric organ and tissue donation is a priority. For many families, knowing that a child's organs or tissues may save another child's life provides a way to help others despite their own loss. A healthy child who dies unexpectedly is an excellent candidate for organ donation. Many chronic illnesses in children preclude the option of organ or tissue donation, though individual determinations of eligibility should be made.

The discussion of organ donation should be separated from the discussion of impending death or brain death notification. Written consent is necessary for organ donation, so the family must be appropriately informed and educated. Many families who never thought about it before may consider the option of donation if adequately educated about the process. All expenses for organ procurement are borne by the recipient's family, not the donor's. Ask whether the dying child ever expressed a wish to donate organs and whether the parents have considered it.

Families need to know that procurement of the organs does not mar the child's appearance, so that an open casket at the child's funeral is still possible if the family desires. The donating child will not suffer further because of organ donation. The organs or tissues will be harvested in a timely fashion after the declaration of death, so the family need not worry about delay of the wake or funeral. The family's cultural and religious beliefs must be considered, and the team discussing organ donation with the family must do so in a sensitive and ethical manner.

Managing Pain and Discomfort

Pain management is an essential component of care for the child with a terminal illness. Providing for comfort enhances the child's quality of life and minimizes suffering. Assess pain using a developmentally appropriate tool (see Chapter 35 for further information). Provide pain medication around the clock rather than on an "as needed" basis to prevent recurrence or escalation of pain. Determine the child's preferred comfort measures and use them to provide additional relief. Change the child's position frequently but gently to minimize discomfort. Limit nursing care to comfort measures that ease the child's discomfort. Maintain a calm environment, minimizing noise and light.

Easing Anxiety or Fears

Involve the parents and other family members in all phases of the child's care. Explain all aspects of care to the child to minimize anxiety related to nursing interventions. Answer the child's questions honestly. Involve the child in decision making whenever possible. Limit interventions to those related to palliation, rather than treatment, advocating for the child as needed. Remain with the child when a parent or family member is not in the room so the child will not fear dying alone.

Providing Nutrition

Since the body naturally requires less nutrition as the child is dying, do not excessively coax the child to eat or drink. Offer frequent small meals or snacks of the child's choosing. Soups and shakes require less energy to eat and so may be desirable. If the child desires a different food, provide that one. Keep strong odors away from the child to decrease nausea. Administer antiemetics as needed. Provide mouth care and keep the lips lubricated to keep the mouth feeling clean and prevent the discomfort associated with chapped lips. Make sure the environment is a pleasant one for eating.

Supporting the Dying Child and Family

To foster a holistic connection with the child and family, be attuned to the entire family's needs and emotions. Nurses provide physical care through specific tasks and interventions for the dying child, but they also need to be fully present with the child and family. In general, people are uncomfortable with the concept of a dying child. Nurses should work through their own feelings about the situation to be able to be "in the moment" with the child and family. Ask yourself: Can I be fully present with this family? If not, then what can I change to be so?

Families and dying children benefit from the presence of the nurse, not just the interventions he or she performs. Families report that the simple of act of being present with the family is very healing (Mellichamp, 2007). Listen to the child and family; be still and silent for a time to accomplish this. Foster respect for the whole child by attending to him or her as such.

Respect the parents of the dying child by helping them honor the commitments they have made to their child. Acknowledge that parents have diverse needs for information and participation in decision making. Allow and encourage family customs or rituals in relation to death and dying. Families may desire the pastor or priest to be present when the child's death is imminent. Certain rituals may be desired, depending on the family's religious or spiritual background. Ensure that these important events occur, and alter nursing care routines as needed to accom-

modate them. Respect the family's need to participate in these rituals and customs.

Work collaboratively with the family and health care team to provide for the needs of the child and family (Rushton, 2005). Resources for families of a dying child are listed in Box 33.6. The Make-a-Wish Foundation (www.wish.org) works to grant the wishes of terminally ill children, giving the child and family an experience of hope, strength, and love.

Meeting the Dying Child's Needs According to Developmental Stage

It is important to provide the type of support and education that the dying child needs according to his or her developmental stage. For the infant, unconditional love and trust are of utmost importance. Ensure that the infant's family is available to the child. The toddler, 1 to 3 years old, thrives on familiarity and routine. Maximize the toddler's time with parents, be consistent, provide favorite toys, and ensure physical comfort. Spirituality in the preschool years focuses on the concept of right versus wrong. The 3- to 5-year-old may see death as punishment for wrongdoing; correct this misunderstanding. Use honest and precise language. Help the parents to teach the child that though the family will miss the child, it will continue to function without him or her.

The school-age child has a concrete understanding of death. Children who are 5 to 10 years old need specific, honest details (as desired). Encourage the child to help make decisions, and help the child to establish a sense of control.

The young adolescent (10 to 14 years old) will benefit from reinforcement of self-esteem, self-respect, and a sense of worth. Respect the child's need for privacy and time alone as well as time requested with peers. Support the need for independence and encourage the child to participate in decision making. The older teen (14 to 18 years of age) has a more adult-like understanding of death and will need further support through honest, detailed explanations and will want to feel truly involved and listened to.

Key Concepts

- Children with special health care needs are those who have, or are at risk for, a chronic physical, developmental, behavioral, or emotional condition that generally requires more intensive and diverse health services, as well as coordination of those services, than do typical children.
- Most children with chronic illnesses or who are dependent on technology progress through stages of growth and development just as typical children do, though possibly at a slower pace, and desire to be treated as normal children.
- Parents of special needs children experience a multitude of emotions and changes in their lives, often carrying a heavy caregiving burden. They become the experts on their child's care and should be empowered and supported in their efforts.
- Children with special health care needs are at increased risk for the development of vulnerable child syndrome, which may have psychologically harmful effects on the child and parents for many years.
- Home is the most developmentally appropriate environment for children with special health care needs and those who are technology dependent. Children display an improved physical, emotional, psychological, and social status when they are cared for at home.
- Family-centered care provides the optimal framework for caring for children and families with special needs. Empowering the family strengthens them. A medical home or permanent relationship with the health care provider benefits the family, as care coordination and advocacy are provided.
- Use adjusted (or corrected) age when assessing growth and development of the infant or child who was born prematurely. Provide early screening and intervention for issues related to development to maximize the former preemie's potential for growth and development.
- Become familiar with the risks and benefits of adjuvant therapies used by some families of children with special health care needs.

- Screen children with special health care needs for failure to thrive or a feeding disorder.
- Screening helps to identify children with unmet health needs early so that intervention may begin.
- The child and family with special needs may require additional support during times of transition, such as at initial diagnosis or change in prognosis, when symptoms increase, when the child moves to new setting (hospital, school), during periods of developmental change, or during a parent's absence.
- Early discharge planning and ongoing inclusion and education of the family facilitate continuity of care. During mid-adolescence, initiate a written plan to help the special needs child make the transition to adult care.
- Early intervention provides care coordination (developmental services and special education), as well as an individualized family service plan for qualifying children and their families.
- Each special needs student is entitled to an individualized education program (IEP), which is a written plan that is designed to meet the preschool, primary, or secondary school student's needs.
- Younger children who are dying generally need for their families to be close and to trust their needs will be provided for. Older children require honest explanations given at a level appropriate for the child's age or developmental stage.
- Support the dying child and the family throughout the end-of-life decision-making process, providing facts as desired about palliative care, hospice, and organ donation.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. The parents of a 5-year-old with special health care needs talk to the parents of a 10-year-old with a similar condition for quite a while each day. What is the nurse's interpretation of this behavior?
   a. The nurse has not provided enough emotional support for the parents.
   b. This relationship between the children's parents is potentially unhealthy.
   c. Support between parents of special children is extremely valuable.
   d. Confidentiality is a pressing issue in this particular situation.
2. The nurse is caring for a child who has received all possible medical care for cancer, yet continues to experience relapse and metastasis. It is time to make the transition from curative care attempts to palliative care. What is the most important nursing consideration at this time?
   a. The health care professionals should make the decision about the child's care.
   b. The family may lose a sense of hope, so cancer treatments should continue.
   c. Involve the family in the decision-making process about the shift to palliative care.
   d. Palliative care can take place only at home, so the child should be discharged.
3. The nurse is caring for a 3-year-old with a gastrostomy tube and tracheostomy who is on supplemental oxygen and multiple medications. The mother is rooming in during this hospitalization. What is the priority nursing action?
   a. Incorporate the mother's assistance in care when convenient.
   b. Recognize the mother as the expert on her child's needs and care.
   c. Recommend that the mother go home to get some rest.
   d. Provide family-centered care since the mother is there.
4. The nurse is caring for a child with a developmental disability who is starting kindergarten this year. The mother is tearful and doesn't want the child to go to school. What is the best response by the nurse?
   a. "Do you need some time alone to collect yourself?"
   b. "You've known for a while this time would come."
   c. "Can I call your husband or a friend for you?"
   d. "It is normal to feel stressed or sad at this time."
5. The parents of a child with a developmental disability ask the nurse for advice about disciplining their child. What is the best response by the nurse?
   a. "You should choose methods that are most congruent with your values about discipline."
   b. "Children like this really can't follow directions, so they may be very hard to discipline."
   c. "Punish your child only for socially unacceptable or offending behaviors."
   d. "Spanking works well for this type of child, as they really don't like pain."

CRITICAL THINKING EXERCISES

1. A 15-year-old boy is dying of cancer after all medical care options have been exhausted. Describe the plan of care for this child and his family. What strategies should the nurse use to support the child and his family through this difficult process?
2. A 5-month-old infant who was born at 24 weeks' gestation is ready to be discharged from the NICU. She will be going home on oxygen, gastrostomy tube feedings, and eight medications. Develop a teaching plan for the family.

STUDY ACTIVITIES

1. In the clinical setting, care for a child with a terminal illness. Reflect in your clinical journal about the feelings you had during the care of the child, as well as the feelings and behaviors that you noticed in the child, siblings, parents, and nursing staff.
2. Visit a preschool that provides care for developmentally delayed and typical children. Choose two same-age children, one with a disability or impairment and the other a typical healthy child. Perform a Denver developmental screening or development assessment on each of the two children. Compare and contrast your findings.
3. Spend the day with a home care nurse providing care for a technology-dependent child. What obstacles has the family overcome to have this child at home? What adjustments does the nurse make to provide family-centered care in the home (as compared to the hospital setting)?

CHAPTER 34

Medication Administration, Intravenous Therapy, and Nutritional Support

KEY TERMS

biotransformation
bolus feeding
enteral nutrition
gastrostomy
gavage feedings
infiltration
parenteral nutrition
pharmacodynamics
pharmacokinetics
residual
total parenteral nutrition

LEARNING OBJECTIVES

Upon completion of this chapter, the learner will be able to:

1. Describe atraumatic methods for preparing children for procedures.
2. Describe the "eight rights" of pediatric medication administration.
3. Explain the physiologic differences in children affecting a medication's pharmacodynamic and pharmacokinetic properties.
4. Accurately determine recommended pediatric medication doses.
5. Demonstrate the proper technique for administering medication to children via the oral, rectal, ophthalmic, otic, intravenous, intramuscular, and subcutaneous routes.
6. Integrate the concepts of atraumatic care in medication administration for children.
7. Identify the preferred sites for peripheral and central intravenous medication administration.
8. Describe nursing management related to maintenance of intravenous infusions in children, as well as prevention of complications.
9. Explain nursing care related to enteral tube feedings.
10. Describe nursing management of the child receiving total parenteral nutrition.

Lily Kline, a 9-month-old, is admitted to your unit for failure to thrive. The physician has ordered insertion of a nasogastric tube to begin gavage feedings. The parents are very nervous and upset about this. They ask, "What will this tube do for Lily? It sounds very uncomfortable. What do you have to do to insert it? Will it have to stay in all the time? Won't it move?" How would you address their concerns?

Wow

Quality technical skills delivered by a caring hand are a vital part of good nursing care

The ill child often requires medications, intravenous (IV) therapy, or enteral nutrition to restore health. These procedures occur most often in the inpatient setting, but with today's advanced technology many children may receive treatment in the home, daycare center, school, physician's office, or other community setting.

This chapter begins with an overview of the important aspects of caring for a child who is to undergo a procedure. The key elements of and guidelines for care related to medication administration, IV therapy, and nutritional support in children will be discussed. Child and parent education is emphasized. The chapter will focus on adapting and modifying nursing procedures based on the child's growth and development and providing these treatments using a family-centered, atraumatic approach.

Children and Procedures

Children undergo numerous diagnostic and therapeutic procedures in a wide range of settings during their development. Medication administration, IV therapy, and nutritional support are just three examples. These procedures may be performed in the community or outpatient setting or in a care facility. Regardless of the procedure to be performed and the setting, children, like adults, need thorough preparation before the procedure and support during and after the procedure to promote the best outcome.

Before the Procedure

Appropriate preparation for procedures helps to decrease the child's and family's anxiety level, promote the child's cooperation, and support the child's and family's coping skills. Adequate preparation also helps to foster the child's feeling of mastery over a potentially stressful event, as undergoing invasive procedures in particular is extremely distressing for children.

Preparation may include psychological preparation (including explanation and education) as well as preparing the child physically. Employ the concept of atraumatic care when preparing children for a procedure. General guidelines for preparation include the following:

- Provide a description of and the reason for the procedure using age-appropriate language ("the doctor will look at your blood to see why you are sick").
- Describe where the procedure will occur ("the x-ray department has big machines that won't hurt you; it's a little cold there too").
- Introduce strange equipment the child may see ("you will lie on a special bed that moves in the big machine, but you can still see out").
- Describe how long the procedure will last ("you will be in the x-ray department until lunchtime").
- Identify unusual sensations that may occur during the procedure ("you may smell something different" [e.g., alcohol smell], "the MRI machine makes loud noises").
- Inform the child if any pain is involved.
- Identify any special care required after the procedure ("you will need to lie quietly for 15 minutes afterward").

▶ *Take* NOTE!

In the hospital, perform all invasive procedures in the treatment room or a room other than the child's room. The child's room should remain a safe and secure area.

A major aspect of preparation involves play. In general, young children respond better to play materials and older children benefit more from viewing peer modeling films. However, consider the child's temperament, coping strategies, and previous experiences as well as developmental needs and cognitive abilities. First, gain trust and provide support. Include the child's parents, because parents are usually the greatest source of comfort for the child. Be short, simple, and appropriate in explaining situations at the child's level of development. Explain what is to be done and what is expected of the child. Avoid terms that have double meanings or might be confusing. Table 34.1 lists alternative words or phrases to use for terms that may be confusing or misunderstood.

During the Procedure

Use a firm, positive, confident approach that provides the child with a sense of security. Encourage cooperation by involving the child in decision making and allowing the child to select from a list or group of appropriate choices. Allow the child to express feelings of anger, anxiety, fear, frustration, or any other emotions. Often this is how a child communicates and copes with the situation. Tell the child that it is okay to scream or cry, but that it is very important to hold still. Use distraction methods such as those listed in Box 34.1.

Toddlers and preschoolers often resist procedures despite preparation for them. Being held down or restrained is often more traumatizing to the young child than the procedure itself. Use alternative methods (positions that provide comfort for the child) to keep the child still during the procedure (Fig. 34.1). The older child can be held while using a book or story for distraction.

After the Procedure

After the procedure, hold and comfort the child. Cuddle and soothe infants. Encourage children to express their feelings through play, such as dramatic play or use of puppets. Gross motor activities such as pounding or throwing are also helpful for children to discharge pent-up feelings and energy. School-age children and adolescents may not outwardly demonstrate behavior indicating the need for

TABLE 34.1 ALTERNATIVES FOR CONFUSING OR MISUNDERSTOOD TERMS

Term to Avoid	How Children Might Interpret It	Use These Terms Instead
Catheter	Too technical	Tube
Deaden	Kill?	Make sleepy
Dye	"Die"	Special medicine to help the doctor see _____ (part of the body) better
Electrodes	Too technical	Stickers, ticklers, snaps
ICU	"I see you"	Special room with your own nurse
Incision, cut open, make a hole	Too explicit	Special or small opening
Monitor	Too technical	TV screen
Organ	Like a piano?	Special place in the body
Pain	May be too explicit	Child's word for hurt; "boo-boo"
Put to sleep, anesthesia	May confuse with putting a pet to sleep	Special kind of sleep
Shot	Children are scared of shots	Medication under the skin
Stool	Like you sit on?	"Poop" or child's word for it
Stretcher or gurney	"Stretch her"	Rolling bed or special bed on wheels
Take your temperature/BP	Where are you going to "take" them?	See how warm you are/hug your arm
Test	Like at school? (the child will need to perform)	See how your heart is working
Tourniquet	Too technical	Special kind of rubber band
Urine	"You're in?"	"Pee" or child's word for it
X-ray	Don't understand	Picture or big camera to take pictures of the inside of your body

Partially adapted from Florida Children's Hospital, *Suggested vocabulary to use with children.*

comforting; however, provide them with opportunities to express their feelings and be comforted. Remember to praise children for appropriate behavior during the procedure and after all interventions are completed.

Medication Administration

WATCH & LEARN

At one time or another, every child will need to receive medication. As with adults, pediatric medication administration is a critical component of safe and effective nursing care. However, the incidence of potentially harmful medication errors may be three times as high in pediatrics compared to adults (Ghaleb et al., 2006). Therefore, the need for safety takes on even greater importance due to the physiologic, psychological, and cognitive differences inherent in children. The pediatric nurse must adapt administration principles and techniques to meet the child's needs. Medication administration, regardless of the route, requires a solid knowledge base about the drug and its action.

As with medication administration to any patient, the nurse must adhere to the "rights" of medication administration (Box 34.2). Confirming the child's identity and double-checking the dosage before administration of any medication are two critical safeguards that play a major role in preventing medication errors.

BOX 34.1 Distraction Methods

- Have the child point toes inward and wiggle them.
- Ask the child to squeeze your hand.
- Encourage the child to count aloud.
- Sing a song and have the child sing along.
- Point out the pictures on the ceiling.
- Have the child blow bubbles.
- Play music appealing to the child.

▶ *Take* NOTE!

If a parent, caregiver, or patient questions whether a medication should be given, listen attentively, answer their questions, and double check the order.

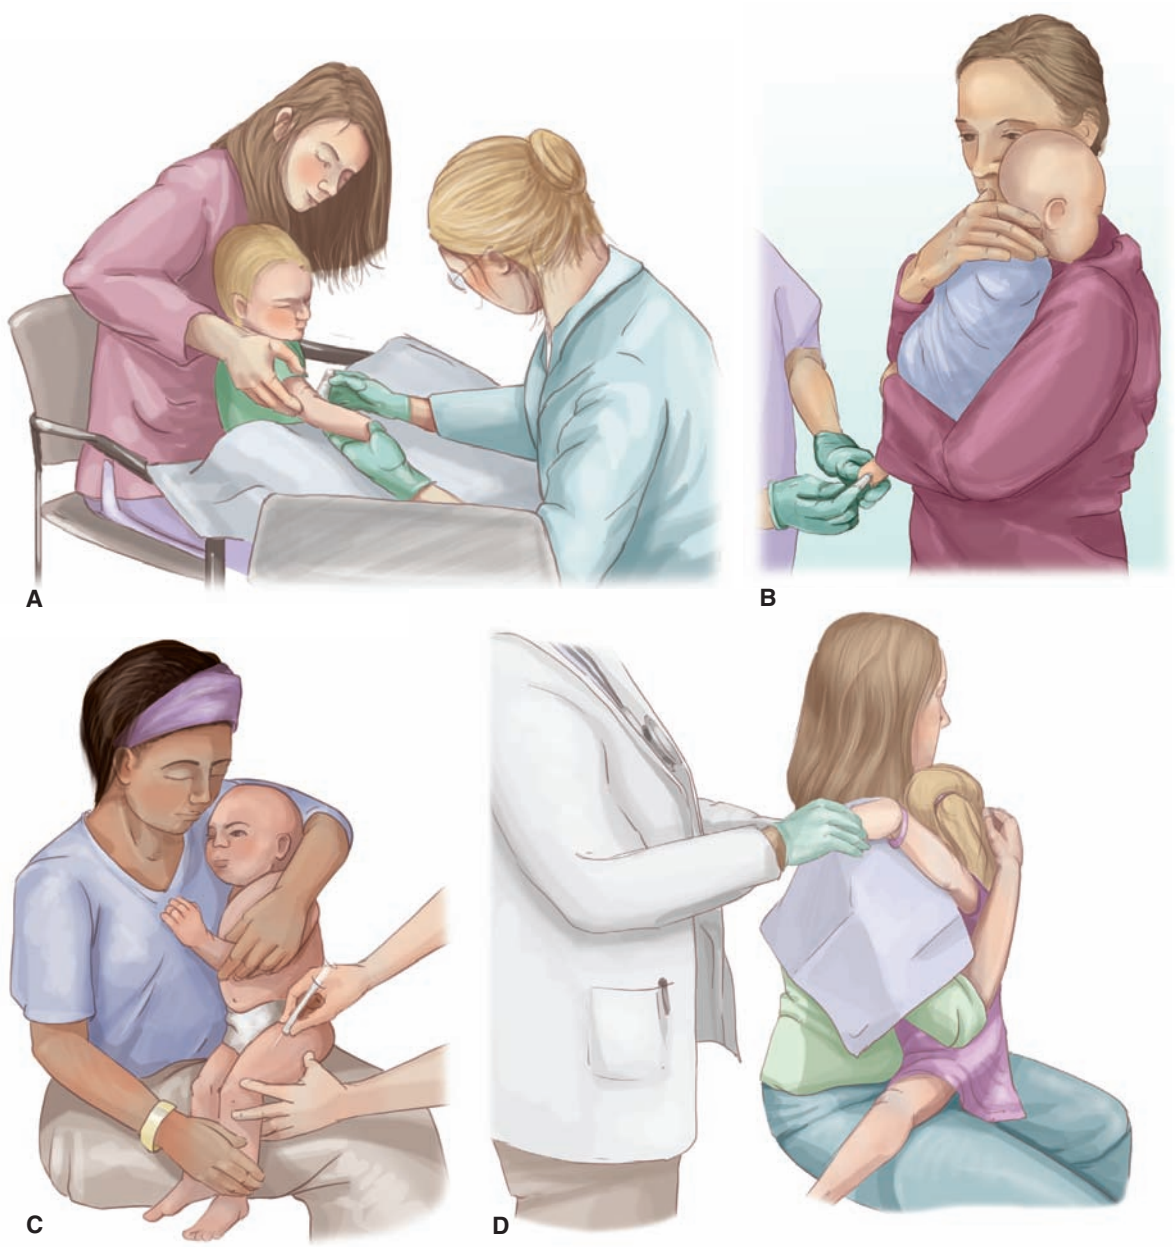

FIGURE 34.1 Positioning a child for comfort during a painful procedure. (**A**) Sitting on the parent's lap while undergoing allergy testing provides this toddler with a sense of comfort. (**B**) Position the infant cuddled over the parent's (preferable) or the nurse's shoulder when obtaining a heelstick. (**C**) Use "therapeutic hugging" to maintain a child's position when the child is receiving an IM injection. (**D**) Use "therapeutic hugging" to position a child while the child is having an IV line inserted.

Differences in Pharmacodynamics and Pharmacokinetics

Although a drug's mechanism of action is the same in any individual, the physiologic immaturity of some body systems in a child can affect a drug's **pharmacodynamics** (behavior of the medication at the cellular level). As a result, the body may not respond to the drug as intended. The intended effect may be enhanced or diminished, necessitating a change in the dosage to ensure optimal effectiveness without increasing the child's risk for toxicity.

The child's age, weight, body surface area, and body composition also can affect the drug's **pharmacokinetics** (movement of drugs throughout the body via absorption, distribution, metabolism, and excretion). Drugs are administered to children via many of the same routes that are used for adults. However, this similarity ends once the drug is administered.

During the absorption process, drugs move from the administration site into the bloodstream. In infants and young children, the absorption of orally administered medications is affected by slower gastric emptying, increased

BOX 34.2 Eight Rights of Pediatric Medication Administration

Right Medication
- Check order and expiration dates.
- Know action of medication and potential side effects (use pharmacy, drug formulary).
- Ensure that the medication provided is the medication that is ordered.

Right Patient
- Confirm patient identity since children may deny their identity in attempt to avoid an unpleasant situation, play in another child's bed, or remove ID bracelet.
- Confirm identity each time medication is given.
- Verify child's name with caregiver to provide additional verification.

Right Time
- Give within 20 to 30 minutes of the ordered time.
- For a medication given on an as-needed (PRN) basis, know when it was last given and how much was given during the past 24 hours.

Right Route of Administration
- Check ordered route and ensure this is the most effective and safe route for this child; clarify any order that is confusing or unclear.
- Give the medication by the route ordered. If there is a need to change route, always check with prescriber (e.g., if a child is vomiting and has an order for an oral medication, the medication may need to be given via the IV or rectal route).

Right Dose
- Calculate the recommended dose according to child's weight and double-check your calculations.
- Always question the pharmacist and/or prescriber if the ordered dose falls outside the recommended dose range.
- Unusually large or small volumes or dosages should always be verified.

Right Documentation
- Record administration of the medication on the appropriate paper or computerized form according to agency policy.
- Ensure that all medications administered and refused are documented.

Right to Be Educated
- Provide simple explanations to the child based on his or her level of understanding.
- Explain to the parents or caregiver about the medication to be given and what to expect from it.
- Use a positive, firm approach with the child.

Right to Refuse
- Provide explanations to the child and parents to clarify any misconceptions or relieve fears.
- Reinforce the rationale for medication use.
- Respect the child's or parents' option to refuse.

intestinal motility, a proportionately larger small intestine surface area, higher gastric pH, and decreased lipase and amylase secretion compared with adults. Intramuscular absorption in infants and young children is affected by amount of muscle mass, muscle tone and perfusion, as well as vasomotor instability. Similarly, decreased perfusion alters subcutaneous absorption. Absorption by these routes is erratic and may be decreased. In contrast, topical absorption of medications is increased in infants and young children because the stratum corneum is thinner and well hydrated (Lilley et al., 2005; Woo, 2004).

The distribution (movement of a drug from the blood to interstitial spaces and then into cells) of medications is also altered in infants and young children. Medication distribution in children is affected by:

- Higher percentage of body water than adults
- More rapid extracellular fluid exchange
- Decreased body fat
- Liver immaturity, altering first-pass elimination
- Decreased amounts of plasma proteins available for drug binding
- Immature blood–brain barrier, allowing permeation by certain medications (Lilley et al., 2005; Pickar, 2004; Woo, 2004)

Metabolism of medications in children is altered because of differences in hepatic enzyme production and the child's increased metabolic rate. **Biotransformation** (the alteration of chemical structures from their original form, which allows for the eventual excretion of the substance) is affected by the same variations affecting distribution in children. In addition, the immaturity of the kidneys until the age of 1 to 2 years affects renal blood flow, glomerular filtration, and active tubular secretion. This results in a longer half-life and increases the potential for toxicity of drugs primarily excreted by the kidneys (Lilley et al., 2005; Woo, 2004).

Developmental Issues and Concerns

Children are constantly growing and developing. The specific psychosocial, cognitive, physical, and motor developmental levels of children are important. Nurses need a solid understanding of growth and development to ensure safe administration of medications to children. Table 34.2 details some growth and development issues related to administering medications to children. Always give developmentally appropriate, truthful explanations before administering medications to children. Include why the drug is needed, what the child will experience,

TABLE 34.2 GROWTH AND DEVELOPMENT ISSUES RELATED TO PEDIATRIC MEDICATION ADMINISTRATION

Stage of Development	Issue/Concern	Nursing Interventions
Infant	Development of trust, which is fostered by consistent care; development of stranger anxiety later in infancy	Involve parents in medication administration to reduce stress for infant. Ensure that parents hold and comfort infant during intervention.
Toddler	Development of autonomy with displays of negativism; rituals, routines, and choices necessary to maintain some sense of control	Follow routines and rituals from home in giving medications if these are safe and positive approaches. Involve parents in medication administration. Offer simple choices (e.g., "Do you want Mom or me to give you your medicine?"). Allow child to touch or handle equipment as appropriate.
Preschooler	Development of initiative, which is fostered when they sense they are helping	Provide an opportunity to play with the equipment and respond positively to explanations and comforting. Provide choices that are possible and keep them simple (e.g., "Do you want juice or water with your medication?" or "Which medication do you want to take first?"). Do not ask, "Will you take your medicine now?" Involve parents in medication administration. Be aware that giving suppositories is particularly upsetting to this age group because of their fears of bodily intrusion and mutilation.
School-aged child	Development of industry, benefiting from being a part of their care; generally very cooperative	Explain to child in simple terms the purpose of the medication. Seek their assistance, such as putting pills in cup or opening the packet, and allow a broader range of choices. Establish a reward system to enhance their cooperation if necessary.
Adolescent	Development of identity, benefiting from much more control over their care	Approach in same manner as adults, with respect and sensitivity to their needs. Maintain the adolescent's privacy as much as possible.

what is expected of the child, and how the parents can participate and support their child. Refer to Chapters 25 through 29 for further information about growth and developmental issues.

The child's past experiences with taking medications and the approaches that may have been used will often affect how the child reacts. Always approach children positively; let your manner convey the belief that they can accomplish this needed behavior. Never label the child as "bad" if he or she did not fully cooperate in taking medication. When medications must be administered with a needle (intramuscularly or subcutaneously), assure the child that this method is not a consequence of the child's behavior. Help parents to work through the feelings of frustration that may result from the child's refusal to cooperate with medication administration. Provide parents with facts about growth and developmental issues and children's fears and anxiety related to medication administration. Model alternative ways for the parents to deal with undesirable behavior.

▶ ***Take*** NOTE!

Always administer medications promptly, assist the child in holding still using a comforting position for the child, and reward positive behavior.

Determination of Correct Dose

Administering the correct dose is a key component of medication administration. Incorrect dosing is the most commonly reported medication error in the pediatric population (Ghaleb et al., 2006). Many drug references list recommended pediatric dosages, and nurses are responsible for checking doses to ensure that they are appropriate for the child. Two common methods for determining pediatric doses are based on the unit of drug per kilogram of body weight or body surface area (BSA).

Dose Determination by Body Weight

The most common method for calculating pediatric medication doses is based on body weight. The recommended dosage is usually expressed as the amount of drug to be given over a 24-hour period (mg/kg/day) or as a single dose (mg/kg/dose). Differentiate between the 24-hour dosage and the single dose. Use these guidelines to determine the correct dose by body weight:

1. Weigh the child.
2. If the child's weight is in pounds, convert it to kilograms (divide the child's weight in pounds by 2.2).
3. Check a drug reference for the safe dose range (for example, 10 to 20 mg/kg of body weight).
4. Calculate the low safe dose (Box 34.3).
5. Calculate the high safe dose.
6. Determine if the dose ordered is within this range.

BOX 34.3 Dosage Calculation Using Body Weight

After converting the child's weight in pounds to kilograms and checking the safe dose range:

- Calculate the low safe dose range (e.g., 10 to 20 mg/kg and the child weighs 30 kg):
  - Set up a proportion using the low safe dose range
    10 mg/1 kg = x mg/30 kg
  - Solve for x by cross-multiplying:
    $1 \times x = 10 \times 30$
    $x = 300$ mg
- Calculate the high safe dose range:
  - Set up a proportion using the high safe dose range
    20 mg/1 kg = x mg/30 kg
  - Solve for x by cross-multiplying:
    $1 \times x = 20 \times 30$
    $x = 600$
- Compare the safe dose range (for this example, 300 to 600 mg) with the ordered dose. If the dose falls within the range, the dose is safe. If the dose falls outside the range, notify the prescriber.

The pediatric dosage should not exceed the minimum recommended adult dosage. Generally, once a child or adolescent weighs 50 kg or greater, the adult dose is frequently prescribed. However, always verify that the dose does not exceed the recommended adult dose (Pickar, 2004).

Dose Determination by Body Surface Area

Calculating the dosage based on BSA takes into account the child's metabolic rate and growth. It is commonly used for chemotherapeutic agents. Some recommended medication doses may read "mg/BSA/dose." To determine the dose using BSA, you will need to know the child's height and weight, which will be plotted on a nomogram (Fig. 34.2). A nomogram is a graph divided into three columns: height (left column), surface area (middle column), and weight (right column). Use these guidelines to determine BSA:

1. Measure the child's height.
2. Determine the child's weight.
3. Using the nomogram, draw a line to connect the height measurement in the left column and the weight measurement in the right column.
4. Determine the point where this line intersects the line in the surface area column. This is the BSA, expressed in meters squared (m^2).

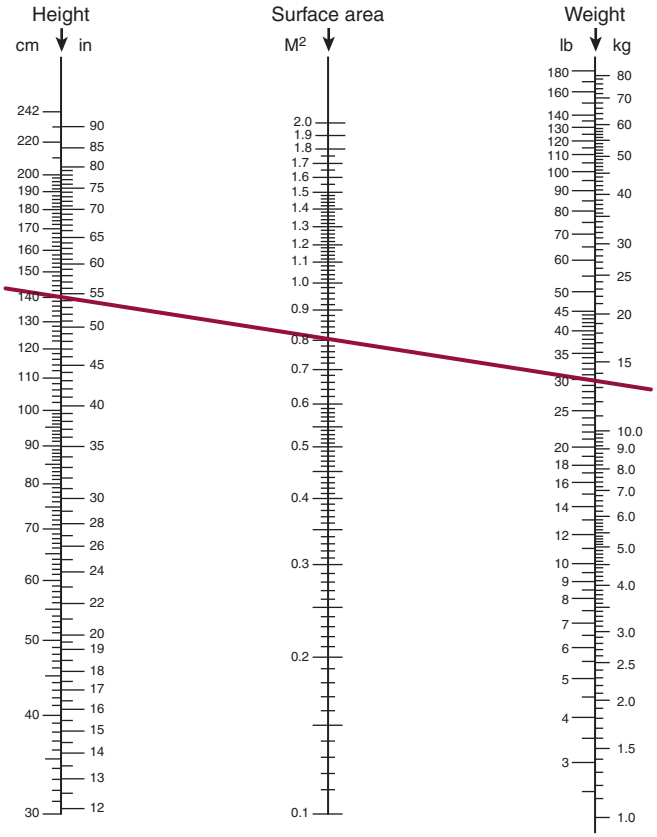

FIGURE 34.2 A nomogram to determine body surface area.

Once you have determined the BSA, use the recommended dosage range to calculate the safe dosage.

Oral Administration

Medications to be given via the oral route are supplied in many forms, such as liquids (elixirs, syrups, or suspensions), powders, tablets, and capsules. Generally, children under the age of 5 to 6 are at risk for aspiration because they have difficulty swallowing tablets or capsules. Therefore, if a tablet or capsule is the only oral form available, it needs to be crushed or opened and mixed with a pleasant-tasting liquid or a small amount (generally no more than a tablespoon) of a nonessential food such as applesauce. However, never crush or open an enteric-coated or time-release tablet or capsule. The crushed tablet or inside of a capsule may taste bitter, so never mix it with formula or other essential foods. Otherwise, the child may associate the bitter taste with the food and later refuse to eat it.

▶ *Take* NOTE!

Certain drug formulations should not be crushed. Before crushing a pill or opening a capsule, always check that this will not alter the intended effects of the drug.

Liquid medications, primarily suspensions, may be less concentrated at the top of the bottle than at the bottom of the bottle. Always shake the liquid to ensure even drug distribution. The key to administering liquid forms of oral medications is to use calibrated equipment such as a medicine cup, spoon, plastic oral syringe, or dropper (Fig. 34.3). If a dropper is packaged with a certain medication, never use it to administer another medication, since the drop size may vary from one dropper to another. If using a syringe for oral administration, only use the type intended for oral medications, not one designed for parenteral administration. When using a dropper or oral syringe (without a needle) for infants or young children, direct the liquid toward the posterior side of the mouth. Give the drug slowly in small amounts (0.2 to 0.5 mL) and allow the child to swallow before more medication is placed in the mouth (Fig. 34.4). A nipple without the bottle attached is sometimes used to administer medication to infants. Place the medication directly in the nipple and keep the nipple filled with medication as the infant sucks so no air is taken in while the infant takes the medication. Always place the infant or young child upright (at least a 45-degree angle) to avoid aspiration. The toddler or young preschooler may enjoy using the oral syringe to squirt the medicine into his or her mouth. Older children can take oral medication from a medicine cup or measured medicine spoon.

As children adapt to swallowing tablets or capsules, administration is similar to that of adults. When helping the younger child learn how to swallow medication, the tablet or capsule can be placed at the back of the tongue or

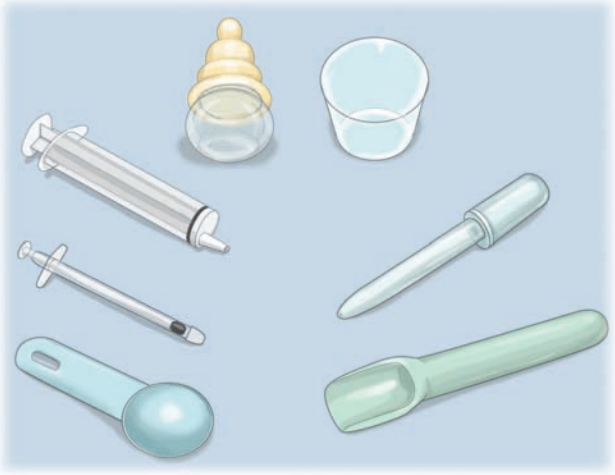

FIGURE 34.3 Devices used to administer oral medications to children.

FIGURE 34.4 Position the infant or young child for safe medication administration.

in a small amount of food such as ice cream or applesauce. Always tell children if there is medicine in the food; otherwise they may not trust you.

▶ ***Take*** NOTE!

Use the medicine cup or syringe with proper calibration instead of household cups or measuring spoons, since they are not calibrated and may deliver an incorrect dose of medication.

When the child has a nasogastric, orogastric, nasojejunal, nasoduodenal, **gastrostomy** (opening into the stomach), or jejunostomy tube, oral medications may be given via these devices. The tube allows for the medication to be placed directly into the stomach or small intestine area. Be aware that not all medications can be placed directly into the duodenum or jejunum. Medication for administration via a tube must be supplied in a liquid form, or a crushed tablet or opened capsule can be mixed with a liquid (Box 34.4). Always check tube placement prior to administering the medication. After administration, flush the tube to maintain patency.

▶ ***Take*** NOTE!

Never force an oral medication into a child's mouth or pinch the child's nose. Doing so increases the risk for aspiration and interferes with the development of a trusting relationship.

BOX 34.4 **Guidelines for Administering Medications via Gastrostomy or Jejunostomy Tubes**

- Give liquid medications directly into the tube.
- Mix powdered medications well with warm water first.
- Crush tablets and mix with warm water to prevent tube occlusion.
- Open up capsules and mix the contents with warm water to dissolve the contents and prevent tube occlusion.
- Flush the tube with water after administering medications to ensure that the entire amount of medication has been given and to prevent tube occlusion.

Adapted from Children's Healthcare of Atlanta. (2004). *Gastrostomy tube home care manual.*

Rectal Administration

The rectal route is not a preferred route for medication administration in children. The drug's absorption may be erratic and unpredictable. The method is invasive and can be extremely upsetting to the toddler and preschooler because of age-related fears and may be embarrassing to the school-age child or adolescent. However, the rectal route may be used when the child is vomiting or receiving nothing by mouth (NPO). Use age-appropriate explanations and reassurance. Helping the child to maintain the correct position may be necessary to ensure proper insertion and safety.

Lubricate the suppository well with a water-soluble lubricant. With the child in the side-lying position, insert the suppository into the rectum quickly but gently. Wear gloves or use a finger cot to insert the suppository. Insert the suppository above the anal sphincter. For an infant or child under the age of 3, use the fifth finger for insertion. For an older child, use the index finger. To prevent expulsion of the suppository, hold the buttocks together for several minutes or until the child loses the urge to defecate. If the child has a bowel movement within 10 to 30 minutes after administration of the medication, examine the stool for the presence of the suppository. If it is observed, notify the health care provider to determine if the drug needs to be administered again.

Ophthalmic Administration

Many children have a fear of having anything placed in their eyes. Provide older children with an age-appropriate explanation to gain their cooperation. Ophthalmic medications are typically supplied in the form of drops or ointment. Ensure that the medication is at room temperature, as chilled medication may be uncomfortable to the child. Proper positioning of the child is necessary to control the child's head, keep the child's hands from interfering, and prevent injury to the eye. Attempt to administer the medication when the child is not crying to ensure that the medication reaches its intended target area.

Wash hands thoroughly and don gloves. Place the child in the supine position, slightly hyperextending the neck with the head lower than the body so the medication will be dispersed over the cornea. Rest the heel of your hand on the child's forehead to stabilize it. Retract the lower eyelid and place the medication in the conjunctival sac; maintain sterile technique by being careful not to touch the tip of the tube or dropper to the sac. For eye drops, place the prescribed number of drops into the lower conjunctival sac (Fig. 34.5). For ointment, apply the medication in a thin ribbon from the inner canthus outward without touching the eye or eyelashes. If the child is old enough to cooperate, instruct the child to gently close the eyes to allow the medication to be dispersed.

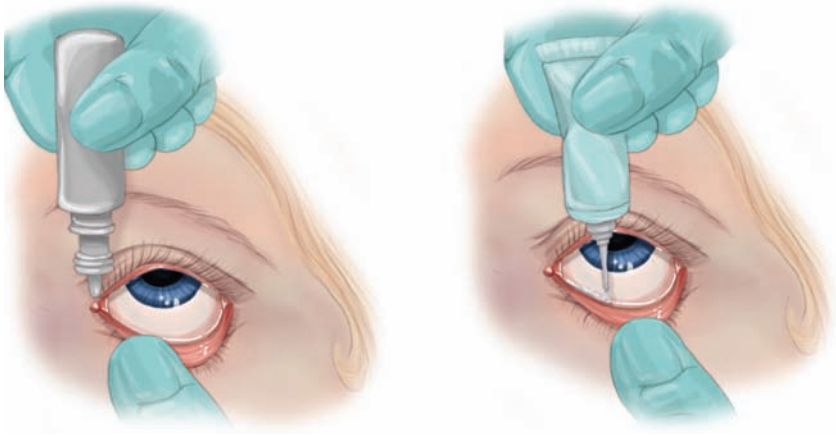

FIGURE 34.5 Administering eye drops: gently press the lower lid down and have the child look up as the medication is instilled into the lower conjunctival sac.

If a child is uncooperative, he or she may need to be immobilized in order to administer the eye drops. Alternatively, one or two drops on the inner canthus of the closed eye can be administered while the child is lying supine (Myers, Wallace, & Johnson, 2005). When the child opens his or her eye, the drop enters the eye. Always ensure that excess medication is wiped from the skin to prevent systemic absorption. Punctal occlusion after application is also important to slow systemic absorption and ensure the medicine stays in the eye.

Children often require ophthalmic medications at home. Parents or caregivers need instruction about how to administer this type of medication. Teaching Guidelines 34.1 provides information on administering eye drops and eye ointments.

Otic Administration

Medications for otic administration are typically in the form of ear drops. This route of administration can be

TEACHING GUIDELINES 34.1

Applying Eye Medications

- Wash your hands with soap and water. Dry them thoroughly using paper towels or a clean cloth.
- Allow the eye drops or ointment to come to room temperature (if the medication was stored in the refrigerator). If necessary, warm the eye drops or ointment tube in the palm of your hand. Keep the cap on to avoid any spillage.
- Remove the cap, placing it on a dry, clean surface.
- For young children (3 years or less), obtain assistance to keep their arms and fingers away during the procedure. If doing this procedure alone, wrap the child in a towel or blanket, keeping the arms inside.
- If you are applying eye drops, it may be easiest if you are standing or sitting behind the child, looking over the back of the child's head as he or she reclines. If you are applying an eye ointment, it may be easiest to face the child directly.
- Using one hand, hold the child's forehead in place while raising the eyelid with your thumb.
- With your other hand, hold the eye drop bottle or ointment tube above the eye, using an extended finger against the child's cheek, forehead, or nose to steady your hand.
- Gently squeeze the eye drop bottle, dispensing the proper number of drops, or gently squeeze the ointment tube, dispensing a small trail (about 2 cm) of ointment into the gap between the lower portion of the eye and bottom eyelid.
- Make sure the tip of the bottle or tube does not make contact with the eye or any other surface.
- For eye drops, gently press your finger against the inside corner where the eye meets the nose for about 1 minute, blocking the tears and medication from exiting through the tear duct. This will help the eye retain more of the medication. If your child is old enough, he or she may be able to do this unassisted.
- For ointment, have the child close his or her eye and not rub the area.
- Ask the child not to blink or squeeze the eye shut more than normal, as this may wash away the medication prematurely.
- Gently dab away any tears or medication on the face with a clean tissue.
- If necessary, clean the tip of the bottle or tube with a clean tissue and recap.
- Wash your hands again and dry them thoroughly.

Source: The Pediatric Glaucoma and Cataract Family Association; http://www.pgcfa.org/drops.htm, http://www.pgcfa.org/ointment.htm)

upsetting to the child because he or she cannot see what is happening. The child often receives otic drugs for an earache, and he or she may fear that the ear drops will increase the pain. Explain the procedure to the younger child in terms that he or she can understand to help allay these fears. Gain the older child's cooperation by explaining the purpose of the medication and the procedure for administration.

Reinforce the need for the child to keep the head still. Younger children may require assistance to do so. Be sure that the ear drops are at room temperature. If necessary, roll the container between the palms of your hands to help warm the drops. Using cold ear drops can cause pain and possibly vertigo when they reach the eardrum.

Place the child in a supine or side-lying position with the affected ear exposed (Fig. 34.6). Pull the pinna downward and back in children under the age of 3 and upward and back in older children. Instill the medication using a dropper. Then have the child remain in the same position for several minutes to ensure that the medication stays in the ear canal. Massage the area anterior to the affected ear to promote passage of the medication into the ear canal. If necessary, place a piece of cotton or a cotton ball loosely in the ear canal to prevent the medication from leaking.

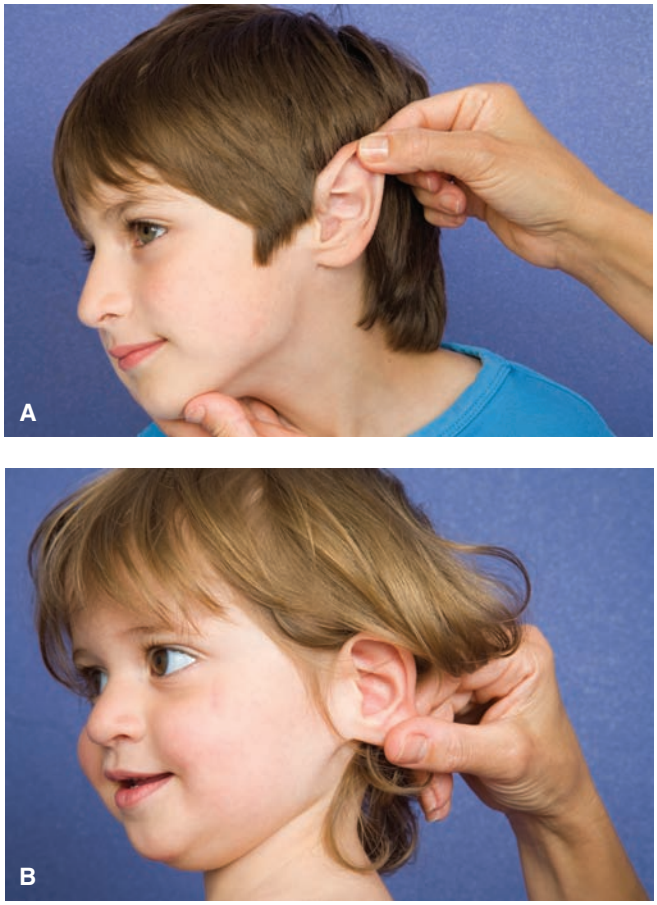

FIGURE 34.6 Administering ear drops. (**A**) For a child over age 3 years, the nurse pulls the pinna of the affected ear up and back. (**B**) For the child less than 3 years of age, the nurse pulls the pinna of the ear down and back.

Nasal Administration

Nasally administered medications are typically drops and sprays. Administering nose drops to infants and young children may be difficult, and additional help may be needed to help maintain the child's position. For nose drops, position the child supine with the head hyperextended to ensure that the drops will flow back into the nares. A pillow or folded towel can be used to facilitate this hyperextension. Place the tip of the dropper just at or inside the nasal opening, taking care not to touch the nares with the dropper (Fig. 34.7). Doing so might stimulate the child to sneeze. Although the nasal membranes are not sterile, the drop solution is, and sneezing would contaminate the dropper, leading to contamination of the drop solution when the dropper is returned to the bottle. Once the drops are instilled, maintain the child's head in hyperextension for at least 1 minute to ensure that the drops have come in contact with the nasal membranes.

For nasal sprays, position the child upright and place the tip of the spray bottle just inside the nasal opening and tilted toward the back. Squeeze the container, providing just enough force for the spray to be expelled from the container. Using too great a force can push the spray solution and secretions into the sinuses or eustachian tube.

FIGURE 34.7 Administering nose drops. Tilt the head down and back to instill nose drops.

▶ *Take* NOTE!

In young infants, instill the medication in one naris at a time, since they are obligate nose breathers.

Intramuscular Administration

Intramuscular (IM) administration delivers medication to the muscle. In children, this method of medication administration is used infrequently because it is painful and children often lack adequate muscle mass for medication absorption. However, IM administration is used to administer certain medications, such as many immunizations.

Muscle development and the amount of fluid to be injected determine IM injection sites in children. Needle size (gauge and length) is determined by the size of the muscle and the viscosity of the medication. For example, more viscous medications often require a larger-gauge needle. In addition, the needle must be long enough to ensure that the medication reaches the muscle.

The preferred injection site for infants is the vastus lateralis muscle. An alternative site is the rectus femoris muscle. The dorsogluteal site, often used in adults, is not used in children until the child has been walking for at least a year. The muscle has not fully developed and the sciatic nerve occupies a larger portion of this area in the young child. The deltoid muscle is used as an IM injection site in children after the age of 4 to 5 years of age due to the small muscle mass. Figure 34.8 illustrates IM injection sites.

Select the needle size and gauge based on the size of the child's muscle. The goal is to use the smallest length and gauge that will deposit the medication in the muscle. Table 34.3 provides general guidelines for solution amount, needle size, and needle gauge when administering IM medications.

Insert the needle into the skin at a 90-degree angle. If the child is a very small infant or has a small muscle mass, use a 45-degree angle.

Subcutaneous and Intradermal Administration

Subcutaneous (SC) administration distributes medication into the fatty layers of the body. It is used primarily for insulin administration. Subcutaneous layers differ among individuals. The preferred sites for SC administration include the anterior thigh, buttocks, upper arms, and abdomen. Use a 3/8- or 5/8-inch needle. Spread the skin tightly or pinch up the skin with the nondominant hand to isolate the tissue from the muscle. Insert the needle at a 45- to 90-degree angle, release the skin if pinched, and inject the medication slowly.

Intradermal (ID) administration deposits medication just under the epidermis. The forearm is the usual site for administration. ID administration is used primarily for tuberculosis screening and allergy testing. A 1-mL syringe with a 5/8-inch, 25- or 27-gauge needle is commonly used to administer the medication. Insert the needle beneath the skin at a 5- to 15-degree angle.

Intravenous Administration

Intravenous (IV) medication administration is commonly used with children, especially when a rapid response to a drug is desired or when absorption via other routes is difficult due to the child's illness or condition. In some cases, the IV route is the only effective method for administering a medication. Use of the IV route requires that the child have an IV device inserted, peripherally or centrally. Although insertion of this device is invasive and traumatic for the child, IV medication administration is considered to be less traumatic when compared to the trauma associated with multiple injections. Unfortunately, the veins of a child are small and easily irritated.

Most medications given by the IV route must be given at a specified rate and diluted properly to prevent overdose or toxicity due to the rapid onset of action that occurs with this route. Therefore, administering medications via the IV route requires knowledge of the drug, the amount of drug to be administered, the minimum dilution of the drug, the type of solution for dilution or infusion, the length of time for infusion, the rate of infusion, the IV tubing volume capacity, and the compatibility of various solutions and medications (Algren & Arnow, 2005). Careful maintenance of the IV site is required to prevent complications.

The primary method for IV medication administration is a syringe pump. This method provides a highly precise rate of infusion. Nursing Procedure 34.1 gives the steps for administering medication via a syringe pump.

If a pump is unavailable, the medication may be administered via a volume control device. The medication is added to the device with a specified amount of compatible fluid and then infused at the ordered rate.

Direct IV push medication typically is reserved for emergency situations and when therapeutic blood levels must be reached quickly to achieve the desired effect (Weinstein, 2006). Direct IV push administration requires that the drug be diluted appropriately and given at a specified rate, such as over 2 to 3 minutes. Care must be taken to prevent fluid overload, which may occur due to flushing needed to maintain IV patency and prevent drug incompatibilities, and from the administration of multiple drug therapies.

Providing Atraumatic Care

When administering any medication, including oral medications, use the principles of atraumatic care (see Chapters 2 and 35 for more information). Children can

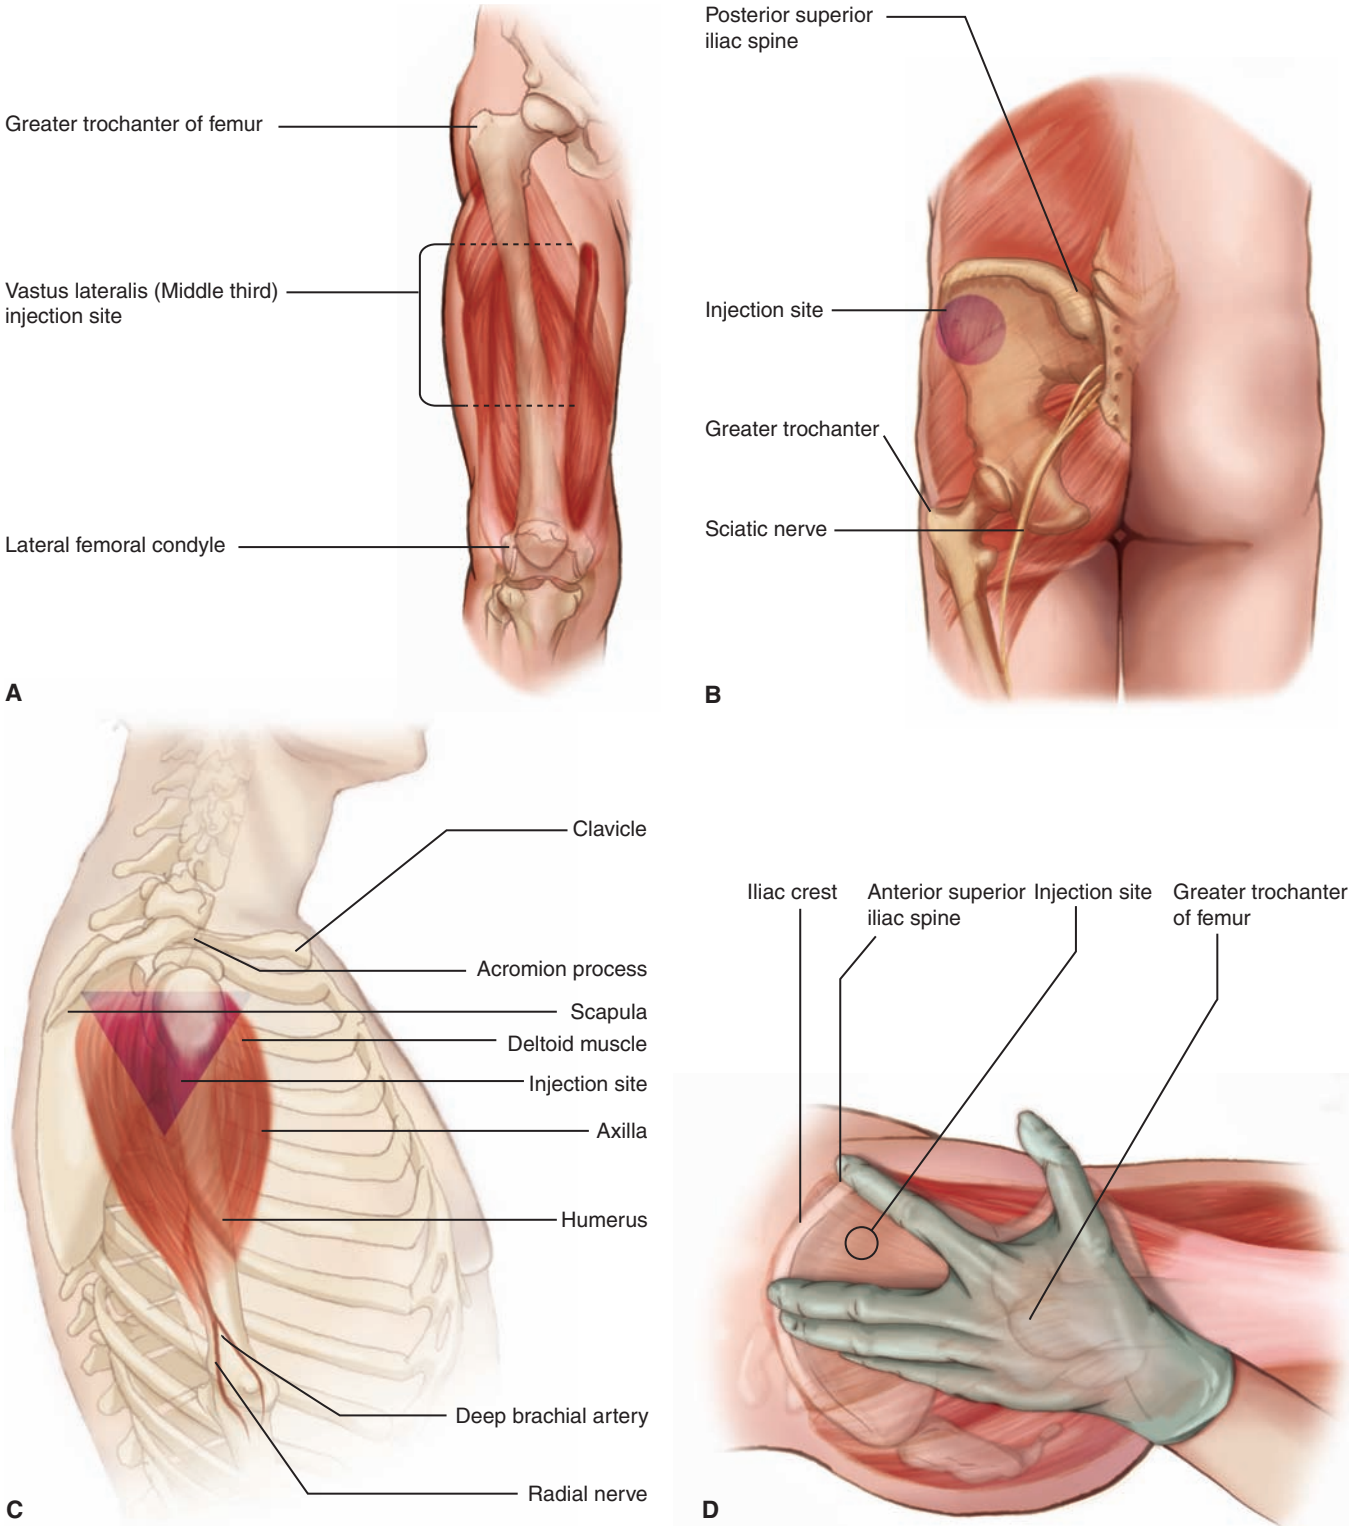

FIGURE 34.8 Locating IM injection sites. (**A**) Vastus lateralis: Identify the greater trochanter and the lateral femoral condyle; inject in middle third and anterior lateral aspect. (**B**) Dorsogluteal: Place hand on iliac crest and locate the posterosuperior iliac spine; inject in the outer quadrant formed when an imaginary line is drawn between the trochanter and the iliac spine. (**C**) Deltoid: Locate the lateral side of the humerus, one to two fingerwidths below the acromion process. Inject into upper third of muscle. (**D**) Ventrogluteal: Place palm of left hand on right greater trochanter so index finger points toward anterosuperior iliac spine, spread middle finger to form a V, and inject in the middle of the V.

TABLE 34.3 GUIDELINES FOR SOLUTION AMOUNT, NEEDLE LENGTH, AND NEEDLE GAUGE FOR IM INJECTIONS

	Solution Amount					
	Vastus Lateralis	Dorsogluteal	Ventrogluteal	Deltoid	Needle Length	Needle Gauge
Infant	0.5–1 mL	Not recommended	Not recommended	Not recommended	5/8 inch	25–27
Toddler	1 mL	Not recommended	1 mL	0.5 mL	5/8 to 1 inch	22–23
Preschooler	1.5 mL	1.5 mL	1.5 mL	0.5 mL	5/8 to 1 inch	22–23
School age	1.5–2 mL	1.5–2 mL	1.5–2 mL	0.5 mL	5/8 to 1.5 inch	22–23
Adolescent	2–2.5 mL	2–2.5 mL	2–2.5 mL	1 mL	5/8 to 1.5 inch	22–23

experience stress and fear or upset when they must take oral medications. The child may become upset or stressed when he or she must be secured snugly or positioned to minimize movement. The child may experience further discomfort if the medication has an unpleasant taste. Encourage the child to participate in care and provide the child with developmentally appropriate options, such as which fluid to drink with the medication or which flavor of ice pop to suck on before or after the administration (see Table 34.2).

To decrease discomfort and pain for the child who is to receive an injection, apply a topical anesthetic such as EMLA cream or vapocoolant spray to the site before injection (see Chapter 35 for additional information). When

Nursing Procedure 34.1

ADMINISTERING MEDICATION VIA A SYRINGE PUMP

Purpose: To provide accurate and safe administration of IV medication

1. Verify the medication order.
2. Gather the medication and necessary equipment and supplies.
3. Wash hands and put on gloves.
4. Attach the syringe pump tubing to the medication syringe and purge air from the tubing by gently filling the tubing with medication from the syringe.
5. Insert the syringe into the pump according to the manufacturer's directions.
6. Clean the appropriate port on the child's IV access device or tubing, flush the device or tubing if appropriate (e.g., an intermittent infusion device [saline lock or heparin lock]), and attach the syringe tubing to the IV tubing or device.
7. Set the infusion rate on the pump as ordered.
8. When the medication infusion is completed, flush the syringe pump tubing to deliver any medication remaining in the tubing, according to institution protocol.
9. Document the procedure and the child's response to it.

preparing the site for injection, clean it with alcohol or an antiseptic solution and allow this solution to dry.

Ensuring that the child doesn't move is essential to prevent injury. When administering an injection to a young child, at least two adults should hold him or her; this may also be necessary to help an older child to remain still. Use positions that are comforting to the child, such as those in Figure 34.1. After administration, encourage the parents or caregivers to hold and cuddle the child and offer praise.

Educating the Child and Parents

Teaching the child and parents or caregivers about medication administration is a key component of patient education. Many medications are given in the home, making the parents or caregivers the persons responsible for administration. They need to know what medications they are giving and why, how to give them, and what to expect from the drug, including adverse effects. If the medication is to be given via injection, parents and caregivers need to learn how to administer the injection properly.

Parents and caregivers commonly need suggestions about the best ways to administer the medication to their child. Provide them with tips for administration, such as mixing unpleasant-tasting medications with applesauce or yogurt or offering a favorite liquid as a chaser. Also teach the parents how to measure the amount of drug to be given. Encourage them to use a calibrated device and not a typical household spoon, which can vary in the amount that it holds. Teaching Guidelines 34.2 gives pointers about oral medication administration.

TEACHING GUIDELINES 34.2

Administering Oral Medications

- Be firm when telling your child that it is time for his or her medication. State, "It's time for your medicine" instead of asking, "Will you take your medicine?" or "Can you take your medicine for me?"
- Allow your child to choose an appropriate liquid to help swallow the medication or drink after taking it. Limit the choices to two or three.
- Never bribe or threaten your child to take his or her medication.
- Never refer to the medication as "candy."
- Be honest about the taste of the medication. If necessary, mix it with another food such as applesauce, yogurt, or syrup to help mask the taste.
- If the medication's taste cannot be masked or disguised, have your child hold his or her nose while taking the medication (taste and smell are closely related).
- Do not mix the medication with formula or baby food.
- Always check with your health care provider and pharmacy about opening capsules or crushing tablets and mixing them with food. Some medications should not be opened or crushed.
- If you are giving a liquid using an oral syringe or dropper, place the medication slowly along the inside of the cheek. Never squirt the medication forcibly to the back of the child's throat. It may cause the child to gag and spit out the medication or aspirate it into his or her lungs.
- Always praise the child after taking the medication and provide comfort and cuddling.

Intravenous Therapy

IV access provides a route for the administration of medications and fluids. It is commonly used for children because it is the quickest, and often the most effective, method of administration. As with adults, numerous sites and various devices and equipment may be used to provide IV therapy over a short or long period of time. When administering IV therapy, safety is crucial. The nurse must have a solid knowledge base about the fluids or medications to be given as well as a thorough understanding of the child's physical and emotional development. Venipuncture can be a terrifying and painful experience for children and their families. Nurses play a crucial role in providing support and education to the child and family before, during, and after the procedure (refer to Chap. 2 for additional information related to provision of atraumatic care with procedures).

Sites

IV therapy may be administered via a peripheral vein or a central vein. Peripheral IV therapy sites commonly include the hands, feet, and forearms (Fig. 34.9). In infants up to about the age of 9 months, the scalp veins may be used. The scalp veins are easily visualized, being covered only by a thin layer of subcutaneous tissue. These veins do not have valves, so the device may be inserted in either direction, although the preference would be in the direction of blood flow. However, use of a scalp vein requires that that area of the infant's head be cleared of hair to enhance visualization. They also can be frightening to parents who may think the fluid is infusing into the infant's brain. Thus, scalp veins are usually used only if attempts at other sites have been unsuccessful. When used, ensure appropriate education of the parents prior to insertion.

▶ *Take* NOTE!

When selecting an IV site in an extremity, always choose the most distal site. Doing so prevents injury to the veins superior to the site and allows additional access sites should complications develop in the most distal site.

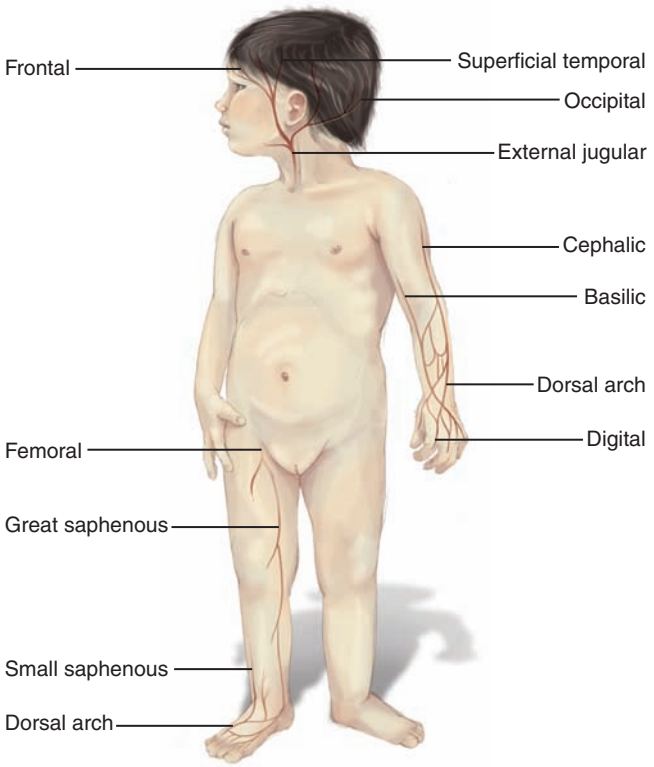

FIGURE 34.9 Preferred peripheral sites for IV insertion.

Central IV therapy usually is administered through a large vein, such as the subclavian, femoral, or jugular vein or the vena cava. The tip of the device lies in the superior vena cava just at the entrance to the right atrium. The device is inserted surgically or percutaneously and exits the body typically in the chest area, just below the clavicle. A device can be inserted via a peripheral vein, such as the median, cephalic, or basilic vein, and then threaded into the superior vena cava.

Equipment

The choice of equipment is determined by the solution or medication to be administered, the duration of the therapy, the age and developmental level of the child, the child's status, and the condition of his or her veins. Various types of IV devices are commercially available. In addition, different types of tubing and infusion control devices may be necessary.

Peripheral Access Devices

Devices used for peripheral venous access in a child include over-the-needle catheters or winged-infusion sets, commonly referred to as "butterflies" or scalp vein needles. These devices are inserted into the vein and then connected to the IV solution via tubing to provide a continuous infusion of fluid. These devices can also be inserted for intermittent use if the child does not require a continuous fluid infusion. Typically, the hub of the device is capped or plugged to allow intermittent access, such as for administering medications or obtaining blood specimens. When used in this manner, these devices are termed peripheral intermittent infusion devices or saline or heparin locks.

Needle size on the device also varies. Typically, the needle ranges from 21 to 25 gauge, depending on the child's size. The rule of thumb is to use the smallest-gauge catheter with the shortest length possible to prevent traumatizing the child's fragile veins. Typically, peripheral IV devices are used for short-term therapy, usually averaging 3 to 5 days. Midline catheters are also available. These catheters are longer than peripheral catheters and can stay in for 2 to 4 weeks. They are seated deep in the cephalic or basilic veins, but the tip does not extend past the axilla.

Central Access Devices

Numerous devices for central venous access are available. The type chosen depends on several factors, including the duration of the therapy, the child's diagnosis, the risks to the child from insertion, and the ability of the child and family to care for the device. The device may have one or multiple lumens. Although central venous access devices can be used short term, the majority are used for moderate- to long-term therapy.

Central venous access devices are indicated when the child lacks suitable peripheral access, requires IV fluid or medication for more than 3 to 5 days, or is to receive specific treatments, such as the administration of highly concentrated solutions or irritating drugs that require rapid dilution. Patient preference is also a consideration. Central venous access is advantageous because it provides vascular access without the need for multiple IV starts, thus decreasing discomfort and fear. However, central venous access devices are associated with complications such as thrombosis due to partial occlusion of the vessel and infection at the site as well as in the blood due to the direct access to the central circulation (de Jonge et al., 2005). Typically, a chest x-ray is performed after a central venous access device is inserted to verify proper placement. No fluids are administered until correct placement is confirmed. Table 34.4 describes the major types of central venous access devices.

Infusion Control Devices

Infants and young children are at increased risk for fluid volume overload compared with adults. Also, malfunction at the IV insertion site, such as infiltration, may result in much greater injury than a similar incident would cause in an adult. Therefore, IV fluids must be carefully administered and monitored. To ensure accurate fluid administration, infusion control devices such as infusion pumps, syringe pumps, and volume control sets may be used.

TABLE 34.4 TYPES OF CENTRAL VENOUS ACCESS DEVICES

Device	Description
Nontunneled central venous catheter (CVC)	Usually used short term One or more lumens Surgical or percutaneous insertion most commonly via the subclavian, internal jugular, or femoral vein with the tip of the catheter at the top of the superior vena cava just above the right atrium Useful for emergency situations Catheter sutured in place at the exit site
Peripherally inserted central catheters (PICC)	Short- to moderate-term therapy Insertion via a peripheral vein such as antecubital, basilic, cephalic, or medial antecubital vein Catheter typically threaded into superior vena cava; distal tip terminates in the superior vena cava, inferior vena cava, or proximal right atrium Insertion via saphenous vein with tip terminating in inferior vena cava above the diaphragm for infants Single or multiple lumens PICC insertion requires additional training and advanced skill.
Tunneled central venous catheter (e.g., Groshong, Hickman/Broviac)	Usually for long-term use Catheter inserted by a physician via small incision in jugular or subclavian vein and tunneled in the subcutaneous tissue under the skin Initially sutured in place to stabilize position; sutures removed after approximately 1 to 2 weeks when cuff on catheter attaches to subcutaneous tissue Single or multiple lumens Some have valves that prevent backflow of blood and air entrance.
Implanted ports (e.g., Port-a-Cath, Infus-a-Port, Mediport)	Surgically inserted by a physician Stainless-steel port with a polyurethane or silicone catheter attached Catheter tip lying in subclavian or jugular vein; port implanted under skin in a subcutaneous pocket, usually on the upper chest wall Port covered completely by skin and visible only as a slight bulging on the chest; possibly more appealing to the older child and adolescent because there are no visible parts or dressings Access to port via a specially angled, non-coring needle (Huber needle) Site preparation and pain relief measures necessary before accessing the port

Infusion pumps used for children are similar to those used for adults. Typically, the IV solution bag is attached to a calibrated volume control set that has been filled with a specified amount of IV solution (Fig. 34.10). The fluid chamber holds a maximum of 100 to 150 mL of fluid that can be infused over a specified period of time as ordered. Usually, a maximum of a 2-hour infusion amount in the chamber avoids accidental fluid overload in the pediatric population. This chamber can be filled every 1 to 2 hours so only small amounts of ordered quantities of fluid can infuse and the child is protected from receiving too much fluid volume.

In addition, syringe pumps may be used to deliver fluid and medications to children. These pumps can be programmed to deliver minute amounts of fluid over controlled periods of time (see discussion on p. 000 for additional information about syringe pumps).

Fluid Administration

Administering IV fluids to an infant or child requires close attention to the child's fluid status. Typically, the amount of fluid to be administered in a day (24 hours) is determined by the child's weight (in kg) using the following formula:

100 mL per kg of body weight for the first 10 kg
50 mL per kg of body weight for the next 10 kg
20 mL per kg of body weight for the remainder of body weight in kg

Table 34.5 gives examples of calculating a child's fluid requirements using body weight. Once the 24-hour total fluid requirement is determined, this amount is divided by 24 hours to arrive at the correct hourly rate of infusion.

FIGURE 34.10 Volume control infusion device.

Inserting Peripheral IV Access Devices

Peripheral IV devices are used for most IV therapies. Prior to insertion, review the child's diagnosis and medical history for information that may affect therapy, such as site selection or insertion. For example, a child who has a history of chronic illness may have heightened fears and anxieties related to insertion due to his or her previous experiences or difficulty in accessing IV sites. Typically, the nondominant extremity should be used for insertion, but this may not be possible if a right-handed child has a cast on his left arm.

Check the orders for the prescribed therapy. Determine the purpose and length of the IV therapy and the type of fluid or medication that is to be administered. This information aids in selecting the best device and insertion site. For example, the device needs to be of an adequate gauge to allow the solution or medication to infuse into the vein while at the same time allowing enough blood flow around the device to promote dilution of the infusion.

Establish rapport with the child and parents. Inform them about IV therapy and what to expect. Be honest with the child. Explain that the venipuncture will hurt but only for a short time. Provide the child with a time frame that he or she can understand, such as the time it takes to brush his or her teeth or eat a snack. If possible, use therapeutic play to assist the child in coping (see Chapter 32 for more information).

Insertion of an IV therapy device is traumatic. Follow the principles of atraumatic care, including the following:

- Gather all equipment needed before approaching the child.
- If possible, select a site using hand veins rather than wrist or upper arm veins to reduce the risk of phlebitis. Avoid using lower extremity veins if possible because these are associated with an increased risk of thrombophlebitis and other complications (Cook, 2007)
- Ensure adequate pain relief using pharmacologic and nonpharmacologic methods prior to insertion of the device (see Chapter 35 for more information about management of pain related to procedures).
- Allow the antiseptic used to prepare the site to dry completely before attempting insertion.
- Use a barrier such as a gauze or washcloth or the sleeve of the child's gown under the tourniquet to avoid pinching or damaging the skin.

TABLE 34.5 INTRAVENOUS MAINTENANCE FLUID CALCULATIONS BY BODY WEIGHT

<10 kg in weight	100 mL per kg of weight = # mL for 24 hours Example: A child weighs 7.4 kg. 7.4 × 100 = 740 mL (daily requirement) 740/24 = 30.8 or 31 mL/hour
11–20 kg in weight	100 mL per kg of weight for the first 10 kg + 50 mL/kg for the next 10 kg = # mL for 24 hours Example: A child weighs 16 kg. (10 × 100 = 1,000) plus (6 × 50 = 300) Total = 1,300 mL (daily requirement) 1,300/24 = 54 mL/hour
>20 kg in weight	100 mL/kg for the first 10 kg + 50 mL/kg for the next 10 kg + 20 mL/kg for each kg > 20 kg = # mL for 24 hours Example: A child weighs 30 kg. (10 × 100 = 1,000) plus (10 × 50 = 500) plus (10 × 20 = 200) Total = 1,700 mL (daily requirement) 1,700/24 = 70.8 or 71 mL/hr

- If the child's veins are difficult to locate, use a device to transilluminate the vein (shows the vein's size and direction of travel).
- Make only two attempts to gain access; if you are unsuccessful after two attempts, allow another individual two attempts to access a site. If still unsuccessful, evaluate the need for insertion of another device.
- Encourage parental participation as appropriate in helping to position the child or to provide comfort positioning, such as therapeutic hugging.
- Coordinate care with other departments such as the laboratory for blood specimen collection to minimize the number of venipunctures for the child.
- Secure the IV line using a minimal amount of tape or transparent dressing.
- Protect the site from bumping by using a security device such as the I.V. House dressing (Fig. 34.11).

Maintaining IV Fluid Therapy

Throughout the course of therapy, monitor the fluid infusion rate and volume closely, as often as every hour. If a volume control set is used to administer the IV infusion, fill the device with the allotted amount of fluid that the child is to receive in 1 hour. Doing so prevents inadvertent administration of too much fluid. Never assume that just because an infusion pump is in use, the infusion is being administered without problems. Pumps can malfunction. The tubing can become blocked, or the IV device can move out of the vein lumen. Not enough fluid, fluid overload, or infiltration of the solution into the tissues can occur.

In addition to monitoring the fluid infusion, closely monitor the child's output. Expected urine output for children and adolescents is 1.0 to 2.0 mL/kg/hour (Weinstein, 2006).

▶ **Take** NOTE!

When measuring the output of an infant or child who is not toilet-trained or who is incontinent, weigh the diaper to determine the output. Remember that 1 gram of weight is equal to 1 mL of fluid.

FIGURE 34.11 (**A**) IV House over the IV site on a child's hand. (**B**) IV House over the site on an infant's foot.

Historically, padded armboards and footboards were used to prevent movement of the IV device, but today these are considered mechanical restraints and as such should be used only as a last resort when no less restrictive method is available or effective. Padded boards also can interfere with inspection of the insertion site. They also restrict movement, increasing the risk of contractures; they may be uncomfortable; and they can irritate the underlying tissue, leading to excoriation and infection. Moreover, research has failed to demonstrate that the use of armboards promotes patency of the IV line (Algren & Arnow, 2005).

Flushing the IV line when the device is used intermittently may be necessary to maintain patency, such as before and/or after medication is administered and after obtaining blood specimens. However, there is much debate as to how often flushing should be done and the best flush solution to use, heparin or saline. Saline has been found to be more compatible with the numerous solutions and medications administered intravenously and less expensive and less irritating to the vein; also, the incidence of pain and phlebitis is less. Heparin is expensive and incompatible with numerous medications and solutions, and it can affect clotting time, depending on the concentration of the flush solution used. Evidence appears to support the use of normal saline flush with catheters larger than 24 gauge, but more studies are needed to determine the effectiveness of normal saline flushes with catheters smaller than 24 gauge. Additional research is also needed to determine the specific frequency interval for flushing and the volume and concentration of the flush solution to

use (Knue et al., 2006). Always follow your agency's policy for flushing IV lines.

If the child is receiving IV therapy via a central venous access device, provide site care using sterile technique and flush the device according to agency policy. Note the exit site for the device and inspect it frequently for signs of infection. If the device has multiple lumens, label each lumen with its use (i.e., blood specimen, medication, or fluid). Always check the compatibilities of solutions and medications being given simultaneously.

▶ *Take* NOTE!

When flushing or administering medications through a peripherally inserted central catheter (PICC) line, use a 5-mL syringe or larger, because PICC lines are fragile. Using a larger-volume syringe exerts less pressure on the PICC, thereby reducing the risk of complications.

Preventing Complications

IV therapy is an invasive procedure that is associated with numerous complications. Strict aseptic technique is necessary when inserting the device and caring for the site. Adherence to standard precautions is key. Inspect the insertion site every 1 to 2 hours for inflammation or **infiltration** (inadvertent infusion of a nonirritant solution or medication into the surrounding tissue) (Weinstein, 2006). Note signs of inflammation such as warmth, redness, induration, or tender skin. Check closely for signs of infiltration such as cool, blanched, or puffy skin. Use of a transparent dressing or IV House dressing provides easy access for assessing the IV insertion site. These types of dressings also help to prevent movement of the catheter hub, thus minimizing the risk of mechanical irritation and complications such as phlebitis or infection.

Typically, an IV site is changed every 72 hours and at any time when the integrity of the system has been compromised or contamination is suspected (Weinstein, 2006). However, with children, the 72-hour time frame may need to be adjusted to minimize the child's exposure to the repeated trauma of insertion. Follow the agency's policies and procedures related to site changes. Consider an alternative route for fluid and medication administration or the insertion of an alternative IV device, such as a PICC line. The majority of catheter-related bloodstream infections occur with the use of central venous lines. These infections result in increased morbidity, mortality, and health care costs. Prevention is paramount. Nurses need to practice proper hand hygiene, use maximal barrier protection during insertion, assess the site frequently, provide proper site care using strict sterile technique, and ensure the patient's CVC is removed as soon as it is no longer needed.

Discontinuing the IV Device

Prepare the child for removal of the IV device in much the same manner as for insertion. Many children may fear the removal of the device to the same extent that they feared its insertion. Explain what is to occur and enlist the child's help in the removal. If appropriate, allow the child to assist in removing the tape or dressing. This gives the child a sense of control over the situation and also encourages his or her cooperation. In addition, practice atraumatic care by doing the following:

- Use water or adhesive remover to help loosen the tape.
- If a transparent dressing is in place, gently lift off the dressing by pulling up opposite corners using a motion parallel to the skin surface.
- Avoid using scissors to cut the tape, but if cutting the tape is necessary, be sure that the child's fingers are clear of the tape and scissors.
- Turn off the infusion solution and pump.
- Once all tape and dressings are removed, gently slide the IV device out using a motion opposite to that used for the insertion.
- Apply pressure to the site with a dry gauze dressing and then cover with a small adhesive bandage. If possible, allow the child to choose the bandage.

▶ *Take* NOTE!

If the IV site was in the arm at or near the antecubital space, do not have the child bend his or her arm after removal of the device. Doing so increases the risk of hematoma formation.

Nutritional Support

Adequate nutrition is important for all individuals but especially for children. The quality of a child's nutrition during the growing years has a major effect on his or her overall health and development (Klossner & Hatfield, 2006). The presence of a chronic illness, disease, or trauma can increase the child's nutritional demands; if the child cannot meet these even with oral supplementation, other measures may be necessary to provide nutritional support. Such measures may include **enteral nutrition** (delivery of nutrition into the gastrointestinal tract via a tube) and **parenteral nutrition** (IV delivery of nutritional substances). The nutritional plan is determined by the child's age, developmental level, and health status.

Enteral Nutrition

Enteral nutrition, commonly called tube feedings, involves the insertion of a tube so that feedings can be delivered directly into the child's gastrointestinal tract. The tube may

be inserted via the nose or mouth or through an opening in the abdominal area, with the tube ending in the stomach or small intestine. Nasogastric or orogastric through tube feedings, a tube from the nose to the stomach or from the mouth to the stomach, respectively, are commonly referred to as **gavage feedings**. Nasoduodenal or nasojejunal feedings involve a tube that is inserted through the nose and ends in either the duodenum or jejunum. Gastrostomy feedings involve the insertion of a gastrostomy tube through an opening in the abdominal wall and into the stomach. Jejunostomy feedings are similar to gastrostomy feedings except that the tube lies in the jejunum.

Enteral nutrition is indicated for children who have a functioning gastrointestinal tract but cannot ingest enough nutrients orally. The child may be unconscious or have a severely debilitating condition that interferes with his or her ability to consume adequate food and fluids. Other conditions that may warrant the use of enteral nutrition include:

- Failure to thrive
- Inability to suck or tiring easily during sucking
- Abnormalities of the throat or esophagus
- Swallowing difficulties or risk for aspiration
- Respiratory distress
- Metabolic conditions
- Severe gastroesophageal reflux disease (GERD)
- Surgery
- Severe trauma

Enteral feedings may be given via nasogastric, orogastric, nasojejunal, nasoduodenal, gastrostomy, or jejunostomy tubes (Fig. 34.12). Table 34.6 provides additional information about these types of feeding tubes. Enteral feedings are less costly than parenteral feedings; they are considered a safer alternative for nutritional support and are associated with improved outcomes (Westhus, 2004). Tube misplacement is a serious complication of enteral feeding.

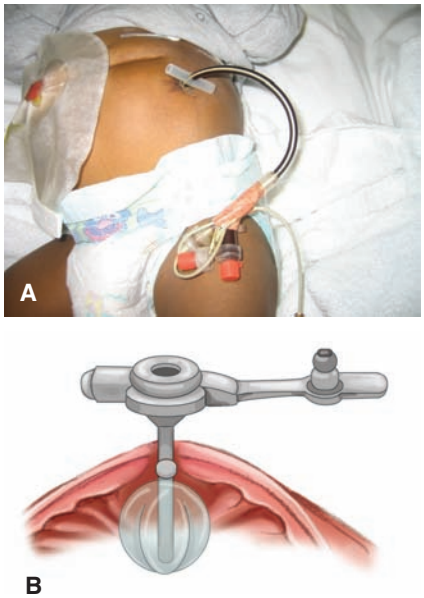

FIGURE 34.12 (**A**) Gastrostomy tube. (**B**) Low-profile (button) gastrostomy tube. The filled balloon keeps the tube in place inside the stomach.

▶ ***Take*** *NOTE!*

Small-diameter feeding tubes, though more comfortable, may easily become dislodged if the child coughs vigorously.

Inserting a Nasogastric or Orogastric Feeding Tube

Tubes for gavage feeding can be inserted via the nose or mouth. For infants, who are obligate nose breathers, insertion via the mouth may be appropriate. Oral insertion also promotes sucking in the infant. For the older child, nasal insertion is usually the preferred method. If the tube is to remain in place, the nose also is considered to be more comfortable. Nursing Procedure 34.2 gives the steps for inserting a gavage feeding tube.

Once the gavage feeding tube is inserted, checking for placement is essential. Tube placement must be confirmed each time the tube is inserted and prior to each use. Radiologic confirmation of tube placement is considered the most accurate method, but the risks associated with repeated radiation exposure to verify tube placement prohibit its use (Westhus, 2004). Several methods have been proposed as reliable for checking tube placement; but no single method has been shown to be consistently accurate for continually assessing tube placement. Refer to Box 34.5 for methods to verify feeding tube placement.

Even with these methods, tube malpositioning can occur. Research also has suggested using measurements of bilirubin, trypsin, and pepsin levels to enhance assessment of tube placement, but no methods are available for bedside testing of these levels (Huffman et al., 2004). Therefore, nurses need to be vigilant in checking for tube placement using the recommended methods and be cautious and proactive if there is any suspicion that the tube may be misplaced.

If the gavage feeding tube is to remain in place, secure it to the child's cheek. Do not tape the tube to the child's forehead because this could lead to irritation and pressure on and possible breakdown of the nasal mucosa. Also measure the length of the tube extending from the nose or mouth to the end and record this information. Double-check this measurement before administering each intermittent tube feeding to verify that the feeding tube is in the proper position. Once the position of the gavage feeding tube is confirmed, the feeding solution or medication can be administered.

TABLE 34.6 TYPES OF ENTERAL FEEDING TUBES

Type of Tube	Indication	Nursing Implications
Nasogastric (inserted via the nose into the stomach) Orogastric (inserted via the mouth into the stomach)	Short-term enteral feeding. Orogastric usually limited to young infants only.	• Long-term use or repeated insertion causes irritation and discomfort. • Silicone and polyurethane tubes are very flexible and more comfortable; they require a stylet or guidewire for insertion. • Length of long-term use varies according to the type of tube used and the institution protocol. Periodically a nasogastric tube is removed and reinserted via the opposite nostril to prevent pressure on the nasal mucosa. • Maintaining orogastric placement between feedings can be difficult due to oral secretions.
Nasoduodenal (inserted via the nose to the duodenum) or nasojejunal (inserted via the nose to the jejunum)	Short-term enteral feeding. Indicated if child has trouble digesting food, cannot use his or her gastrointestinal tract secondary to congenital anomalies or surgery, or is at risk for or has a history of severe reflux or aspiration.	• Silicone and polyurethane tubes with weighted tip allow tube to pass from pylorus into small intestines. • Agency may require special training in order to place at bedside; may also be performed in radiology. • Length of use same as nasogastric or orogastric tubes.
Gastrostomy (surgically inserted through the abdominal wall into the stomach) Jejunostomy (surgically inserted through the abdominal wall into the jejunum)	Long-term enteral feeding or when esophageal atresia or stricture is present. Jejunostomy tubes are indicated when gastric feeding is not tolerated.	• The inner section of the tube is below the skin surface with the tip located in the stomach or jejunum (may be balloon, winged, or mushroom-shaped). The outer section appears above the skin surface at the insertion site and has an opening or feeding port to which the feeding solution is attached. • Low-profile gastrostomy device (gastrostomy button) is flush with the abdominal surface. The flip-top opening is anchored by a dome that fits against the stomach wall. Less conspicuous, it allows the child to be more active and mobile. • After initial insertion, the tube length is measured from the insertion site to the far end of the tube and recorded. This measurement is checked at least daily to ensure that the tube has not moved. • For any gastrostomy or jejunostomy tube, the type and size of tube inserted as well as the amount required to fill the balloon if present should be known.

▶ *Take* NOTE!

Instilling air into the tube and then auscultating for the sound is no longer considered a viable method for checking tube placement. Air instilled into a tube that is positioned above the gastroesophageal sphincter can still be auscultated as air in the stomach, thereby giving a false-positive result.

Remember Lily, the 9-month-old infant diagnosed with failure to thrive who is to receive gavage feedings with a nasogastric tube? What equipment will be needed, and what steps will you take to complete the procedure?

Administering Enteral Feedings

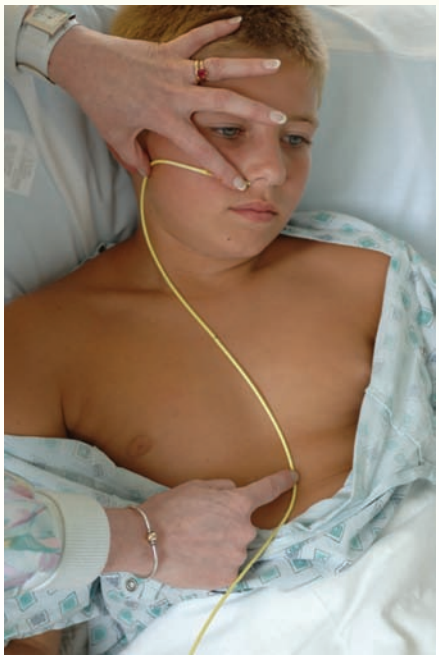
Enteral feedings can be given continuously or intermittently, regardless of the type of tube used. Intermittent

Nursing Procedure 34.2

Inserting a Gavage Feeding Tube

Purpose: To provide a means for delivering nutrition to the child's functioning gastrointestinal tract

1. Verify the order for gavage feeding.
2. Explain the procedure to the child and parents using appropriate language geared to the child's development level.
3. Gather the necessary equipment; remove formula for feeding from refrigerator if appropriate and allow it to come to room temperature.
4. Wash hands and put on gloves.
5. Inspect the child's nose and mouth for deformities that may interfere with passage of the tube.
6. Position the infant supine with the head slightly elevated and with the neck slightly hyperextended so that the nose is pointed upward. If necessary, place a rolled towel or blanket under the neck to help in maintaining this position. Assist the older child to a sitting position if appropriate. Alternatively, have the parent or another person hold the child to promote comfort and reassurance. Enlist the aid of additional persons, such as a parent or other health care team member, to assist in maintaining the child's position.
7. Determine the tubing length for insertion: measure from the tip of the nose to the earlobe to the middle of the area between the xiphoid process and umbilicus. Mark this measurement on the tube with an indelible pen or with a piece of tape.
8. Lubricate the tube with a generous amount of sterile water or water-soluble lubricant to promote passage of the tube and minimize trauma to the child's mucosa.
9. Insert the tube into one of the nares or the mouth. Direct a nasally inserted tube straight back toward the occiput; direct an orally inserted tube toward the back of the throat.
10. Advance the tube slowly to the designated length; encourage the child (if capable) to swallow frequently to assist with advancing the tube.
11. Watch for signs of distress, such as gasping, coughing, or cyanosis, indicating that the tube is in the airway. If these signs develop, withdraw the tube and allow the child to rest before attempting reinsertion.
12. Check for proper placement of the tube by attaching a syringe to the end of the tube and aspirating stomach contents; the pH of the aspirate should be less than 6 (indicating gastric acid) and the color of the aspirate should be clear, tan, or green (indicating gastric secretions); return any aspirated contents to the stomach.
13. Document the type of tube inserted, length of tubing inserted, measurement of external tubing length after insertion, and confirmation of placement.



BOX 34.5 Methods for Verification of Feeding Tube Placement

- Obtain radiographic confirmation of proper tube placement after initial placement.
- After initial confirmation, document pH of aspirate; document insertion distance and external length of tube in the chart. Mark and document the tube's exit site from the nose or mouth.
- Use bedside techniques at regular intervals to determine proper tube positioning.
  - Measuring pH
    - Gastric secretions have a pH < 5. Small intestine secretions will usually have a pH > 6, but this does not reliably predict proper tube placement. A pH > 6 can occur with respiratory or esophageal placement, with proper tube placement (gastric or intestinal) when feedings are given continuously, or if the child is receiving acid-inhibiting medications. Therefore, if the pH is > 5 additional assessment is warranted.
  - Observing appearance of fluid aspirated from tube
    - Gastric secretions are usually grassy green or clear and colorless and can have off-white or tan mucus shreds. It may also be brown-tinged if blood is present.
    - Intestinal secretions are often bile stained, light golden yellow to brownish green. They tend to be thicker and more translucent than gastric secretions.
    - Respiratory secretions can be white, yellow, straw colored, or clear.
  - Check external markings on tube and external tube length to determine if the tube seems to have migrated or been misplaced.
  - Continually assess for signs indicative of feeding tube misplacement, such as unexplained gagging, vomiting, or coughing; signs and symptoms of respiratory distress; and decreased oxygen saturations.
  - Review routine chest and abdominal x-rays (if obtained) to double check correct tube position.

*Note: Always follow agencies' policy and procedures.

feedings are commonly called **bolus feedings**. With a bolus feeding, a specified amount of feeding solution is given at specific intervals, usually over a short period of time such as 15 to 30 minutes. Given via a syringe, feeding bag, or infusion pump, bolus feedings most closely resemble regular meals. Continuous feedings are given at a slower rate over a longer period of time. In some cases, the feeding may be given during the night so that the child can be free to move about and participate in activities during the day. For continuous feedings, an enteral feeding pump is used to administer the solution at a prescribed rate.

Checking for tube placement is a priority before administering any intermittent tube feeding and periodically during continuous tube feedings, regardless of the type of tube being used. (Refer to Table 34.6.) For gastrostomy and jejunostomy tubes, ensure that the calibration, if present, has not changed. Measure the length of the tube daily from the exit site on the stomach to the end of the tube. Aspiration of stomach contents is still recommended in some literature, and checking the pH can assist in verifying proper placement. Once placement is confirmed, the feeding can be given. Also, measure the gastric **residual** (the amount remaining in the stomach; indicates gastric emptying time) by aspirating the gastric contents with a syringe, measuring it, and then replacing the contents. Check the residuals periodically, according to the facility's policy, such as every 4 to 6 hours, and before each intermittent feeding. If the residual volume exceeds the amount specified by the physician's order, hold the feeding and notify the physician.

Begin the feeding by placing the child in a supine position with the head and shoulders elevated approximately 30 degrees so that the feeding will remain in the stomach area. Flush the tube with a small amount of water to clear it and prevent occlusion. This is not necessary for a gavage feeding if the tube is being inserted each time a feeding is given. Ensure that the feeding solution is at room temperature. Administer the feeding as per the facility's policy.

Feeding solutions may be placed into the barrel of a syringe or into a feeding bag attached to the feeding tube and allowed to flow by gravity. The rate of flow for gravity-assisted feedings can be increased or decreased by raising or lowering the feeding solution container, respectively. Typically, intermittent feedings last from 15 to 30 minutes. A feeding bag also may be attached to a pump to control the rate of flow. Monitor the child's tolerance to the feeding.

Once the feeding is complete but before the formula completely empties from the container, flush the tube with water. As the water leaves the syringe or tubing, clamp the tube to prevent air from entering the stomach. Then disconnect the syringe or tube-feeding bag from the tube (Children's Healthcare of Atlanta, 2004).

▶ ***Take*** NOTE!

If the child vomits during the feeding, stop the feeding immediately and turn him onto his side or sit him up.

If the child has a gastrostomy button, open the cap and connect an adaptor or insert extension tubing through the one-way valve. This allows access to the gastric conduit. The feeding solution container is connected to the extension tubing or adaptor and the feeding is given as de-

EVIDENCE-BASED PRACTICE 34.1

Feeding Tube Aspirates, pH, and Enzyme Content as Accurate Predictors of Proper Feeding Tube Placement in Children

Nutritional support is essential in the care of ill children. Many patients require enteral feedings to obtain proper nutrition during illness. Feeding tube placement errors can have a negative impact. Tubes inadvertently placed in the esophagus or in the stomach when they should have been in the intestines increase the risk for aspiration. Tubes placed in the intestines that were intended to be in the stomach can lead to malabsorption and diarrhea. Tubes placed in the lungs can have catastrophic, even fatal results. Extreme care needs to be taken to ensure correct positioning of a feeding tube prior to use. Radiography is the most accurate way to determine that a feeding tube is in the desired location and not inadvertently in the lung. The risk of repeated exposure to radiation makes it unrealistic to use radiography every time feeding tube placement needs to be confirmed.

● Study

A prospective descriptive clinical study was performed at a university-based children's hospital. A convenience sample of 56 children, from birth to 14 years, who required feeding tubes—nasogastric, orogastric, or nasointestinal—was used. Placement of the feeding tube was checked 30 minutes after radiologic confirmation by aspirating 2.5 mL of fluid. The appearance of the fluid was described, pH was determined by two methods, and the aspirate was assayed for pepsin and trypsin content.

▲ Findings

Mean gastric pH was significantly lower than mean intestinal pH. Color of the gastric aspirate (clear and colorless, green, off-white, or brown) was significantly different than the intestinal aspirate (yellow or bile stained). Both enzymes, pepsin and trypsin, were statistically significant discriminators between gastric and intestinal tube placement. Aspirating fluids from feeding tubes, visually examining the fluid, and assaying the fluid for aspirate characteristics were found to be adaptable from adults to children.

■ Nursing Implications

Nurses need to utilize accurate assessment skills when verifying feeding tube placement. Nurses can feel more confidence that simple bedside tests, such as pH and visual appearance of aspirate, can provide evidence that a feeding tube is placed properly in the stomach. When pH is > 6 and the aspirate's visual appearance is yellow or bile colored, this may indicate intestinal placement, but further assessment and verification is still warranted. Refer to Box 34.5 for further explanation.

Westhaus, N. (2004). Methods to test feeding tube placement in children. *American Journal of Maternal Child Nursing, 29*(5), 290–291.

scribed previously. After the feeding is completed, the extension tubing or adaptor is flushed with water and the flip-top opening is closed.

Burp the infant during and after any type of tube feeding in the same manner as for an infant who is bottle- or breast-fed. Also, position the child on his or her right side with the head slightly elevated, approximately 30 degrees, for about 1 hour after the feeding to facilitate gastric emptying and reduce the risk of aspiration and regurgitation. Weigh the child daily throughout enteral nutrition therapy to determine the effectiveness of the therapy.

Providing Skin and Insertion Site Care

Skin around the insertion gastrostomy or jejunostomy site may become irritated from movement of the tube, moisture, or leakage of stomach or intestinal contents, or due to the adhesive device holding the tube in place. Keeping the skin clean and dry will help prevent most of these problems (Children's Healthcare of Atlanta, 2004). Routine site care includes gentle cleansing with soap and water followed by rinsing or cleaning with water alone.

▶ ***Take*** *NOTE!*

Do not rotate a jejunal tube because it can cause kinking (Cincinnati Children's Hospital Medical Center, 2005).

The skin around a gastrostomy or jejunostomy tube requires cleaning at least once a day. Ordinary soap and water are sufficient to clean about the tube site to prevent buildup. To clean under an external disc or bumper, a cotton-tipped applicator may be used. Diluted hydrogen peroxide may be necessary to clean crusted drainage (Cincinnati Children's Hospital Medical Center, 2005). During insertion site care, rotate the gastrostomy tube or button a quarter-turn to prevent skin adherence and irritation (Children's Healthcare of Atlanta, 2004). Assess the insertion site and condition of the surrounding skin for signs and symptoms of infection, such as erythema, induration, foul drainage, or pain. A small amount of clear

or tan drainage is normal. If any drainage is present, a dressing can be placed. This dressing should be changed when soiled. If no drainage is present, do not place a dressing as it can cause undue pressure.

Preventing movement of the tube also helps reduce skin irritation. Check the volume of the balloon with a balloon-tipped device about once or twice a week and reinflate the balloon to the initial volume if needed. The tube should be able to move slightly in and out of the child's stomach. The plastic disc should be snug against the skin but not tight enough to cause pressure. Tube stabilization methods help prevent the tube from moving around and sliding further into the stomach or jejunum. Stabilize the tube by pulling gently on the tubing and sliding the stabilizer bar or disc snugly against the abdomen. Then, measure and record the length of the tube from the exit site of the abdominal wall to the end of the tube. All future measurements should be the same unless the tube length is changed. For tubes without a stabilizer bar or disc or for additional stabilization needs, several other methods may be used, including nipples, tape, tension loops, and hydroactive dressings (Box 34.6).

Promoting Growth and Development

Some children receive all of their nutritional needs through tube feedings, whereas other children use tube feedings as a supplement to eating by mouth. Feeding time is a special time for infants and children. Occasionally, babies who are fed solely through an enteral feeding tube may forget or lose the desire to eat by mouth. Use a pacifier to help avoid this, allowing the infant to associate the nipple in his or her mouth with a feeding. The sucking motion will also exercise the jaw and promote the flow of the feedings. The saliva produced during sucking aids in digestion. Combined with holding the infant and cuddling, rocking, and talking to him or her, this promotes a more normal feeding time.

Talking with children, playing music, or reading a story promotes an active feeding time. At home, encourage parents to include the feeding as a part of regular family mealtime together to provide socialization for the child. Allow the child to participate in the feedings by gathering supplies and administering the actual feeding so that the child may experience independence and adaptation. If the child also eats food by mouth, feed him or her by mouth first and then administer the tube feeding. During tube feedings in bed, make sure the head of the bed is elevated at least 30 degrees to help prevent vomiting and aspiration.

Children with feeding tubes should be allowed as normal a routine as possible. For example, they can crawl, walk, and jump just like children of the same age and developmental level. However, in some cases, contact sports such as football, hockey, and wrestling should be avoided because of the higher risk of injury. Securing the tubing under the child's clothing will prevent it from becoming accidentally dislodged. Dressing younger children in one-piece outfits helps to prevent them from playing with the gastrostomy or jejunostomy tube and helps to protect the insertion site (Fidanza, 2005).

Educating the Child and Family

Educate children receiving enteral feedings and their parents thoroughly about this method of nutritional support. Reinforce the reason for the therapy and provide the child and parents with opportunities to verbalize their concerns and ask questions. Ensure that the parents understand the risks and benefits of the therapy and the expected duration.

Provide the child, if developmentally appropriate, and parents with opportunities to participate in the feeding sessions. This helps allay some of their fears and anxieties and promotes a sense of control over the situation. They will also gain valuable practice in learning the skill should the feedings be required at home. Teaching Guidelines 34.3 identifies important topics to include in the teaching plan for a child receiving enteral nutrition at home. Education also involves helping the family develop appropriate coping strategies to adapt, solve problems, and negotiate for the support and services they will need after discharge.

Remember Lily from the beginning of the chapter? She is to be discharged home after having a gastrostomy tube inserted to continue feedings at home.

What teaching is needed for her family prior to discharge?

Parenteral Nutrition

Nutritional support can be administered IV through a peripheral or central venous catheter. The concentration and components of the solution determine the type of parenteral nutrition. Parenteral nutrition given via a central venous access is termed **total parenteral nutrition (TPN)**. Comparison Chart 34.1 gives information about peripheral and central parenteral nutrition.

Administering TPN

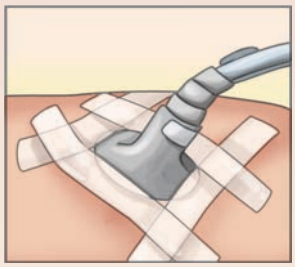
Typically, the health care provider determines the concentration and components of the TPN solution based on a thorough assessment of the child's status, including the results of laboratory testing. This information is used as a baseline for evaluating the effectiveness of therapy.

The solution is prepared under sterile conditions in the pharmacy. For TPN, a central venous access device is inserted and secured, if one is not already in place. Use specialized tubing with an in-line filter (0.22 μm) to prevent small microparticles from entering the circulation. If total nutrient admixture (TNA) is being administered, the use of a 1.2-μg filter is recommended.

BOX 34.6 Methods to Stabilize a Gastrostomy Tube

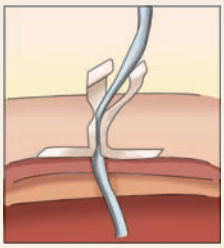
Nipple Method

1. Cut a piece of skin protectant (e.g., Stomahesive®) to fit around the G-tube, leaving a small amount of skin showing around the tube.
2. Cut a half-inch from the top of a baby-bottle nipple, just large enough to fit snugly over the tube. Cut three or four holes at the base of the nipple to allow air circulation and site assessment. Slip the nipple over the tube.
3. Secure the tube to the Stomahesive® with four pieces of 1-inch-wide tape around the base of the nipple. Do not cover the holes in the nipple.
4. Gently pull on the tube until slight resistance is felt, anchoring the tube against the stomach or intestinal wall.
5. Place another piece of 1-inch-wide tape where the tube meets the nipple, securing the tube in place.



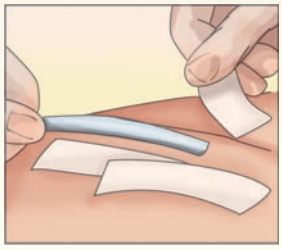
Taping Methods

1. Cut two pieces of 1-inch-wide tape about 4 to 5 inches long.
2. Fold a tab down on each piece of tape.
3. Tape the pieces to the skin and along opposite sides of the tube, sandwiching them together.

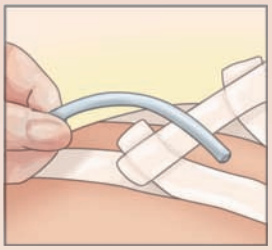


OR

1. Cut two pieces of tape about 6 inches long.
2. Form pieces into two tabs by folding the middle third of each one so it will stick onto itself. Apply these two tabs on either side of the tube directly onto the skin.

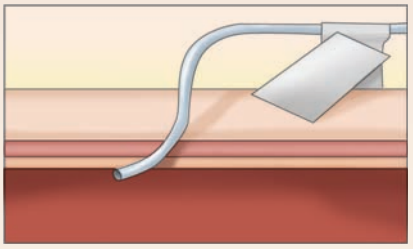


3. Cut a third piece of tape about 8 inches long, using it to go from one tab over the G-tube to the other tab and back again, leaving space at the tube insertion point. This forms an H with the two tabs.



Tension Loop Method

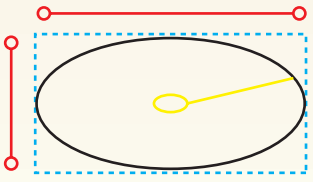
1. Fold the middle third of a piece of tape onto itself. Place the tape onto the skin about 2 to 3 inches from the tube insertion site.
2. Fold each end of a second piece of tape onto itself to make two tabs. Fold this around the tube 3 inches away from the tube insertion site.
3. Tape the two pieces together, keeping the tube at a 90-degree angle from the abdomen.



Hydroactive Dressing Method

This method of securing a tube may be used if there is skin breakdown or irritation at the insertion site.

1. Cleanse the skin with soap and water, then rinse. Dry well.
2. Cut a 2-by-3-inch piece of hydroactive dressing material, rounding off the corners. Cut through to the center and then cut a small hole the size of the tube.
3. Remove the paper backing off the hydroactive dressing and apply it to the skin, fitting snugly around the tube.



4. Reapply a new dressing every 3 to 5 days or when it becomes wet.

Adapted from Children's Healthcare of Atlanta. (2004). *Gastrostomy tube home care manual.*

TEACHING GUIDELINES 34.3

Topics to Be Covered for Home Enteral Nutrition

- Type of nutritional support
- Rationale for therapy
- Expected results from therapy
- Duration of therapy
- Frequency of feedings
- Feeding solution and equipment
- Tube insertion technique (if appropriate)
- Methods to check for correct placement
- Steps for administering the feeding (and medication if ordered)
- Procedure for flushing tube
- Frequency of weighing the child
- Signs and symptoms of complications and when to notify health care provider
- Troubleshooting problems, such as clogging of the tube
- Daily tube care (e.g., cleaning the site, rotating tube)
- Site assessment
- Technique for reinsertion/replacement of tube as appropriate
- Equipment suppliers
- Resources for support
- Follow-up visits and referrals

The infusion of the solution is initiated at a slow rate that is gradually increased as ordered based on how the child tolerates the therapy. TPN solutions are highly concentrated glucose solutions that can cause hyperglycemia if given too rapidly. Use of an infusion pump is essential to control the rate of infusion. TPN solutions may be refrigerated until they are to be used. Once started, a single solution of TPN should hang for no longer than 24 hours. Fat emulsions are administered periodically to meet the child's need for essential fatty acids. These solutions are given as a piggyback solution into the TPN line, but below the in-line filter.

Throughout TPN therapy, be vigilant in monitoring the infusion rate, and report any changes in the infusion rate to the health care provider immediately. Adjustments may be made to the rate, but only as ordered by the provider. The infusion rate should never be adjusted more than 10% higher or lower than the current rate (Weinstein, 2006).

Check blood glucose levels frequently, such as every 4 to 6 hours, initially to evaluate for hyperglycemia. These levels can be obtained with a bedside glucose meter. Minimize the trauma and discomfort associated with frequent invasive procedures by using the principles of atraumatic care. If blood glucose levels are elevated, subcutaneous administration of insulin may be needed. Once the child's glucose levels stabilize, the frequency of blood glucose level determinations decreases, such as every 8 to 12 hours, based on the facility's policy.

▶ *Take* NOTE!

If for any reason the TPN infusion is interrupted or stops, begin an infusion of a 10% dextrose solution at the same infusion rate as the TPN. This helps to prevent rebound hypoglycemia that may occur due to the increased insulin secretion by the child's body in response to the use of the highly concentrated TPN solution.

COMPARISON CHART 34.1 PERIPHERAL PARENTERAL NUTRITION VS. TOTAL PARENTERAL NUTRITION

	Peripheral Parenteral Nutrition	Total Parenteral Nutrition
Indications/use	Primarily supplemental Short-term use to supply additional calories and nutrients	Provides all nutrients to meet child's needs Enough calories supplied to maintain a positive nitrogen balance (Weinstein, 2006)
Route	Peripheral vein	Central venous access to allow rapid dilution of hypertonic solution
Child's status	Nutritional status usually within acceptable parameters Oral intake decreased or absent	Child with a nonfunctioning GI tract, such as a congenital or acquired GI disorder Severe failure to thrive Multisystem trauma or organ involvement Preterm newborns
Components	Fluid, electrolytes, and carbohydrates (dextrose); usually no protein or fats Carbohydrate concentration usually limited to 10% (Weinstein, 2006)	Highly concentrated solution of carbohydrates, electrolytes, vitamins, and minerals Lipid emulsion to supply need for essential fatty acids Total nutrient admixture (TNA) with components of TPN plus lipids and other additives in one container

Perform catheter site care, tubing and filter changes, and dressing changes according to the facility's policy. Inspect the insertion site closely for signs of infection. Also monitor the child's vital signs, daily weights, and intake and output closely for changes. In addition, review laboratory test results, which can aid in early detection of problems, such as infection or electrolyte excesses or deficits.

TPN can be administered continuously over a 24-hour period, or after initiation it may be given on a cyclic basis, such as over a 12-hour period during the night. When administering cycled TPN, the solution is infused at half the prescribed rate for the first and last hour to prevent hyper- and hypoglycemia.

Preventing Complications

Nurses play a key role in minimizing the risk for complications related to use of central venous access devices and TPN. Box 34.7 describes these complications. Key measures to reduce the risk of complications include the following:

- Monitor the child's vital signs closely for changes.
- Adhere to strict aseptic technique when caring for the catheter and administering TPN.
- Ensure that the system remains a closed system at all times. Secure all connections, use occlusive dressings, and clamp the catheter or have the child perform the Valsalva maneuver during tubing and cap changes.
- Adhere to agency policy for flushing of the catheter and maintaining catheter patency.
- Assess intake and output frequently.
- Monitor blood glucose levels and obtain laboratory tests as ordered to evaluate for changes in fluid and electrolytes.

▶ *Take* NOTE!

Never administer any medication, blood, or other solution through the TPN lumen. Doing so increases the risk for contamination of the system and subsequent infection.

Promoting Growth and Development

Meals are a time for meeting nutritional needs as well as a time for love, comfort, support, and socialization. TPN meets the child's nutritional needs, but the child's need for love and support also must be met. Implement measures similar to those for children receiving enteral nutrition (see discussion earlier in this chapter). Also provide opportunities for holding and cuddling the child. Allow the older child to participate in activities that can help to occupy the time associated with meals. Encourage the child and parents to participate in the care to promote a sense of independence as well as a sense of control over the situation.

Educating the Child and Family

Children who require long-term TPN therapy may receive TPN in the home. Administering TPN at home requires thorough education of the child and parents. This teaching can occur in the health care agency or in the child's home. The amount of information to be taught can be overwhelming, so ensure that ample time is available. Allow time for questions and concerns. Offer emotional support and guidance whenever necessary.

Provide written and verbal instructions about the care involved. Have the child (if appropriate) and parents demonstrate the care needed, including care of the central venous access device. Review with them the measures for obtaining, storing, and handling the solutions and supplies. Develop plans for troubleshooting problems with devices and equipment, and give instructions on how to recognize and treat complications. Also teach them about danger signs and symptoms that require immediate notification. Be sure they have the name and number of a contact person in case of emergency situations.

Initiate the appropriate referrals for support. Specialized home care infusion services are available for follow-up in the home. In addition, social services can be helpful in providing assistance with finances, health insurance

BOX 34.7 Complications that can Occur with Central Venous Access Devices and TPN

- Air embolism from inadvertent entry of air into the system during tubing or cap changes or accidental disconnection
- Cardiac tamponade due to catheter advancement with movement of the arm, neck, or shoulder
- Catheter occlusion from the development of a fibrin sheath or thrombus at the catheter tip, malpositioning or kinking, or the deposition of precipitates or a blood clot
- Venous thrombosis from injury to the vessel wall during insertion or movement of the catheter after insertion or from chemical irritation due to administration of concentrated solutions, vesicants, and other medications through the catheter
- Hyperglycemia, typically with too rapid an infusion of TPN
- Hypoglycemia, which may occur with rapid cessation
- Dehydration as the child's body attempts to rid itself of excess glucose through renal excretion
- Electrolyte imbalance (particularly potassium, sodium, calcium, magnesium, and phosphorus)
- Infection at the skin insertion site, along the catheter pathway, or in the bloodstream. Organisms can arise from the skin, hands of caregivers, or other areas such as wound drainage, droplets from the lungs, or urine. For example, connection sites can be contaminated during tubing or dressing changes.

reimbursement, scheduling, transportation, emotional support, and community resources.

Key Concepts

- Children and families need appropriate explanation and education before a procedure is performed. Preparation may include explaining the procedure as well as physically preparing the child. Appropriate preparation helps to decrease the child's and family's anxiety, promote the child's cooperation, and support the child's and family's coping skills.
- The "eight rights" of pediatric medication administration are the right drug, right dose, right route, right time, right patient, right documentation, right to be educated, and right to refuse.
- The physiologic immaturity of some body systems in children can affect a drug's pharmacodynamics, leading to differences in the body's response to the drug and thus enhancing or diminishing the drug's effects. The child's age, weight, body surface area, and body composition can affect the drug's pharmacokinetics.
- The two most common methods for determining pediatric drug doses involve the use of the child's body weight and body surface area.
- Children under the age of 5 to 6 are at risk for aspiration when receiving tablets or capsules because they have difficulty swallowing them; liquids may be more appropriate. When administering oral medications to children, always tell them whether a medication is being mixed with food.
- Medication administration via the rectal route is not preferred because the drug's absorption may be erratic and unpredictable and children find this route extremely upsetting or embarrassing.
- When administering otic medications, pull the pinna downward and back if the child is under age 3, up and back for older children.
- Intramuscular administration is used infrequently in children because it is painful and children often lack the adequate muscle mass. When used with infants, the preferred site is the vastus lateralis muscle.
- Administration of medication via the IV route is common with children, especially when a rapid response to the drug is desired or when absorption via other routes is difficult or impossible. The primary method for IV medication administration is via a syringe pump.
- Preferred sites for peripheral IV therapy include the veins of the hands, feet, and forearms. The scalp vein may be used in infants but only if attempts at other sites have been unsuccessful. The rule of thumb for insertion of any peripheral devices is to use the smallest-gauge catheter for the shortest length of time possible to prevent trauma to the child's fragile veins.
- Central venous therapy usually is administered through a large vein, such as the subclavian, femoral, or jugular vein or vena cava. The tip of the device lies in the superior vena cava just at the entrance to the right atrium. Devices include single- or multiple-lumen short- and long-term catheters, peripherally inserted central catheters, tunneled catheters, and vascular access ports.
- Monitoring intake and output is important when a child is receiving IV therapy. Site inspection, proper care of the site, and proper dressing changes are key to preventing complications.
- Nutritional support can be administered enterally via a nasogastric or orogastric tube (gavage feeding) or via a gastrostomy or jejunostomy device or administered parenterally through a peripheral or central venous access device.
- Enteral nutrition is indicated for children who have a functioning gastrointestinal tract but cannot consume adequate amounts of nutrients orally.
- Prior to any enteral feeding, placement of the feeding tube must be confirmed. The gold standard for confirming placement is with an x-ray. At the bedside, checking the color and pH of the aspirate is used to confirm placement.
- Children receiving TPN require close monitoring of the infusion rate and volume, intake and output, vital signs, and blood glucose levels. Strict aseptic technique is necessary when caring for the central venous access site and TPN infusion.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. A nurse is preparing to administer an intramuscular injection to an infant. What is the most appropriate site for this injection?
   a. Deltoid muscle
   b. Vastus lateralis
   c. Dorsogluteal
   d. Rectus femoris
2. A 3-year-child is to receive a medication that is supplied as an enteric-coated tablet. What is the best nursing action?
   a. Crush the tablet and mix it with applesauce.
   b. Dissolve the medication in the child's milk.
   c. Place a pill in the posterior part of the pharynx and tell the child to swallow.
   d. Check with the prescriber to see if an alternative form can be used.
3. The nurse is caring for an infant who weighs 8.2 kg and is NPO and receiving IV fluid therapy. What rate does the nurse calculate as meeting the child's daily fluid requirements?
   a. 82 mL/hour
   b. 41 mL/hour
   c. 34 mL/hour
   d. 22 mL/hour
4. When administering ear drops to a 2-year-old, which action would be most appropriate?
   a. Tell the child that the drops are to treat his infection.
   b. Pull the pinna of the child's ear down and back.
   c. Have the child turn his head to the opposite side after giving the drops.
   d. Massage the child's forehead to facilitate absorption of the medication.

CRITICAL THINKING EXERCISES

1. When reviewing the medical record of a child, the nurse notes that the ordered dose of medication is different from the recommended dose. How should the nurse proceed?
2. While caring for a 5-year-old child who is receiving IV fluid therapy at a rate of 100 mL/hour, the nurse notes that the infusion is running slowly. The insertion site appears slightly reddened and swollen. What should the nurse do next?
3. A school-aged child is to be discharged, continuing TPN therapy at home. The child lives with his parents and two younger siblings. How would the nurse prepare this child and family for discharge? How could the nurse promote growth and development for this child during TPN therapy?

STUDY ACTIVITIES

1. Review the medical records of several children who are on a pediatric unit in your agency. Note the type of medication, route ordered, and what specific interventions are needed for each child related to the medication administration and developmental age of the child. Compile a list of the most commonly used routes.
2. Interview several parents about their experiences in giving medications to their children. From these interviews, develop a teaching sheet that provides tips to facilitate oral medication administration to children.
3. Create a chart that compares and contrasts the subcutaneous, intramuscular, and intravenous methods of medication administration. Include examples of medications given via these routes, onset of action, appropriate sites, and necessary safety measures for each.
4. An infant is to receive intermittent gavage feedings via a nasogastric tube every 6 hours. The feeding tube was inserted with a previous feeding and remains in place. The nurse is preparing to administer the next scheduled feeding. Place the events in the proper sequence.

   _____ a. Check the placement of the feeding tube.
   _____ b. Position the infant on his right side with the head of the bed slightly elevated.
   _____ c. Allow the feeding to come to room temperature.
   _____ d. Flush the tube with water.
   _____ e. Clamp the tube to prevent air from entering the stomach.
   _____ f. Pour the solution into the barrel of the syringe.

CHAPTER 35

Pain Management in Children

KEY TERMS

acute pain
chronic pain
conscious sedation
drug tolerance
epidural
neuromodulators
neuropathic pain
nociceptive pain
nociceptors
pain
pain threshold
patient-controlled analgesia (PCA)
physical dependence
somatic pain
transduction
visceral pain

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Identify the major physiologic events associated with the perception of pain.
2. Discuss the factors that influence the pain response.
3. Identify the developmental considerations of the effects and management of pain in the infant, toddler, preschooler, school-age child, and adolescent.
4. Explain the principles of pain assessment as they relate to children.
5. Understand the use of the various pain rating scales and physiologic monitoring for children.
6. Establish a nursing care plan for children related to management of pain, including pharmacologic and nonpharmacologic techniques and strategies.

Aiden Russell is a 6-year-old on the pediatric unit admitted for a wound infection. He requires BID dressing changes. In report you are told that Aiden cries and fights during the dressing change but otherwise seems to be playing and not experiencing much pain. The nurse reporting off states, "Aiden's mother keeps requesting pain medication for Aiden. She states he's complaining of pain most of the time. I'm not sure if I believe her: when I see Aiden, he's playing Nintendo games or watching television and seems to be fine. I've tried to hold off on his pain medication as long as I can."

Wow

All of our patients in pain deserve as much comfort as we can give.

Pain is a highly individualized, subjective experience that can affect any person of any age. It is a complex phenomenon that involves multiple components and is influenced by a myriad of factors. Pain often has been described as a subjective experience that involves both sensory and emotional factors. **Pain** is defined by the International Association for the Study of Pain as "an unpleasant sensory and emotional experience that is associated with actual or potential tissue damage" (IASP, 2007). The cause of pain is related to the disease process, treatment protocols, surgical interventions, or injury to the child. A definition of pain that is commonly used defines pain as whatever the person says it is, existing whenever the person says it does (McCaffery & Pasero, 1999)—that is, pain is present when the person says that it is. The person experiencing the pain is the only one who can identify pain and know what the pain is like.

Pain is a universal experience. The American Pain Society (1995) has labeled it "the fifth vital sign" to emphasize the importance of assessing pain frequently and providing appropriate treatment. The goal is to encourage health care professionals to assess pain every time that temperature, pulse, respirations, and blood pressure are assessed and to institute measures to manage the pain.

Pain affects adults and children alike, but children may lack the verbal capacity to describe their pain accurately. In addition, many caregivers and health care providers have misconceptions about pain in children, it is difficult to assess the complex nature of the pain experience, and limited resources and research are available related to pain relief strategies for children. All this makes pain management a critical element in the plan of care for children.

Pain is a major source of distress for children and their families as well as health care providers. Pain affects children of all ages, even preterm infants. Various national health associations have issued position papers and guidelines related to the need to treat pain and suffering in children. Effective pain management involves initial pain assessment, therapeutic interventions, and reassessment for all children in any health care setting.

Pain in children can result from numerous causes, including procedures, and can lead to serious physical and emotional consequences, such as increased oxygen consumption and alterations in blood glucose metabolism. In addition, the experience of pain early in life may lead to long-term consequences for the child (Young, 2005). Treating pain reduces anxiety during procedures and decreases the need for physical restraints, reduces anxiety regarding subsequent procedures, and prevents short- and long-term consequences of inadequately treated pain, particularly in newborns.

This chapter describes the pain experience in children, including the types of pain, factors influencing pain, and common fallacies and myths associated with pain in children. The nursing process is applied to provide an overview of the care for a child in pain. Various pain management strategies are described, including nonpharmacologic and pharmacologic interventions and measures to address procedure-related and chronic pain.

Physiology of Pain

The sensation of pain is a complex phenomenon that involves a sequence of physiologic events in the nervous system. These events are transduction, transmission, perception, and modulation.

Transduction

Peripheral nerve fibers extend from the spinal cord to various locations in and throughout the body's tissues, such as skin, joints, bones, and membranes covering the internal organs. At the end of these fibers are specialized receptors, called **nociceptors**, that become activated when they are exposed to noxious stimuli. The noxious stimuli can be mechanical, chemical, or thermal. Mechanical stimuli may include intense pressure to an area, a strong muscular contraction, or extensive pressure due to muscular overstretching. Chemical stimulation may involve the release of mediators, such as histamine, prostaglandins, leukotrienes, or bradykinin, as a response to tissue trauma, ischemia, or inflammation. Thermal stimuli typically involve extremes of heat and cold. This process of nociceptor activation is called **transduction**.

Transmission

When nociceptors are activated by noxious stimuli, the stimuli are converted to electrical impulses that are relayed along the peripheral nerves to the spinal cord and brain. Specialized afferent nerve fibers are responsible for moving the electrical impulse along. Myelinated A-delta fibers are large fibers that conduct the impulse at very rapid rates. The pain transmitted by these fibers is often referred to as fast pain, most commonly associated with mechanical or thermal stimuli (Porth, 2004). Pain also is transmitted by unmyelinated small C fibers. These fibers transmit the impulse slowly and are often activated by chemical stimuli or continued mechanical or thermal stimuli (Porth, 2004). These fibers carry the impulse to the spinal cord via the dorsal horn. Neurotransmitters are released to facilitate the transmission process to the brain.

Several theories have been proposed in an attempt to explain the process of pain transmission. The best known of these is the gate-control theory. According to this theory, the dorsal horn of the spinal cord contains interneuronal or interconnecting fibers. These fibers, when stimulated, close the gate or pathway to the brain, thereby inhibiting or blocking the transmission of the pain impulse. Subsequently, the impulse does not reach the brain where it would be interpreted as pain.

Perception

Once in the dorsal horn of the spinal cord, the nerve fibers divide and then cross to the opposite side and rise upward

to the thalamus. The thalamus responds quickly and sends a message to the somatosensory cortex of the brain, where the impulse is interpreted as the physical sensation of pain. The impulses carried by the fast pain A-delta fibers lead to the perception of sharp, stabbing, localized pain that also commonly involves a reflex response to withdraw from the stimulus. The impulses carried by the slow C fibers lead to the perception of diffuse, dull, burning, or aching pain. The point at which the person first feels the lowest intensity of the painful stimulus is termed the **pain threshold** (Fig. 35.1). In addition to sending a message to the cerebral cortex, the thalamus also sends a message to the limbic system, where the sensation is interpreted emotionally, and to the brain stem centers, where autonomic nervous system responses begin.

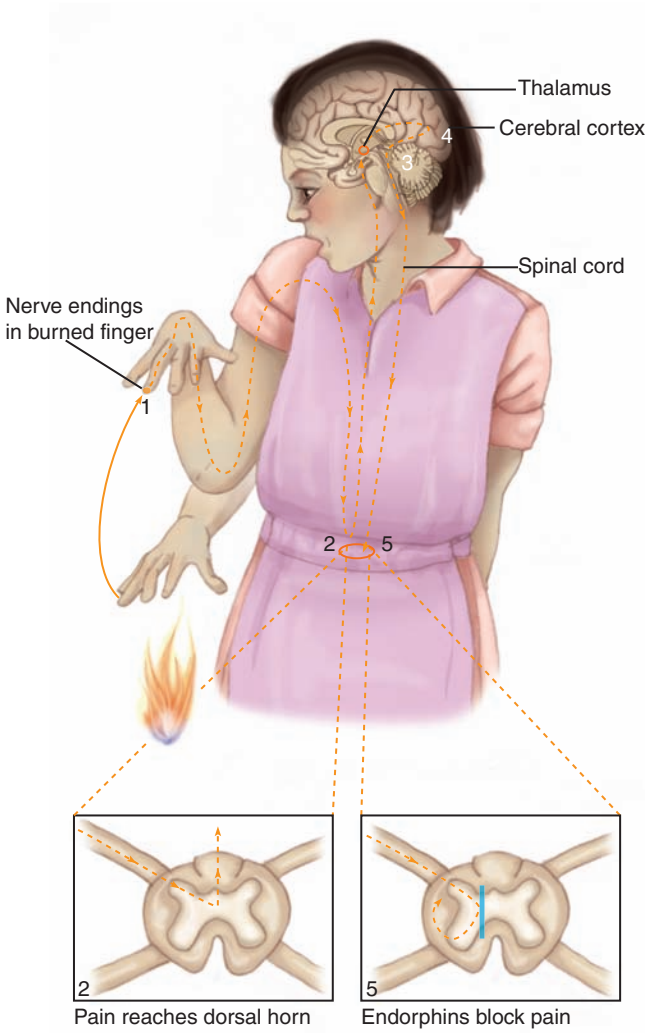

FIGURE 35.1 Physiology of pain: (1) Exposure to thermal noxious stimuli results in activation of nociception (transduction). (2) Impulses are relayed along the peripheral nerves to the spinal cord through the dorsal horn (transmission). (3 & 4) This results in the individual feeling the sensation of pain (perception). (5) Neurons in the brain stem send signls back down to the dorsal horn, and these fibers release substances such as endorphins, which can inhibit painful impulses in the dorsal horn. These neurotransmitters are taken back by the body, therefore limiting the analgesic value.

Modulation

Research has identified substances called **neuromodulators** that appear to modify the pain sensation. These substances have been found to change a person's perception of pain. Examples of these neuromodulators include serotonin, endorphins, enkephalins, and dynorphins.

Pain perception can be modified peripherally or centrally. In the peripheral nerve fibers, chemical substances are released that either stimulate the nerve fibers or sensitize them. Peripheral sensitization allows the nerve fibers to react to a stimulus that is of lower intensity than would be needed to cause pain. As a result, the person perceives more pain. Actions that block or inhibit the release of these substances can lead to a decrease in pain perception.

Modification of pain perception can occur centrally in the spinal cord at the dorsal horn. Substances released by the excited interneurons can potentiate the pain sensation. Other neurochemicals, through their binding to specific receptors, can inhibit the perception of pain.

Types of Pain

Many different systems can be used to classify pain. Most commonly, pain is classified based on its duration, etiology, or source or location.

Classification by Duration

Pain is classified by duration as acute or chronic. **Acute pain** is defined as pain that is associated with a rapid onset of varying intensity. It usually indicates tissue damage and resolves with healing of the injury. Acute pain reflects stimulation of nociceptors and serves a protective function (that is, alerting the person to a problem). Examples of causes of acute pain include trauma, invasive procedures, acute illnesses such as sore throat or appendicitis, and surgery. For example, a child may experience acute pain after operative procedures, trauma, or disease. This type of pain generally last a few days.

▶ ***Take*** NOTE!

Children often experience pain associated with various procedures done in health care settings. This type of pain is usually short in duration. Preparation of the child and family will help to decrease fears or anxiety. Depending on the type of procedure and the child's age, cognitive level, and temperament, various techniques and methods can be used. Advocating for atraumatic care and adhering to its guidelines will help to minimize procedure-related pain.

Chronic pain is defined as pain that continues past the expected point of healing for injured tissue. It provides no protective function. It may be continuous or intermittent, with and without periods of exacerbation or remission. It often interferes with sleep and performance of activities of daily living, thus impairing a person's ability to function. Environmental and affective factors can exacerbate and perpetuate chronic pain, leading to disability and maladaptive behavior (American Pain Society, 2006). Examples of causes of chronic pain include malignant conditions, arthritis, and fibromyalgia.

Chronic pain may be further classified as malignant pain (also called cancer pain, which is associated with cancer or other potentially life-threatening conditions) and chronic non-cancer pain. Malignant pain may be due to the disease itself or its effects on the body or the procedures and treatments used. Chronic non-cancer pain may be the result of numerous conditions, such as juvenile idiopathic arthritis, multiple sclerosis, chronic pancreatitis, or inflammatory bowel disease.

In children, chronic, recurrent pain is most commonly associated with abdominal pain, headache, limb pain, or chest pain, with only a small percentage of this pain found to have an organic etiology (Behrman, 2004). The signs and symptoms that indicate a possible organic etiology include constant pain, pain that wakes the child from sleep, well-localized pain, and other physical findings such as fever, weight loss, changes in color, consistency, or frequency of stools, and urinary tract symptoms (Behrman, 2004). This type of pain lasts for longer periods of time or comes and goes over a period of time.

Classification by Etiology

Pain can be classified by etiology as nociceptive or neuropathic. **Nociceptive pain** reflects pain due to activation of the A-delta fibers and C fibers by noxious stimuli. The pain perceived often correlates closely with the degree or intensity of the stimulus and the extent of real or possible tissue damage (American Pain Society, 2006). With nociceptive pain, nervous system functioning is intact. Reports of nociceptive pain vary depending on the location of the nociceptors being stimulated, ranging from a sharp or burning, to dull, aching, or cramping, to deep aching or sharp stabbing. Examples of conditions that result in nociceptive pain include chemical burns, sunburn, cuts, appendicitis, and bladder distention.

Neuropathic pain is pain due to malfunctioning of the peripheral or central nervous system. It may be continuous or intermittent and is commonly described as burning, tingling, shooting, squeezing, or spasm-like pain. Examples of neuropathic pain include neuropathies, phantom limb pain, and post-stroke pain.

Classification by Source or Location

Pain also may be classified, by the source or location of the area involved, as somatic pain (superficial and deep) or visceral pain. These classifications typically indicate nociceptive pain. **Somatic pain** refers to pain that develops in the tissues. It can be further divided into two groups: superficial and deep. Superficial somatic pain, often called cutaneous pain, involves stimulation of nociceptors in the skin, subcutaneous tissue, or mucous membranes. Typically the pain is well localized and described as a sharp, pricking, or burning sensation. Superficial somatic pain may be due to external mechanical, chemical, or thermal injury or skin disorders. Tenderness commonly is present. The individual also experiences hyperalgesia (an increased response to noxious stimulus) and allodynia (a painful response to a normally nonpainful or non-noxious stimulus; American Pain Society, 2006).

Deep somatic pain typically involves the muscles, tendons, joints, fasciae, and bones. It can be localized or diffuse and is usually described as dull, aching, or cramping. Deep somatic pain may be due to strain from overuse or direct injury, ischemia, and inflammation. Tenderness and reflex spasm may be present. Additionally, the person may exhibit sympathetic nervous system activation such as tachycardia, hypertension, tachypnea, diaphoresis, pallor, and pupillary dilation.

Visceral pain is pain that develops within organs such as the heart, lungs, gastrointestinal tract, pancreas, liver, gallbladder, kidneys, or bladder. It can be well or poorly localized and is described as a deep ache or sharp stabbing sensation that may be referred to other areas. Visceral pain may be due to distention of the organ, organ muscular spasm or pulling, ischemia, or inflammation. Tenderness, nausea, vomiting, and diaphoresis may be present.

Factors Influencing Pain

Children, like adults, experience neurologic events that result in the perception of pain. However, research has found that environmental and psychological factors may exert a greater influence on the child's perception of pain. Certain factors such as age, gender, cognitive level, temperament, previous pain experiences, and family and cultural background cannot be changed. However, situational factors involving behavioral, cognitive, and emotional aspects can be modified. These situation-specific factors that affect the child's pain experience include "what the child and parents understand, what they and the health care staff do, and how the child and parents feel. Certain situational factors can intensify pain and distress, whereas others can eventually trigger pain episodes, prolong pain-related disability, or maintain the repeated pain episodes in recurrent pain syndrome" (McGrath, 2005).

Age and Gender

Research has demonstrated that the nervous system structures needed for pain impulse transmission and perception are present by the 23rd week of gestation (Blount, Piira, Cohen, & Cheng, 2006). Therefore, children of any age, including preterm newborns, are capable of experiencing pain. Early on, children can interpret pain as an unpleasant sensation, but this interpretation is based on their comparison with other sensations. As they get older, they learn to use words to describe their pain more fully.

Gender also may play a role in a child's perception of pain, but research has failed to yield concrete evidence supporting it.

Cognitive Level

Cognitive level is a key factor affecting a child's pain perception and response and usually goes hand in hand with the child's age. Cognitive level typically increases with age, thereby influencing the child's understanding of the pain and its impact and his or her choices for coping strategies. In addition, as the child's cognitive level increases, his or her ability to communicate information about pain increases. However, this increased understanding and ability to communicate with advancing age may not apply to the child experiencing developmental delays. For example, a developmentally delayed school-aged child or adolescent may have the cognitive level of a toddler or preschooler. Health care providers need to be cognizant of this difference when caring for the child in pain. Numerous research studies have revealed that young children often describe pain in concrete terms, whereas older children use more abstract terms that involve both physical and psychological components (McGrath, 2005).

Temperament

Temperament affects how a child will respond to a situation. Previous experience with a situation or the method used to cope with a new or a threatening or harmful situation along with the child's coping style will affect the child's pain experience. Even mild symptoms of negative mood may affect the perceptions and persistence of pain (Palermo et al., 2005). A child with a "difficult temperament" is more likely to have an increased response to pain.

Previous Pain Experiences

A child identifies pain based on his or her experiences with pain in the past. The number of episodes of pain, the type of pain, the severity or intensity of the previous pain experience, and how the child responded all affect how the child will perceive and respond to the current experience. For example, several research studies have demonstrated that children who had negative experiences with pain involving a routine blood-drawing procedure exhibited an increase in anxiety and stress and greater pain when faced with the procedure again.

Family and Culture

The child's cultural and family background will influence how he or she will express and manage pain. Some cultures transmit the standard of accepting pain stoically; others allow outward expression. The parents have a strong influence on the child's ability to cope. For example, if a parent reacts to the child's pain in a positive manner and offers comfort measures, the child may have an easier time coping. If the parent shows anger or disapproval, the pain experience may be intensified for the child.

Situational Factors

Situational factors involve factors or elements that interact with the child and his or her current situation involving the experience of pain. These factors are highly variable and dependent on the specific situation. Examples of situational factors are highlighted in Table 35.1.

Developmental Considerations

Since children of various developmental ages respond differently to pain and perceive pain in different ways, it is important to review developmental considerations. Refer to Chapters 25 through 29 for a more complete understanding of childhood development. Nurses must understand how children of various ages respond to painful stimuli and what behaviors may be expected based on their developmental level. By understanding these developmental considerations, the nurse can appropriately assess the child's pain and provide effective interventions.

Infants

Research has demonstrated that infants, including preterm infants, experience pain and can distinguish pain from other tactile experiences (McGrath & Hillier, 2003). Much of this research focuses on pain related to invasive procedures, such as heelsticks and intravenous catheter insertion. Research suggests that neonates, especially preterm infants, actually experience pain at a greater intensity than children and adults (Gerik, 2005). The belief is related to the immaturity of the inhibitory mechanisms that develop higher in the central nervous system at a later time during fetal development. These mechanisms are more complex and do not become functional until later in gestation.

In preterm and term newborns, behavioral and physiologic indicators are used for determining pain. Behavioral indicators include facial expression, body movements, and crying. Physiologic indicators include changes in heart rate, respiratory rate, blood pressure, oxygen saturation levels, vagal tone, palmar sweating, and plasma cortisol or

TABLE 35.1 SITUATIONAL FACTORS AFFECTING A CHILD'S PAIN EXPERIENCE

Cognitive	Behavioral	Emotional
Information about condition and pain problem, including cause and prognosis	Distress responses; specific behaviors and actions	Anticipatory anxiety
Knowledge about available therapy	Use of therapies	Heightened distress; feelings about scheduled possibly painful treatments
Expectations about the effectiveness of therapy and about the future	Child's or family's response to pain condition	Fear about undiagnosed condition and continuing pain; impact of pain and illness on family
Ability to identify pain triggers	Resolution of stressful situation	Situation-specific stress such as school, sports
Knowledge about stress reduction	Participation in routine activities	Frustration related to interruption in activities
		Underlying anxiety and depression

Adapted from McGrath, P. A., & Hillier, L. M. (2003). Modifying the psychologic factors that intensify children's pain and prolong disability. In N. L. Schecter, C. B. Berde, & M. Yaster, *Pain in infants, children, and adolescents* (2nd ed., Fig. 6.1, p. 87). Philadelphia: Lippincott Williams & Wilkins.

catecholamine levels (American Academy of Pediatrics and Canadian Paediatric Society, 2006).

In the younger infant, facial expression is the most common response to pain (Fig. 35.2). The brows may be lowered and drawn together, with the eyes tightly closed. The mouth is open, often forming a square. The body may be stiff, and thrashing may be seen. When the area is stimulated, the infant may demonstrate a generalized reflex withdrawal. The infant may exhibit a high-pitched, shrill cry.

FIGURE 35.2 In the younger infant, facial expression is the most common response to pain.

The older infant often displays similar behavioral manifestations of pain. The older infant may display an angry facial expression, but the eyes are open. He or she often demonstrates a definite withdrawal response when the area is stimulated. The older infant cries loudly and tries to push away the stimulus that is causing the pain. Other manifestations include irritability, restless sleeping, and poor feeding.

▶ ***Take*** *NOTE!*

Although an infant usually exhibits typical behaviors indicating pain, absence of these manifestations does not indicate a lack of a pain; the response to pain is highly variable.

Infants are preverbal, so facial expression, diffuse body movements, and other signs, as indicated above, provide helpful feedback that the infant is in pain.

Infants also demonstrate physiologic responses to pain. These may include:

- Increased heart rate, usually averaging approximately 10 beats per minute; possibly bradycardia in preterm newborns
- Decreased vagal tone
- Decreased oxygen saturation
- Palmar or plantar sweating (as measured by skin conductivity testing); not reliable in infants under 37 weeks' gestation

Research has identified some short- and long-term consequences of inadequately treated pain in newborns (Paediatrics and Child Health Division, 2006). These include hyperalgesia around a wound from such situations

as repeated heelsticks; an increased risk of developing intraventricular hemorrhage with repeated painful stressors; and a change in the pattern of response to subsequent pain. Children's memories of painful experiences can have long-term consequences for their reaction to later painful events and their acceptance of later health care interventions (von Baeyer et al., 2004). Moreover, preterm infants may be at greater risk for experiencing memories of pain due to the often long hospitalizations involving numerous invasive and painful procedures (Johnston et al., 2003).

Toddlers

Toddlers can react to painless procedures as intensely as painful ones, with intense emotional upset and physical resistance or aggression (Hockenberry et al., 2005). They may bite, hit, scream, or kick. Other behaviors may include being very quiet, pointing to where it hurts, or saying such words as "owww." Facial grimacing and teeth clenching may be noted. They may also react with fear and try to hide or leave the room. They often have limited vocabularies, so it may be difficult for them to express pain. Toddlers may demonstrate regressive behaviors, such as clinging to the parent or crying loudly.

Preschoolers

Since preschoolers may differentiate poorly between their self and the external world, the physical and verbal aggression is more goal-directed. They also may become quiet or try to withdraw and hide: the child may say he or she needs to go to the bathroom or needs to get something from another room. Because of their magical type of thinking, preschoolers may believe pain is a punishment for misbehaving or having bad thoughts. Preschoolers may not verbally report their pain, thinking that pain is something to be expected or that the adults are aware of their pain. They can tell someone where it hurts and can use various tools to describe the severity of pain; however, because they may have limited experience with pain, they may have difficulty distinguishing between types of pain (sharp or dull), describing the intensity of the pain, and determining whether the pain is worse or better.

School-Age Children

School-age children can communicate the type, location, and severity of pain. Children over the age of 8 years can use specific words, such as "sharp as a knife," burning, or pulling, to describe their pain. However, they may deny pain in an attempt to appear brave or to avoid further pain related to a procedure or intervention. They may be more concerned with their fear about the illness and its effects rather than the pain. They also may fear being embarrassed by acting-out behaviors. Thus, a typical response might be to withdraw by staring at the television. Other behaviors may include muscular rigidity, such as clenching the fists, stiffening the body, closing the eyes, wrinkling the forehead, or gritting the teeth.

Adolescents

Adolescents are concerned primarily about body image and fear losing control over their behavior. This may result in denial or refusal of medications. Their mood and what they think is expected of them will also affect their response. Adolescents often ask numerous questions and pay close attention to how others respond to them. Fearing that their behavior may be viewed as juvenile, they may attempt to remain stoic, not exhibiting any emotion. Subtle changes such as increased muscle tension with clenched fists and teeth, rapid breathing, and guarding the affected body part may occur. They may also show lack of interest in everyday activities or a decreased ability to concentrate.

Common Fallacies and Myths About Pain in Children

In general, children respond to pain based on the type of pain, the extent of pain, and their age and developmental level. Table 35.2 highlights some common myths and misconceptions related to pain in children. Because of these myths, children have been medicated less than adults with a similar diagnosis, leading to inadequate pain management.

NURSING PROCESS OVERVIEW FOR THE CHILD IN PAIN

WATCH & LEARN

Nursing care of the child with pain includes nursing assessment, nursing diagnosis, planning, interventions, and evaluation. Each step of this process must be individualized for each patient. A general understanding of the physiology of pain, factors that influence pain, and effective pain management techniques can help to individualize the child's plan of care.

Assessment

Assessment of pain in children consists of both subjective and objective data collection. The acronym **QUESTT** is an excellent way to remember the key principles of pain assessment (Baker & Wong, 1987):

- **Question** the child.
- **Use** a reliable and valid pain scale.
- **Evaluate** the child's behavior and physiologic changes to establish a baseline and determine the effectiveness of the intervention. The child's behavior and motor activity may include irritability and protection as well as withdrawal of the affected painful area.
- **Secure** the parent's involvement.
- **Take** the cause of pain into account when intervening.
- **Take** action.

TABLE 35.2 MYTHS AND MISCONCEPTIONS ABOUT CHILDREN AND PAIN

Myth or Misconception	Fact
Newborns do not feel pain.	Newborns, including preterm newborns, do feel pain. The neurologic and hormonal systems needed for the transmission of painful stimuli are sufficiently developed.
Exposure to pain at an early age has little to no effect on the child. Infants and small children have little memory of pain.	Prolonged or severe pain can lead to increased newborn morbidity. Infants who have experienced pain during the neonatal period respond differently to subsequent painful events (McGrath, 2005). Repeated exposure to painful procedures and events can have long-term consequences. Memories of pain may be stored in the child's nervous system, influencing later reactions to painful stimuli (Johnston et al., 2003).
The intensity of a child's behavioral reaction indicates the intensity of the child's pain.	Numerous factors affect a child's response to pain. Each child is an individual, with his or her own set of responses.
A child who is sleeping or playing is not in pain.	Sleep or play may be a coping strategy for the child in pain. Sleep may reflect exhaustion of the child who is coping with pain.
Children are truthful when they are asked if they are experiencing pain.	Often children deny pain to avoid a painful situation or procedure, embarrassment, or loss of control. Children may assume that others know how they are feeling and thus will not verbalize their complaints.
Children learn to adapt to pain and painful procedures.	Repeated exposure to pain or painful procedures can result in an increase in behavioral manifestations.
Children experience more adverse effects of narcotic analgesics than adults do.	The risk of adverse effects of narcotic analgesics is the same for children as for adults.
Children are more prone to addiction to narcotic analgesics.	Addiction to narcotics when used in children is very rare.

▶ ***Take*** *NOTE!*

Children do experience pain, and pain management techniques work just as well with children as they do with adults.

Health History

When assessing pain in children, tailor the assessment to the child's developmental level and ask questions geared to the child's cognitive ability. During the health history, determine the child's previous exposure to pain, if any, and how the child responded. This information will provide clues about how the child copes and his or her current response. Attempt to determine what word the child uses to denote pain. Some children may not understand the term "pain" but do understand terms such as "ouchie" or "boo-boo."

The health history also includes questioning the parents about their cultural beliefs related to pain and their child's usual responses. This information aids in planning developmentally and culturally appropriate family-centered care.

Questioning the Child

When questioning the child, phrase the questions in a manner that the child will be able to understand based on his or her developmental level. Some input from the child's family may be helpful in determining where best to focus the questions.

Ask the child what pain means to him or her. Use words that the child may comprehend more easily, such as "hurt," "boo-boo," or "ouch," as appropriate. Inquire about similar experiences in the past and how he or she responded. Determine whether the child let others know that he or she was hurting and how this message was conveyed (e.g., crying, acting out, or pointing to the hurting area).

Review the history of the pain and various influences such as cultural aspects, caregiver attitudes or expectations, previous experiences, and any education or teaching related to pain management. Continue to formulate questions to ascertain the following:

- Location, quality, severity, and onset of the pain, as well as the circumstances in which the child experiences the pain. Have the child point to the area where it hurts or identify the location on a diagram or doll.
- Conditions, if any, that preceded the onset of pain and the conditions that followed the onset of pain
- Any associated symptoms, such as weight loss, fever, vomiting, or diarrhea, which may indicate a current illness
- Any recent trauma, including any interventions that were used in an attempt to relieve the pain

Continue the health history by inquiring about what the child wants others, including the nurse, to do when the child hurts. Conversely, ask the child what he or she doesn't want others to do. Finally, question the child about measures that seem to be most effective in relieving the pain. Ask if there is anything special the child wants to tell the nurse, such as a special pain-relief technique or a specific comfort object.

If the child is experiencing chronic or recurrent pain, suggest the child and family record information in a symptom diary. Explain that this will be helpful in identifying the best ways to manage the pain.

Questioning the Parents

Parents play a key role in assessing pain in children. Often it is the parents who provide information about the child's current and past experiences with pain. In addition, parents can provide information about how the child exhibits and responds to pain. Parents may be aware of subtle changes in the child's behavior that may precede the pain, occur with the pain, or indicate relief of pain. Including the parents in this process helps create a positive experience for all involved and promotes feelings of control over the situation.

The questions posed to the parents are similar in focus to those posed to the child. However, more detailed information may be obtained from the parents because they are usually able to describe events more fully or in greater detail due to their higher cognitive level. Parents typically know their child best.

▶ *Take* NOTE!

Parents may assume that nurses have greater expertise when it comes to assessing their child's pain and taking appropriate action. Thus, they may not always report when they notice changes suggesting that their child is uncomfortable. Emphasize the important role that parents play in reporting any changes in their child so that pain relief measures can be instituted as soon as possible.

When questioning the parents, use the following examples as a guide for assessing the child's pain:

- Has your child ever been in pain before? If so, what was the cause of the pain? How long did he or she have the pain? Where was the pain located?
- How did your child react to the pain? What did you do to lessen the pain?
- Did your child let you know that he or she was in pain? Did he or she tell you or did you notice something?
- Are there any special signs that let you know that your child is hurting? If so, what are they?
- Is there anything that your child does or that you do when he or she is hurting that helps relieve the pain?
- Does one thing work better than another when your child is hurting?
- Is there any special information that you want to tell me about your child?

Using Pain Rating Scales

Various pain assessment or pain rating scales are available. These scales allow the child to report his or her pain, and the pain level is quantified. These standardized rating scales provide a greater alignment between the child's pain and the nurse's assessment of the severity of the pain.

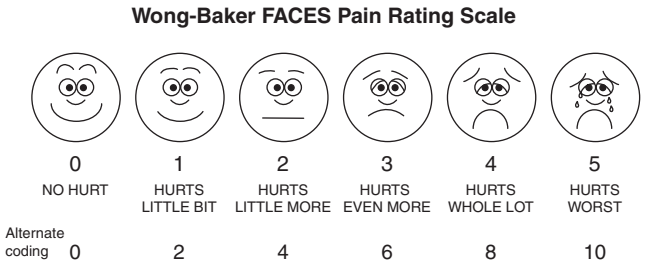
Many health care facilities have specific policies and procedures related to pain assessment, including the frequency of assessment, the rating tool to use, and nursing interventions to be instituted based on the rating. For example, many facilities require assessment of the child using a specific tool with documentation at least once a shift and 30 minutes to 1 hour after a non-pharmacologic or pharmacologic pain-relief intervention. This process provides a more objective method to determine whether the pain is increasing or decreasing and whether pain-relief methods are effective.

▶ *Take* NOTE!

Typically, different pain rating scales are appropriate for different developmental levels. However, children may regress when in pain, so a simpler tool may be needed to make sure that the child understands what is being asked. Regardless of the tool used, nurses need to be consistent in using the same tool so that appropriate comparisons can be made and effective interventions can be planned and implemented. Using the most appropriate tool consistently allows the most accurate assessment of the child's pain.

FACES Pain Rating Scale. The FACES pain rating scale (Fig. 35.3) is a self-report tool that can be used by children as young as 3 years of age. The scale consists of six illustrations of faces arranged horizontally with expressions ranging from smiling (indicating no hurt) to crying with frowning (indicating hurts worst). Under each face is a short description such as "hurts little bit" and a number. The number scale can be 0, 1, 2, 3, 4, and 5 or 0, 2, 4, 6, 8, and 10. The nurse explains the words associated with each face. Then the child is asked to select the facial expression that best describes how he or she is feeling. The nurse then documents the number corresponding to the word description and face.

Oucher Pain Rating Scale. The Oucher pain rating scale is similar to the FACES scale in that it uses facial expressions to indicate increasing degrees of hurt. However,



Instructions: Explain to the person that each face is for a person who feels happy because he has no pain (hurt) or sad because he has some or a lot of pain. **Face 0** is very happy because he doesn't hurt at all. **Face 1** hurts just a little bit. **Face 2** hurts a little more. **Face 3** hurts even more. **Face 4** hurts a whole lot. **Face 5** hurts as much as you can imagine, although you don't have to be crying to feel this bad. Ask the person to choose the face that best describes how he is feeling.

FIGURE 35.3 FACES Pain Rating Scale. (From Hockenberry, M. J., Wilson, D., & Winkelstein, M. L. [2005]. *Wong's essentials of pediatric nursing* [7th ed., p. 1259]. St. Louis, MO. Used with permission. Copyright, Mosby.)

instead of illustrations, six photographs are used: "no hurt" is placed at the bottom of the arrangement and "most hurt" at the top. Alongside the photos is a scale ranging from 0 to 10 that corresponds to the facial expressions in the photographs (Fig. 35.4). After explaining the photos and numeric scale, the child is asked to point to the number that best describes his or her level of pain.

This scale is useful for self-reporting of pain in children from 3 to 13 years of age. Three different scales have been developed for use with Caucasian, Hispanic, and African-American children.

FIGURE 35.4 Oucher Pain Rating Scale.

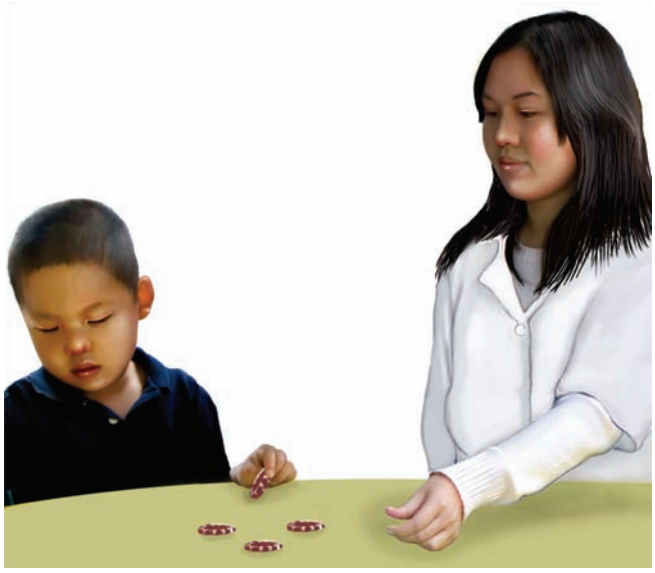


FIGURE 35.5 The poker chip tool. Here the nurse asks the child to identify the number of chips that indicate her degree of "hurt."

Poker Chip Tool. The poker chip tool is a self-reporting pain assessment tool that uses four red poker chips to quantify the child's level of pain. The chips are arranged in a horizontal line on a surface in front of the child. Starting with the chip closest to the child's left side, the nurse points to the chip and explains that the first chip means a little hurt, the next chip means more hurt, the third chip means more hurt, and the fourth chip means the worst hurt ever. Then the nurse asks the child how many "pieces of hurt" he or she is having (Fig. 35.5). If the child is not experiencing any pain, typically the child will state that he or she isn't having any. When the child identifies the number of "pieces of hurt," the nurse follows up by asking the child to tell the nurse more about his or her hurt.

The poker chip tool is useful for assessing pain in children who are 4 years of age or older. Children may view this assessment tool as a game since it involves poker chips. However, the nurse needs to ensure that the child has the cognitive ability to distinguish the numbers.

Word-Graphic Rating Scale. The word-graphic rating scale is a self-reporting scale that consists of a line with descriptors underneath: no pain, little pain, medium pain, large pain, and worst possible pain (Fig. 35.6). The nurse explains the line and descriptors to the child. Then

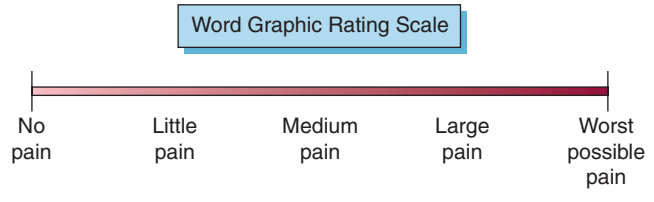

FIGURE 35.6 Word-graphic rating scale.

the child is asked to make a vertical mark on the horizontal line at the point that best describes the child's level of pain. The nurse uses a ruler to measure the distance from the "no pain" starting point to the area marked by the child. This measurement is recorded as the pain score. The word-graphic rating scale is useful for children 4 to 17 years old.

Visual Analog and Numeric Scales. Visual analog and numeric scales involve a horizontal or vertical line with marked endpoints. With a visual analog scale, the end points are identified as no pain and worst pain. A numeric scale typically has endpoints of 0 and 10, reflecting no pain and worst pain, respectively (Fig. 35.7). The nurse explains the scale to the child. With the visual analog scale, the child makes a line that best describes the level of pain. The nurse then measures the distance from the "no pain" endpoint to the child's mark and records this as the pain score. With the numeric scale, the nurse asks the child to pick the number that best describes his or her level of pain.

The numeric scale can be used with children as young as 5 years of age, as long as they can count and understand the concepts related to numeric values. Although research has validated use of the visual analog scale with children as young as 4.7 years of age, the preferred minimum age for using this tool is 7 years (Algren, 2005).

Adolescent Pediatric Pain Tool. The Adolescent Pediatric Pain Tool is a self-report type of tool useful for older children, usually from ages 8 to 17 years. The tool involves three aspects of assessment. In the first assessment the child identifies the location of the pain on two illustrations of the body, front and back views (Fig. 35.8). The child is instructed to color the areas where he or she is hurting. The child is also instructed to color the area as big or as small as how much he or she is hurting. For example, if the hurt is mild or moderate, the child would color a moderate area of the location; if the pain was severe, he or she would color a much larger area. The second portion of the tool involves a scale that ranges from "no pain" to "worst possible pain"; the child is instructed to identify the severity of his or her pain. The third assessment is a list of words that may be used to describe pain, such as throbbing, pounding, stabbing, or sharp. The child is asked to point to or circle the words that describe the current pain. Children with limited reading skills or vocabulary may have difficulty with some of the words listed to describe pain. Work with the child and encourage the parents to help the child understand the various descriptive words. Parental participation fosters control over the situation and gives the parents some insight into what their child is experiencing.

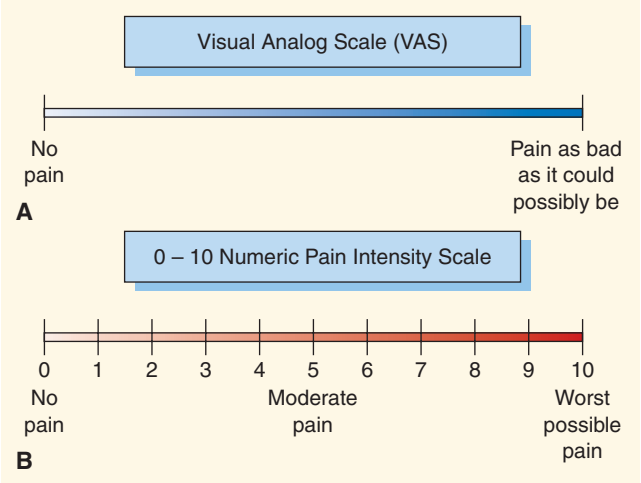

FIGURE 35.7 (**A**) Visual analog scale. (**B**) Numeric scale.

Physical Examination

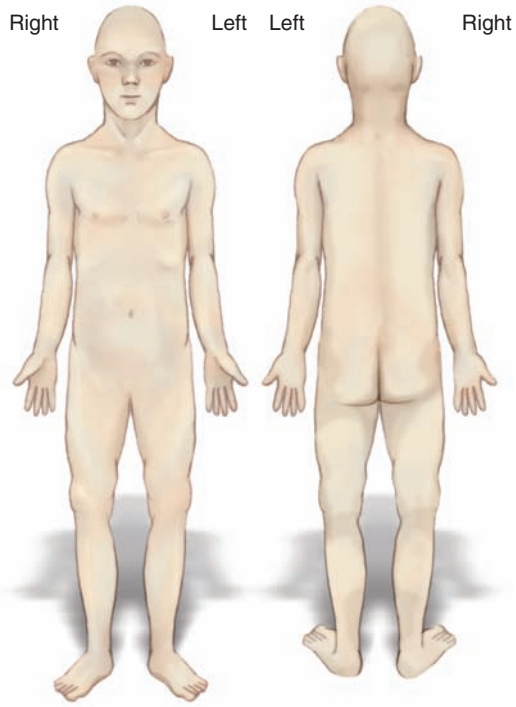
Physical examination of the child for pain primarily involves the skills of observation and inspection. These skills are used to assess for physiologic and behavioral changes that indicate pain. Auscultation also may be used to assess for changes in vital signs, specifically heart rate and blood pressure.

Manifestations of Pain

Observe for physical signs and symptoms of pain, keeping in mind the child's developmental level. Look for facial expressions of discomfort, grimacing, or crying. Be alert for movements that may suggest pain. For example, an infant or toddler may pull on the ear when experiencing ear pain. The child may move the head from side to side, suggesting head pain. Typically, children with abdominal pain will lie on one side and draw their knees up to the abdomen. Inspect the child's gait: a limp or avoidance of weight bearing may suggest leg pain. Immobility, guarding of a particular body area, or refusal to move an area may be observed. Inspect the skin for flushing or diaphoresis, possible indicators of pain. Also monitor vital signs for changes. Pulse or heart rate, respiratory rate, and blood pressure may increase. Other physiologic parameters suggesting pain may include elevated intracranial pressure and pulmonary vascular resistance and decreased oxygen saturation levels.

▶ ***Take*** NOTE!

The body responds to acute pain via the sympathetic nervous system, leading to stimulation and subsequently the increase in vital signs. However, if the child has persistent or chronic pain, the body adapts and these changes may be less noticeable; in fact, heart and pulse rate, respiratory rate, and blood pressure may actually decrease.



Sensory	Affective	Evaluative	Temporal
Aching ("pain all over")	Awful ("cannot do anything")	Annoying ("cannot sleep")	Always ("pain always there")
Hurting ("pain all over")	Crying ("hurts so bad")	Bad ("cannot stop the hurting")	Comes and goes ("always pain")
Sore ("like a cut")	Frightening ("scared it won't stop")	Miserable ("cannot sleep or do stuff")	Comes on all of a sudden ("no warning")
Beating (procedural pain "spots")	Screaming (afraid of "going to the hospital")	Terrible ("don't like it")	Constant ("never goes away")
Pounding ("gets on your nerves")	Terrifying ("cannot sleep," "really tired," "not going to live")	Uncomfortable ("can't stay in one spot")	Continuous ("pain not going away")
Cutting ("hurts more than a cut")		Uncontrollable ("cannot stop it")	Forever ("never will go away")
Like a sharp knife ("stabbing and sharp")	Dizzy ("don't know where I am")		Once in a while ("in a month sometimes pain; sometimes not")
Sharp (no meaning)			Sneaks up ("don't know when the pain will happen")
Stabbing (no meaning)			Sometimes ("goes away sometimes; sometimes not")
Cramping ("everywhere like a plane crash")			
Crushing (no meaning)			
Pressure ("pushing all over")			
Itching ("all over")			
Scratching ("helps sometimes")			
Shocking (pain "surprises" her)			
Splitting ("splitting in half" her body)			
Numb ("knows pain is there"/ procedural pain)			
Stiff ("cannot move")			
Swollen ("meds do not help")			
Tight ("cannot move")			

FIGURE 35.8 Adolescent Pediatric Assessment Tool. (Top) Adolescent Pediatric Pain Tool (APPT): Body Outline (Crandall & Savedra, 2005). (Bottom) Pain Quality: Words chosen and meaning of words (Crandall & Savedra, 2005).

The child also may exhibit behavioral changes indicating pain. Be alert for irritability and restlessness. Watch for clenching of teeth or fists, body stiffening, or increased muscle tension. Note any changes in the child's behavior—for example, a child who previously was talkative and playful who becomes quiet and almost withdrawn. In addition, pay close attention to the child's cultural background and how these beliefs may be affecting the behavioral response to pain.

Each child is an individual with unique responses to pain, so the nurse must ensure that observations of behavior do indeed reflect the child's pain level. To help ensure the accuracy of observations, several physiologic and behavioral assessment tools have been developed to help quantify the observations.

Physiologic and Behavioral Pain Assessment Tools

Use of physiologic and behavioral pain assessment tools allows measurement of specific parameters and changes that would indicate that the child is experiencing pain. These measurements aid in determining the intensity of the pain experience. Along with the self-report pain-rating scales, measurement of these changes allows the nurse to objectively assess pain and the effectiveness of pain management measures.

Neonatal Infant Pain Scale. The Neonatal Infant Pain Scale (NIPS) is a behavioral assessment tool that is useful for measuring pain in preterm and full-term neonates. Six parameters are measured: facial expression, cry, breathing patterns, arms, legs, and state of arousal (Table 35.3). Each parameter except for cry is scored as a 0 or 1; cry is scored as 0, 1, or 2. The scores are totaled; the maximum score that can be achieved is 7. A higher score indicates increased pain. This tool is not recommended for use in neonates who are too ill to respond or who are receiving paralyzing agents. In these cases, a falsely low score would be produced.

Riley Infant Pain Scale. The Riley Infant Pain Scale (RIPS) is a behavioral assessment tool useful for infants who lack verbal ability. Like NIPS, RIPS measures six parameters: facial expression, body movement, sleep, verbal or vocal ability, consolability, and response to movements and touch (Table 35.4). Each parameter is scored as 0, 1, 2, or 3. The score is totaled; the maximum score that can be achieved is 18. The higher the total score, the more intense the pain.

Pain Observation Scale for Young Children. The Pain Observation Scale for Young Children (POCIS) is a behavioral assessment tool designed for use in children 1 to 4 years of age. This tool measures seven parameters: facial expression, cry, breathing, torso, arms and fingers, legs and toes, and state of arousal (Table 35.5). Each parameter is scored as 0 or 1; the maximum score achievable is 7. The higher the score, the greater the pain being experienced by the child.

CRIES Scale for Neonatal Postoperative Pain Assessment. The CRIES scale is a behavioral assessment tool that also includes measures of physiologic parameters. It was developed to quantify postoperative pain in the newborn. The tool also may be used to monitor the infant's progress over time during recovery or after interventions. The tool assesses five parameters: cry, oxygen required for saturation levels less than 95%, increased vital signs, facial expression, and sleeplessness (Table 35.6).

TABLE 35.3 THE NEONATAL INFANT PAIN SCALE (NIPS)

Parameter	Finding	Score
Facial expression	Relaxed (restful face; neutral expression)	0
	Grimace (tight facial muscles; furrowed brow, chin, or jaw; negative facial expression)	1
Cry	No cry (quiet; not crying)	0
	Whimper (mild intermittent moaning)	1
	Vigorous crying (loud screaming, shrill, continuous)	2
Breathing patterns	Relaxed	0
	Change in breathing (irregular; faster than usual; gagging; breath holding)	1
Arms	Relaxed (no muscular rigidity; occasional random movements of arm)	0
	Flexed/extended (tense, straight, rigid, or rapid flexion or extension)	1
Legs	Relaxed (no muscular rigidity; occasional random movements of leg)	0
	Flexed/extended (tense, straight, rigid, or rapid flexion or extension)	1
State of arousal	Sleeping/awake (quiet, peaceful; settled)	0
	Fussy (alert, restless, thrashing)	1

TABLE 35.4 THE RILEY INFANT PAIN SCALE

Parameter	Score
Facial expression	
• Neutral/smiling	0
• Frowning/grimacing	1
• Clenched teeth	2
• Full cry expression	3
Body movement	
• Calm, relaxed	0
• Restless, fidgeting	1
• Moderate agitation or mobility; thrashing, flailing, incessant agitation or strong voluntary mobility	2
• Voluntary immobility	3
Sleep	
• Sleeping quietly with easy respirations	0
• Restless while asleep	1
• Sleeps intermittently (sleep/awake)	2
• Sleeping for prolonged periods of time interrupted by jerky movements or inability to sleep	3
Verbal/vocal	
• No cry	0
• Whimpering, complaining	1
• Pain crying	2
• Screaming, high-pitched cry	3
Consolability	
• Neutral	0
• Easy to console	1
• Not easy to console	2
• Inconsolable	3
Response to movement/touch	
• Moves easily	0
• Winces when touched or moved	1
• Cries out when moved or touched	2
• High-pitched cry or scream when touched or moved	3

From Schade, J. G., Joyce, B. A., Gerkensmeyer, J., & Keck, J. F. (1996). Comparison of three preverbal scales for postoperative pain assessment in a diverse pediatric sample. *Journal of Pain and Symptom Management*, *12*(6), 348–359.

Each parameter is scored as 0, 1, or 2 and then totaled. As with other assessment tools, the higher the score, the greater the infant's pain.

FLACC Behavioral Scale for Postoperative Pain in Young Children. The FLACC behavioral scale is a behavioral assessment tool that is useful in assessing a child's pain when the child cannot report accurately his or her level of pain. It has been demonstrated to be a reliable tool for children from age 2 months to 7 years of age. This tool measures five parameters: facial expression, legs, activity, cry, and consolability (Table 35.7). Observe the child with the legs and body uncovered. If the child is awake, observe

TABLE 35.5 THE PAIN OBSERVATION SCALE FOR YOUNG CHILDREN (POCIS)

Parameter	Finding	Score
Facial expression	Neutral	0
	Grimace (negative)	1
Cry	No cry	0
	Moan, scream	1
Breathing	Relaxed and regular	0
	Irregular and indrawn	1
Torso	At rest, inactive	0
	Tense, shivering	1
Arms and fingers	At rest, inactive	0
	Tense, restless	1
Legs and toes	At rest, inactive	0
	Tense, restless	1
State of arousal	Calm, sleepy	0
	Fussy	1

him or her for 2 to 5 minutes; if sleeping, observe the child for 5 minutes or longer. Each parameter is scored as 0, 1, or 2; the scores are totaled, with a maximum achievable score of 10. As with other assessment tools, the higher the score, the greater the pain.

Nursing Diagnoses, Goals, Interventions, and Evaluation

After the assessment is completed, the nurse identifies appropriate nursing diagnoses. The most commonly identified nursing diagnosis would be Acute or Chronic pain. However, the related factors and defining characteristics can vary widely. Nursing diagnoses will focus on the effects of pain on the child—for example, the stress incurred as a result of the pain or the fear or anxiety associated with the pain or events causing the pain. Moreover, pain can affect physiologic functions, such as sleep, nutrition, mobility, and elimination. Examples of common nursing diagnoses may include:

- Acute pain related to repeated need for invasive procedures, surgical experience, recent trauma, or infection
- Chronic pain related to prolonged illness or injury, effects of cancer on surrounding tissues, or treatment-related effects
- Fear related to the unknown, separation from family, anticipation of invasive procedures, or effects of treatment
- Anxiety related to the stress and uncertainty of the situation
- Deficient knowledge related to current condition and appropriate methods for managing pain
- Disturbed sleep pattern related to inability to manage pain effectively

TABLE 35.6 THE CRIES SCALE FOR NEONATAL POSTOPERATIVE PAIN ASSESSMENT

Assessment	0	1	2
Crying	No	High-pitched, but consolable	High-pitched, inconsolable
Oxygen required for saturation above 95%	No	<30%	>30%
Increased vital signs	Heart rate and blood pressure within 10% of preoperative values	Heart rate or blood pressure 11% to 20% higher than preoperative values	Heart rate or blood pressure 21% or more above preoperative values
Expression	No grimace	Grimace	Grimace with grunt
Sleepless	No	Waking at frequent intervals	Constantly awake
Total infant score			

From Krechel, S. W., & Bildner, J. (1995). CRIES: A new neonatal postoperative pain measurement score. Initial testing of validity and reliability. *Paediatric Anaesthesia, 5,* 53–61.

- Impaired mobility related to increased episodes of pain
- Risk for constipation related to potential adverse effects of narcotic analgesic agents

When caring for a child experiencing pain, the ultimate goal is that the child will be free of pain as evidenced by participation in age-appropriate activities of daily living and vital signs within age-appropriate parameters. However, at times, this may be unrealistic, especially if the child is experiencing chronic pain. Therefore, a more appropriate goal would be that the child reports that his or her pain has decreased to a tolerable level. Pain assessment tools can be used to quantify the amount by which the child's pain has decreased. For example, if the child has rated the pain as 7 out of 10, a realistic goal might be that the child reports a pain rating of no more than 4 out of 10. Additional goals would reflect improvement or resolution of the identified problem. For example, a short-term goal for a child experiencing disturbed sleep due to the pain might be that the child sleeps for a minimum of 4 consecutive hours through the night. A long-term goal might be that the child sleeps for 7 to 8 hours undisturbed through the night.

Various interventions can be used for pain management. These interventions include pharmacologic and nonpharmacologic measures. A guiding principle when caring for the child experiencing pain is the provision of atraumatic care (see Chapters 2 and 34 for more information). For example, apply a topical anesthetic cream to a site early enough before a venipuncture that it becomes effective. Use an intermittent infusion device to obtain multiple blood specimen samples rather than performing repeated venipunctures. Consider the use of sedation

TABLE 35.7 FLACC BEHAVIORAL SCALE

	Scoring		
Category	0	1	2
Face	No particular expression or smile	Occasional grimace or frown, withdrawn, disinterested	Frequent to constant frown, clenched jaw, quivering chin
Legs	Normal position or relaxed	Uneasy, restless, tense	Kicking, or legs drawn up
Activity	Lying quietly, normal position, moves easily	Squirming, shifting back and forth, tense	Arched, rigid, or jerking
Cry	No cry (awake or asleep)	Moans or whimpers, occasional complaint	Crying steadily, screams or sobs, frequent complaints
Consolability	Content, relaxed	Reassured by occasional touching, hugging, or being talked to, distractable	Difficult to console or comfort

Each of the five categories is scored from 0 to 2, which results in a total score between 0 and 10.

for more painful procedures. In addition to pharmacologic measures, cognitive and behavioral approaches are appropriate for pain management, including pain management related to procedures.

Throughout the child's care, be sure to discuss specific goals and interventions with the child and family as appropriate. Include the family in developing appropriate interventions so they can continue to support the child. Education of the child and family about interventions, including various therapies, is key. Play therapy may be helpful in allowing the child to express his or her feelings and adapt to the stressors of the current situation. Ongoing assessment is needed to determine the effectiveness of the pain relief measures in achieving the desired goals.

Nursing Care Plan 35.1 can be used as a guide in planning nursing care for the child experiencing pain. The nursing care plan should be individualized based on the child's symptoms and needs. Specific information related to pain management and the nurse's role will be discussed later in the chapter.

When you enter Aiden's room, he is crying and says his leg hurts. What will be your initial action? What will be your plan of care to manage Aiden's pain (refer to QUESTT assessment)? How would you address the statements made by the nurse in report? What approaches can you use to change staff behavior about pain management?

Management of Pain

Three general principles guide pain management in children:

1. Individualize interventions based on the amount of pain experienced during a procedure and the child's personality.
2. Use nonpharmacologic and pharmacologic approaches to ease or eliminate the pain.
3. Use aggressive pharmacologic treatment with the first procedure.

Strategies for pain management include nonpharmacologic interventions such as distraction, relaxation, and guided imagery and pharmacologic interventions such as analgesics, patient-controlled analgesia, local analgesia, epidural analgesia, and conscious sedation.

Nonpharmacologic Management

Various techniques may be available to assist in managing mild pain in children or augment the effectiveness of medications for moderate or severe pain. Many of these nonpharmacologic techniques assist children in coping with pain and give them an opportunity to feel a sense of mastery or control over the situation. Two types of techniques are behavior/cognitive strategies and biophysical strategies. With these techniques as well as administration of medications, parents need to be involved in the process.

Behavioral–Cognitive Strategies

Behavioral-cognitive strategies for pain management involve measures that require the child to focus on a specific area rather than the pain. These strategies help to change the interpretation of the painful stimuli, reducing pain perception or making pain more tolerable. In addition, these strategies help to decrease negative attitudes, thoughts, and anxieties, thereby improving the child's coping mechanisms. Typically, these interventions work well with older children, but some younger children also benefit from these techniques if they are adapted to the child's age and developmental level. Common behavioral-cognitive strategies include relaxation, distraction, imagery, biofeedback, thought stopping, and positive self-talk.

Relaxation

Relaxation aids in reducing muscle tension and anxiety. A wide variety of techniques can be used. Relaxation can be as simple as holding an infant or young child closely while stroking the child or speaking in a soft soothing manner, or having the child inhale and exhale slowly using rhythmically controlled deep breathing. It also can involve more sophisticated techniques such as progressive relaxation. With this technique the child is asked to focus on one area of the body and let that body part go limp. Then in an organized fashion, usually working from the toes to the head or vice versa, the child is asked to focus on another body part, making it go limp. Eventually the exercises work through all body areas, leading to relaxation of the entire body.

Distraction

Distraction involves having the child focus on another stimulus, thereby attempting to shield him or her from pain. This technique does not eliminate the pain but does help to make it more tolerable. Various methods can be used for distraction, including:

- Counting
- Repetition of specific phrases or words, such as "ouch"
- Listening to music or singing
- Playing games, including computer games
- Blowing bubbles or blowing pinwheels or party favors
- Listening to favorite stories (Fig. 35.9)
- Watching cartoons, television shows, or movies
- Visiting with friends
- Humor

Humor has been demonstrated to be an effective distracting technique for pain management. However, make sure that the technique is age-appropriate and be sure to determine what or who will make the child laugh. If possible, allow the child and his family to choose the materials that they consider humorous.

Nursing Care Plan 35.1

OVERVIEW FOR THE CHILD IN PAIN

NURSING DIAGNOSIS: Acute pain related to need for invasive procedures, surgery, recent trauma, or infection as evidenced by pain rating scale, facial grimacing, crying, irritability, withdrawal activity, or changes in vital signs

Outcome Identification and Evaluation

Child will achieve adequate comfort level as evidenced by a decrease in rating number (3 or less) on a pain rating scale, quietness, calm resting behaviors, decrease in crying and irritability, and vital signs within acceptable parameters.

Intervention: Promoting Pain Relief

- Assess pain level using a developmentally appropriate pain rating tool *to establish a baseline.*
- Assess for verbal and nonverbal indicators of pain; question parents about child's typical behaviors and previous experiences with pain *to determine factors that may be influencing child's response to pain.*
- Institute nonpharmacologic methods for pain control based on the child's age and cognitive level; encourage parental participation in use of methods *to provide additional support for the child.*
- Administer pharmacologic agents as ordered using the least traumatic route possible *to alter pain impulse transmission and minimize distress while promoting effective pain relief.*
- Explain the action of the drug and what the child should expect from the medication at a level that the child can understand *to promote trust and reduce fear.*
- Give analgesics around the clock if pain is continuous and can be predicted *to maintain steady blood levels of the drug, thereby maximizing the drug's effect.*
- Perform atraumatic care at all times *to minimize the child's exposure to physical and psychological distress.*
- If a procedure is to be done, explain the purpose of the medication before the procedure and what to expect *to help minimize fear of the unknown.*
- Anticipate timing of procedures or situations that may lead to pain and provide appropriate analgesic therapy as ordered *to ensure that therapy is most effective at the time of the procedure.*
- Ensure that the child's environment is quiet and conducive to rest, dim the lights, close the door or curtain *to reduce sensory overload that would increase the child's pain sensation.*
- Encourage the parents to stroke, touch, caress, and hold the child *to promote feelings of security.*
- Reassess child's pain level after use of nonpharmacologic and pharmacologic methods *to determine effectiveness*; anticipate the need to modify or adapt nonpharmacologic methods or adjust analgesic dosage, route, or frequency *to promote maximum pain relief.*
- Perform nursing care activities after administering analgesic *to prevent exacerbating the child's pain.*
- Use diversional activities, distraction, and play appropriate to the child's age and cognitive level *to promote additional pain relief.*

NURSING DIAGNOSIS: Anxiety related to stress and uncertainty of the situation, unknown cause of pain, lack of familiarity with procedures, testing, and health care facility, and painful procedures, as evidenced by crying, irritability, withdrawal, stoic or aggressive behaviors

Outcome Identification and Evaluation

Child and family will demonstrate a decrease in anxiety level as evidenced by age-appropriate positive coping behaviors, verbalization of feelings, playing out of feelings, child and family cooperation with plan of care, and absence of signs and symptoms associated with escalating anxiety.

Intervention: Minimizing Anxiety

- Assess child's and parents' understanding of the situation, including their understanding of what may be causing the pain and the reasons for the procedures and testing, *to provide baseline information about the child's and parents' knowledge and possible clues to anxiety.*
- Spend time with the child and parents discussing what they think might be happening, encouraging child and parents to talk openly about their feelings, *to facilitate continued expressions and communication.* Allow time for questions and answer questions honestly *to establish rapport and build trust.*

(continued)

Nursing Care Plan 35.1 (continued)

- Approach the child and family in a calm, relaxed manner *to foster trust and communication.*
- Allow the child options related to pharmacologic agent administration as much as possible, such as fluid to drink or snack to eat, extremity to use for venipuncture (right or left), color of bandage, or holding tape or dressing, *to foster feelings of control.*
- Provide atraumatic care *to reduce exposure to distress, which would exacerbate the child's anxiety level.*
- Explain any procedures, tests, or activities at a level the child can understand *to reduce fear of the unknown.*
- Incorporate aspects of the child's routine at home as much as possible *to reduce feelings of separation and promote feelings of normalcy.*
- Ensure consistency in care *to facilitate trust and acceptance.*
- Encourage parents in the use of comfort measures such as stroking, cuddling, holding, and rocking *to promote feelings of security and minimize stress.*
- Provide positive reinforcement for choices, participation in activities, and use of appropriate coping methods *to foster self-esteem.*
- Encourage the child's participation in play (unstructured and therapeutic play as needed) *to promote expression of feelings and fears.*

NURSING DIAGNOSIS: Deficient knowledge related to current condition and appropriate methods for managing pain as evidenced by crying, irritability, pushing away, questions and verbalizations about pain and relief methods

Outcome Identification and Evaluation

Child and parents will demonstrate adequate knowledge about the child's current condition and use of pain relief methods as evidenced by statements about the cause of the child's pain, demonstration of chosen nonpharmacologic relief methods, use of pharmacologic agents, and statements related to signs and symptoms of increased and decreased pain.

Intervention: Providing Child and Family Teaching

- Assess child's and parents' knowledge and understanding of child's current condition and current pain level *to establish a baseline for teaching.*
- Provide time for child and parents to ask questions; answer questions honestly and in terms they can understand *to promote learning.*
- Explain in simplified terms how the child's condition is associated with pain or the rationale for procedures needed that may contribute to pain *to promote understanding and foster trust.*
- Teach in short sessions *to prevent overloading the child and parents with information.*
- Provide reinforcement and rewards *to help facilitate the teaching/learning process.*
- Use multiple modes of learning, such as written information, verbal instruction, demonstrations, and media when possible, *to facilitate learning and retention of information.*
- Instruct parents and child as appropriate in nonpharmacologic methods for pain relief; encourage practice and participation by parents in methods chosen *to foster independence and use of method when necessary.*
- Teach child as appropriate and parents about pharmacologic methods for pain relief; review specific information about drug to be used, including action, duration, administration, possible adverse effects, and care necessary when drug is used, *to promote learning*; have child and parents report back information or demonstrate administration *to evaluate effectiveness of teaching.*
- Provide parents with written information about pain relief methods for use at home if indicated *to allow for reference at a later date.*

Nursing Care Plan 35.1 (continued)

NURSING DIAGNOSIS: Disturbed sleep patterns related to inability to manage pain effectively as evidenced by frequent waking by child during night, signs and symptoms of pain including irritability and restlessness, statements about being tired, pain rating scale

Outcome Identification and Evaluation

Child will exhibit increased ability to sleep during night as evidenced by increasing periods of calm and restfulness (initially starting at 2 hours and gradually increasing to 7 to 8 hours), decreased pain level on pain rating scale, and statements of decreased fatigue.

Intervention: Promoting Sleep and Rest

- Assist child in using nonpharmacologic methods of pain relief, such as imagery, distraction, muscle relaxation, *to promote relaxation.*
- Administer pharmacologic pain relief as ordered *to minimize pain interfering with sleep*; anticipate a change in drug therapy if pain relief is inadequate.
- Cluster nursing care activities *to minimize energy expenditure and disruptions in child's ability to rest.*
- Help child with a nighttime routine similar to one he or she uses at home *to promote feelings of security.*
- Offer child back rub, warm bath, or warm liquids, reading a story, or listening to music *to facilitate relaxation*; provide stroking, hugging, cuddling, rocking, and light touch *to promote a sense of security and calm.*
- Dim the lights and close the curtain or door to the room *to provide a quiet, restful environment.*
- Ensure round-the-clock pain relief for the child through the night *to minimize the risk of pain.*

NURSING DIAGNOSIS: Risk for injury related to possible adverse effects of analgesics

Outcome Identification and Evaluation

Child will remain free of any injury related to signs and symptoms of adverse effects of analgesic therapy as evidenced by respiratory rate appropriate for age, no complaints of GI upset, dizziness, or sedation or episodes of constipation, nausea, vomiting, or pruritus.

Intervention: Promoting Safety

- Ensure that the child's call light is within reach *to allow for notification of health care personnel should problems arise.*
- Administer analgesic exactly as prescribed *to reduce the risk of error and development of adverse effects.*
- Assess child's respiratory status closely for changes *to allow for early detection of respiratory depression.*
- If an opioid analgesic is being given, have naloxone readily available *to reverse the action of the narcotic if respiratory depression occurs.*
- Monitor appetite and assess bowel sounds for changes; note any abdominal distention or decreased bowel sounds, *which would suggest decreased peristalsis.*
- Ensure adequate fluid and fiber intake *to reduce risk of constipation.*
- Offer small frequent meals and give medication with food *to minimize risk of GI upset.*
- Assess for nausea and vomiting; if necessary withhold food and fluids *to rest the GI tract* and administer antiemetics until nausea and vomiting resolve.
- Instruct the child to remain in bed after receiving analgesic, raise crib or side rails as appropriate, and instruct the child and parents to have someone accompany the child to the bathroom if allowed *to reduce the risk of falls from sedation.*
- Assess for complaints of itching and observe for rash or reddened areas; if pruritus occurs, urge the child not to scratch and expect to administer antihistamine as ordered *to reduce pruritus.*
- Provide the child with distraction to assist in helping *to reduce effects of pruritus.*

The type of distraction used depends on the age of the child. For example, a younger child may enjoy blowing pinwheels and blowing bubbles. He or she also will enjoy listening to favorite stories or books. Older children may enjoy computer games, listening to favorite music, or visiting with friends.

Imagery

Imagery involves the use of the imagination to create a mental image. This mental image usually is a positive, pleasurable image, but it need not be real. The child is encouraged to include details and sensations that are associated with the image, such as specific descriptions of the image, colors,

FIGURE 35.9 A child using distraction for pain management.

sounds, feelings, and smells. In some instances, the child may write down or record the image on a tape or compact disc. When pain occurs, the child is encouraged to create the mental image or read or listen to the description.

Biofeedback

Biofeedback involves having the child gain an awareness of his or her body functions and learn ways to modify them voluntarily. The child usually is taught specific skills about how to modify body functions using an apparatus that measures pain-related changes in muscle tone or physiologic data, such as blood pressure or pulse rate. This teaching usually is performed by a specialized health care provider and occurs over several sessions, in advance of the pain experience. With practice, the child learns to control the changes without the apparatus. This technique can be used by older children, such as adolescents, who can concentrate for longer periods of time.

Thought Stopping

Thought stopping involves substituting a pleasurable or positive thought for the painful experience. Examples of positive thoughts might be, "It's only for a short time" or "It's important so I get better." The negative component of the pain is not ignored or suppressed; rather, it is transformed into something positive. Thought stopping also can involve the use of short, positive phrases. For example, the child may repeat "quick stick, feel better, go home soon" when he or she anticipates pain or experiences pain.

Thought stopping is a useful method for reducing anxiety before and during events associated with pain. Children can be taught to use this technique anytime they experience anxiety related to a painful experience. Doing so helps to promote the child's sense of control over the situation.

Positive Self-Talk

Positive self-talk is similar to thought stopping in that it involves the use of positive statements. With positive self-

EVIDENCE-BASED PRACTICE 35.1

What Are the Effects of Distraction on Pain, Fear, and Distress During Venous Port Access and Venipuncture in Children With Cancer?

Children with cancer undergo multiple procedures, and many describe these procedures as the most distressing part of their disease. Distraction can decrease procedural pain, distress, and fear by redirecting the child from threatening to nonthreatening stimuli, resulting in a therapeutic benefit.

● Study

This study used an intervention-comparison group design in a large university-affiliated pediatric medical center. A convenience sample of 50 children with cancer, from 5 to 18 years old, was randomly assigned to either a comparison or an intervention group. Two oncology nurses performed all port access or venipunctures per institutional guidelines. Both groups received standard care with the intervention group also using a self-selected distracter from a pool of five choices, which were chosen based on recommendations in the literature (*I Spy: Super Challenger* book, bubbles, music, VR glasses that allow the child to watch a video in 3-D and listen to music in stereo sound, and Nintendo Gameboy).

▲ Findings

The pain and fear scores were lower in the intervention group, although the difference was not statistically significant. Fear and distress scores were significantly improved from during to after the procedure in the intervention versus the comparison group. Forty-six percent of those in the intervention group stated the current poke was "better" or "much better" than their last one, compared to 39% in the comparison group. Fifty-nine percent of parents in the intervention group, compared to 16% in the comparison group, felt this venous access or venipuncture was better than the last one. Ninety-one percent of those patients in the intervention group stated that the distracter helped and they would use it again. All of the parents (100%) reported the distracter was effective and they would encourage their child to use it again.

■ Nursing Implications

Nurses need to encourage distraction strategies as they have been shown to positively enhance procedure outcomes. The nurse needs to facilitate and encourage parent participation in the use of distraction strategies.

Windich-Biermeier, A., et al. (2007). Effects of distraction on pain, fear, and distress during venous port access and venipuncture in children and adolescents with cancer. *Journal of Pediatric Oncology Nursing, 24*(1), 8–19.

talk the child is taught to say positive statements when he or she is experiencing pain. For example, the child may be taught to say, "I will feel better and be able to go home and play with my friends."

Biophysical Interventions

Biophysical interventions focus on interfering with the transmission of pain impulses reaching the brain. The interventions involve some type of cutaneous stimulation near the site of the pain. This stimulation decreases the ability of the A-delta and C fibers to transmit pain impulses. Examples of biophysical interventions include application of heat and cold, massage and pressure, and transcutaneous electrical nerve stimulation (TENS).

A particular intervention for infants is nonnutritive sucking, which reduces pain behaviors in neonates undergoing painful procedures (Morash & Fowler, 2004). Infants derive satisfaction from sucking. In addition, they show reduced pain behaviors after ingestion of sucrose or other sweet-tasting solutions such as glucose, since these substances are mediated through the opioid pathways (Morash & Fowler, 2004). Nonnutritive sucking is recommended as a technique for providing atraumatic care, but this method must be used with caution in infants with unstable blood glucose levels.

Heat and Cold Applications

Heat and cold applications alter physiologic mechanisms associated with pain. Cold results in vasoconstriction and alters capillary permeability, leading to a decrease in edema at the site of the injury. Due to vasoconstriction, blood flow is reduced and the release of pain-producing substances such as histamine and serotonin also is decreased. Moreover, transmission of painful stimuli via peripheral nerve fibers is decreased.

Heat results in vasodilation and increases blood flow to the area. It also leads to a decrease in nociceptive stimulation and removal of chemical substances that can stimulate nociceptive fibers. The increase in blood flow alters capillary permeability, leading to a reduction in swelling and pressure on nociceptive nerve fibers. Heat may also trigger the release of endogenous opioids, which mediate the pain response.

Massage and Pressure

Massage and pressure, like other biophysical interventions, are believed to inhibit stimulation of the A-delta and C fibers. These methods are helpful in relaxing muscles and reducing tension. In addition, these techniques can aid in distracting the child. Massage can be as simple as rubbing a body part or pressing on an area such as an injection site for about 10 seconds, or it can be more involved, requiring the use of another person to perform the massage. Lotion or ointment can be used during the massage and may provide a comforting effect. Contralateral pressure or massage (i.e., of the opposite area) may be used, especially if the area of pain cannot be accessed or if the affected area is too painful to touch.

A more formal method of pressure application is acupressure. In acupressure the fingertip, thumb, or a blunt instrument is used to apply gentle, firm pressure to specifically designated sites to control pain. The pressure may be applied in one motion followed by releasing, in a circular motion for several minutes and then releasing, or with a vibrating motion using the fingertips. The motion of applying and then releasing pressure is thought to facilitate the release of endogenous endorphins and enkephalins. The techniques of pressure and massage can be taught to children and parents. The techniques are easy to learn and use.

The Nurse's Role in Nonpharmacologic Pain Intervention

The nurse plays a major role in teaching the child and family about nonpharmacologic pain interventions, helping them choose the most appropriate and most effective methods, and ensuring that the child and parents use

TEACHING GUIDELINES 35.1

Teaching to Manage Pain Without Drugs

- Review the methods available and choose the method(s) that your child and you find best for your situation.
- Learn to identify the ways in which your child shows pain or demonstrates he or she is anxious about the possibility of pain—for example, does he or she get restless, make a face, or get flushed in the face?
- Begin using the technique chosen before your child experiences pain or when your child first indicates he or she is anxious about or beginning to experience pain.
- Practice the technique with your child and encourage the child to use the technique when he or she feels anxious about pain or anticipates that a procedure or experience will be painful.
- Perform the technique with your child; for example, take the deep breath in and out or blow bubbles with him or her; listen to the music or play the computer game with your child.
- Avoid using terms such as "hurt" or "pain" that suggest or cause your child to expect pain.
- Use descriptive terms like pushing, pulling, pinching, or heat.
- Avoid overly descriptive or judgmental statements such as, "this will really hurt a lot" or "this will be terrible."
- Stay with your child as much as possible; speak softly and gently stroke or cuddle your child.
- Offer praise, positive reinforcement, hugs, and support for using the technique even when it was not effective.

the method before pain occurs as well as before the pain increases. Teaching Guidelines 35.1 lists some helpful instructions for the parents and child about nonpharmacologic pain management.

The nurse also assists the child and parents when using the technique, ensuring that they are using the technique correctly and offering suggestions for modifications or adaptations as necessary.

Parents are important components of the pain management program. Give them the option to stay with the child, or let them know that someone else will support the child if they opt not to stay. Offer simple, concrete ways to assist and help the child to manage pain. Many of the nonpharmacologic techniques can be done by parents, and children may respond better if their parents demonstrate the technique and encourage them to use it. Invite parents to participate in decisions as well as act as a coach to their child during procedures. Prepare the parents and explain the most appropriate pain management approaches and strategies. Discuss the type and amount of pain expected as well as the potential complications associated with pain management approaches. Ask how the parent predicts the child will react to a painful situation. Finally, offer techniques and strategies to the parents as they act as the coach during these situations.

▶ Take NOTE!

Although parents want to help their children and some are able to act as coaches, the response of the child to pain and stress and to their parents' distraction interventions is highly variable. Some children appear to be soothed by their parents' distraction actions; others appear to become distressed. Be alert to factors that may influence the child's response, including age, sex, diagnosis, ethnicity, previous experience, temperament, anxiety, and coping style. Also be aware of parental factors, including ethnicity, sex, previous experience, belief in the helpfulness of the intervention, parenting style, and parental anxiety (McCarthy & Kleiber, 2006).

Pharmacologic Management

Pharmacologic interventions involve the administration of drugs for pain relief. Administration may occur using a wide variety of methods. The selection of the method is determined by the drug being administered, the child's status, the type, intensity, and location of the pain, and any factors that may be influencing the child's pain. Research overwhelmingly supports the appropriate use of analgesics to reduce pain perception in children (Broome & Huth, 2003).

Medications Used for Pain Management

Analgesics (medications for pain relief) typically fall into one of two categories: nonopioid analgesics and opioid analgesics. Anesthetics also may be used. Drugs such as sedatives and hypnotics also may be used as adjuvant medications to help minimize anxiety or provide or assist with pain relief when typical analgesics are ineffective.

Nonopioid Analgesics

Nonopioid analgesics include acetaminophen and nonsteroidal anti-inflammatory drugs (NSAIDs) such as ibuprofen, ketorolac, naproxen, indomethacin, diclofenac, and piroxicam (Drug Guide 35.1). These agents may be used to treat mild to moderate pain, often for conditions such as arthritis; joint, bone, and muscle pain; headache; dental pain; and menstrual pain. Acetaminophen, probably the most widely known nonopioid analgesic, also is commonly used to treat fever in children, as is ibuprofen.

▶ Take NOTE!

Aspirin should not be used in children for analgesic and antipyretic purposes because of the high risk of Reye's syndrome.

According to the World Health Organization's pain ladder, acetaminophen and NSAIDs are first-line agents for the treatment of pain (WHO, 2006). Although this ladder was developed for the relief of cancer pain, it can be applied to any patient experiencing pain.

Nonopioid agents are typically administered orally or rectally. In some cases, such as with postoperative pain, they may be administered intravenously as a continuous infusion or as bolus doses (Maunuksela & Olkkola, 2003). Administration via intramuscular injection is not recommended because the injection can cause significant pain and the onset of pain relief is not increased.

Adverse effects commonly associated with these agents include gastrointestinal irritation, blood clotting problems, and renal dysfunction. However, research has demonstrated that children experience only mild gastrointestinal upset and negligible effects on a healthy, well-functioning renal system. Blood clotting problems arise primarily when these agents are given perioperatively before primary hemostasis has occurred (Maunuksela & Olkkola, 2003). Nonopioids are relatively safe, have few incompatibilities with other medications, and do not depress the central nervous system. Unfortunately, they exhibit a ceiling effect for analgesia: after a certain level, they do not provide increasing pain relief even when administered at increased doses. As a result, they may be combined with opioids for more effective pain relief.

DRUG GUIDE 35.1 COMMON DRUGS FOR PAIN MANAGEMENT

Drug	Action/Indication	Nursing Implications
Acetaminophen (Tylenol)	Possible inhibition of cyclooxygenase in the central nervous system. Direct action on hypothalamic heat-regulating center. Mild to moderate pain; arthritis, musculoskeletal pain, headache	• Administer orally or rectally. Do not exceed five doses of drug in 24 hours. • Caution parents to read labels of other over-the-counter (OTC) drugs carefully; some may contain acetaminophen and if given in conjunction may lead to overdose.
Ibuprofen (Motrin, Advil)	Inhibition of prostaglandin synthesis Mild to moderate pain, fever	• Administer orally. • Give with food or after meals if GI upset occurs. • Assess for easy bruising, bleeding gums, or frank or occult blood in urine or stool. • Monitor for nausea, vomiting, GI upset, diarrhea or constipation, dizziness or drowsiness. • Caution parents to read labels of OTC medications closely; some may contain ibuprofen or other NSAIDs and if given in conjunction may lead to overdose.
Other NSAIDs: ketorolac (Toradol), diclofenac (Voltaren), indomethacin (Indocin), naproxen (Naprosyn, Aleve)	Inhibition of prostaglandin synthesis Mild to moderate pain	• Administer oral form with food or after meals if GI upset occurs. • Monitor for headache, dizziness, nausea, vomiting, constipation, or diarrhea. • Assess for signs and symptoms of bleeding, such as bruising, epistaxis, gingival bleeding, or frank or occult blood in urine or stool. • Ketorolac: May also be given IV or IM. In children 2–16 years, recommended as single dose only. • Naproxen: Also available in combination products (caution parents to read OTC labels carefully). • Indomethacin: When administering IV, report oliguria or anuria. • Diclofenac: May also be given rectally.
Opioid agents: morphine, codeine, fentanyl (Sublimaze, Duragesic), hydromorphone (Dilaudid), oxycodone (OxyContin)	Opioid agonist acting primarily at mu-receptor sites (morphine, codeine, fentanyl, hydromorphone, oxycodone) Moderate to severe acute and chronic pain. Morphine: intractable pain, preoperative sedation. Codeine: also suppresses cough reflex. Fentanyl: pain associated with short procedures such as bone marrow aspiration, fracture reductions, suturing.	• Assess respiratory status frequently, noting any decrease in ventilatory rate or changes in breathing patterns; have naloxone readily available in case of respiratory depression (particularly morphine, fentanyl, hydromorphone). • Monitor for sedation dizziness, lethargy, confusion. • Educate parents and child that the drug may make the child sleepy, drowsy, or lightheaded. • Institute safety measures to prevent injury to the child. • Assess bowel sounds for decreased peristalsis; observe for abdominal distention. • Ensure adequate fiber intake and administer stool softeners as prescribed to minimize risk for constipation. • Monitor urine output for changes and report. • Morphine: May cause itching, particularly facial. • Codeine: May cause nausea, vomiting, abdominal pain. IV administration results in apnea and severe hypotension. Most commonly administered orally in combination with acetaminophen. • Fentanyl: Observe for chest wall rigidity, which can occur with rapid IV infusion. • Oxycodone is the opioid component of Tylox and Percocet.

(continued)

DRUG GUIDE 35.1 COMMON DRUGS FOR PAIN MANAGEMENT (continued)

Drug	Action and Indication	Nursing Implications
Mixed opioid agonist–antagonist: pentazocine (Talwin), butorphanol (Stadol), nalbuphine (Nubain)	Pentazocine: antagonist at mu-receptor sites, agonist at kappa-receptor sites. Butorphanol: high affinity for kappa-receptor sites, minimal affinity for sigma-receptor sites. Nalbuphine: partial agonist at kappa-receptor sites, antagonist at mu-receptor sites. Moderate to severe pain. Relief of migraine headache (butorphanol). Preoperative analgesia (nalbuphine).	• Monitor the child for sedation. Educate child and parents that the drug may make the child sleepy, drowsy, or lightheaded. • Institute safety measures to prevent injury to the child. • Pentazocine, butorphanol: Monitor for diaphoresis, dizziness. Assess for tachycardia and hypertension. • Butorphanol is given intranasally for migraine headaches.

Opioid Analgesics

Opioid analgesics are typically used for moderate to severe pain. They are classified as either agonists (when they act as the neurotransmitter at the receptor site) or antagonists (when they block the action at the receptor site). Opioid agents that act as agonists include morphine, codeine, fentanyl, meperidine, hydromorphone, oxycodone, and hydrocodone. Opioids that act as mixed agonists–antagonists include pentazocine, butorphanol, and nalbuphine (see Drug Guide 35.1). Opioids can be administered orally, rectally, intramuscularly, or intravenously. In addition, some agents such as fentanyl can be administered transdermally or transmucosally. Morphine is considered the "gold standard" for all opioid agonists; it is the drug to which all other opioids are compared and is usually the drug of choice for severe pain.

Opioid agonists, such as morphine, are associated with numerous adverse effects, resulting primarily from their depressant action on the central nervous system.

▶ *Take* NOTE!

When administering parenteral or epidural opioids, always have naloxone (Narcan) readily available to reverse the opioid's effects should respiratory depression occur.

Opioids stimulate the chemoreceptor trigger zone (CTZ), leading to nausea and vomiting. Moreover, **drug tolerance** (increased dosage required for the same pain relief previously achieved with a lower dose) and **physical dependence** (need for continued administration of the drug to prevent withdrawal symptoms) are commonly noted when opioids are given repeatedly (Yaster et al., 2003). Drug Guide 35.1 gives additional information related to the opioid analgesics.

▶ *Take* NOTE!

Drug tolerance occurs when increasing doses are required to manage the pain. Physical dependence can occur after as few as 5 days of continuous use of the drug; symptoms of withdrawal begin if it is suddenly stopped. To decrease the risk of withdrawal, the dose can be decreased 10% to 20% per day.

Mixed agonist–antagonists are associated with less respiratory depression than agonists. Unfortunately, like NSAIDs, this group also has a ceiling effect, leading to inadequate effectiveness even with increased dosages. When this occurs, increasing the dosage of the mixed agonist–antagonist or combining it with an agonist provides no additional pain relief.

▶ *Take* NOTE!

Meperidine, an opioid agonist, is not *recommended as a first-choice agent for pain relief in children. Meperidine's metabolite, normeperidine, is associated with the development of restlessness, irritability, twitching, agitation, tremors, and most importantly seizures. Normeperidine is a central nervous stimulant and its effects cannot be reversed by an opioid antagonist such as naloxone (American Medical Association, 2006; McCaffrey & Pasero, 1999).*

Adjuvant Drugs

Adjuvant drugs are drugs that are used to promote more effective pain relief, either alone or in combination with non-opioids or opioids. Their primary indication is for diagnoses other than pain. These agents are not classified

as analgesics but may provide a coanalgesic effect or may treat side effects. Benzodiazepines, such as diazepam and midazolam, help to relieve anxiety. Midazolam also produces amnesia. Anticonvulsants, such as carbamazepine, and tricyclic antidepressants, such as amitriptyline and nortriptyline, are used to treat neuropathic pain.

Local Anesthetics

Local anesthetics are commonly used to provide analgesia for procedures. They are effective in providing successful pain relief with only minimal risk of systemic adverse effects. However, local anesthetics such as lidocaine historically were not used in children because they need to be injected; the belief was that children feared needles and use of a local anesthetic subjected the child to two needlesticks instead of one. Advances in technology have led to the development of improved methods of delivery such as topical ointments and iontophoresis for administration of local anesthetics, thereby promoting atraumatic care. (For more detailed discussion, see the next section on drug administration methods and later in the chapter on the nurse's role in managing procedure-related pain.)

Drug Administration Methods

With any medication administered for pain management, the timing of administration is vital. Timing depends on the type of pain. For continuous pain, the current recommendation is to administer analgesia around the clock at scheduled intervals to achieve the necessary effect. Scheduled dosing has been associated with decreased pain intensity ratings for children (Paice et al., 2005). As-needed or PRN dosing is not recommended. This method can lead to inadequate pain relief because of the delay before the drug reaches its peak effectiveness, and as a result the child continues to experience pain, possibly necessitating a higher dose of analgesic to achieve relief; this then places the child at risk for overmedication and toxic effects.

For pain that can be predicted or considered temporary, such as with a procedure, analgesia is administered so that the peak action of the drug matches the time of the painful event.

There are various methods for administering pain medications to children. The preferred methods are the oral, rectal, intravenous, topical, or local nerve block routes. Epidural administration and conscious sedation also can be used.

Oral Method

The oral method is often preferred because it is simple, easy, and convenient. The medication may be in the form of a pill, capsule, tablet, syrup, or elixir. Oral administration provides relatively steady blood levels of the drug when administered as a scheduled dose. Effectiveness typically occurs 1 to 2 hours after administration. Higher doses of the medication may be needed to achieve the same effect when switching the child from a parenteral form to an oral form (Hockenberry et al., 2005).

Rectal Method

The rectal method may be used when the child cannot take the medication orally, such as when he or she has difficulty swallowing or is experiencing nausea and vomiting. It is a viable alternative for drug administration. Some analgesics are available in suppository form; for others that are not, the drug can be compounded into a suppository form. The absorption rate varies with rectal administration, and children may find insertion of a suppository uncomfortable and embarrassing.

Intravenous Method

Intravenous analgesia administration is the method of choice in emergency situations and when pain is severe and quick relief is needed. With intravenous administration, the drug usually takes effect within 5 minutes. Intravenous administration can be accomplished with bolus injections or continuous infusions. Continuous infusions may be preferred over bolus doses because steady blood levels are more easily maintained, thereby enhancing the drug's effect in relieving pain. Typically, opioids such as morphine, hydromorphone, and fentanyl are used due to their short half-life and decreased risk for toxicity.

Patient-Controlled Analgesia

In **patient-controlled analgesia (PCA)**, a computerized pump is programmed to deliver an infusion of analgesics via a catheter inserted intravenously, epidurally, or subcutaneously. The analgesic may be given as a continuous infusion, as a continuous infusion supplemented by patient-delivered bolus doses, or as patient-delivered bolus doses only. Typically the child presses a button to administer a bolus dose. The pump has a lockout function that is preset with the dose and time interval: if the child presses the button before the preset time, he or she will not receive an overdose of medication. By delivering small, frequent doses of opioids, the child can experience pain relief without the effects of oversedation. The child also experiences a sense of control over the pain experience.

PCA has been used successfully in children as young as 5 or 6 years old (D'Arcy, 2007). However, it is essential to assess each child individually and consider his or her developmental level and psychosocial factors in determining appropriate PCA use. The child must have the necessary intellect, manual dexterity, and strength to operate the device. Both the Institute for Safe Medical Practices (ISMP) and the Joint Commission on the Accreditation of Health Care Organizations (JCAHO) have identified infants and young children as not being good candidates for PCA usage (D'Arcy, 2007).

Serious adverse events, such as oversedation, respiratory depression, and even death, can occur when family members, caregivers, or clinicians who are not authorized

administer PCA doses "by proxy." The ISMP recommends developing specific criteria in any situation where authorized agent–activated PCA is being used. Proper education and instruction is crucial in any situation where someone other than the patient may be administering PCA doses. To ensure safety with PCA use, each institution must have policies and procedures in place, appropriate education of health care staff, quality-control measures, and quality machines.

PCA has been used to control postoperative pain and the pain associated with trauma, cancer, and sickle cell crisis. It can be used in acute care settings or in the home. Most commonly, morphine, hydromorphone, and fentanyl are the drugs used with PCA. The dosage is based on the child's response. Initial bolus doses commonly range from 0.015 to 0.02 mg/kg. Dosages for infusions depend on the child's age, the opioid used, and the type of pain. A commonly used range for morphine infusion to treat postoperative pain ranges from 0.01 to 0.04 mg/kg/hour. Higher dosage ranges have been used to treat the pain associated with sickle cell crisis and cancer.

Local Anesthetic Application

A local anesthetic may sometimes be used to alleviate the pain associated with procedures such as venipuncture, injections, wound repair, lumbar puncture, or accessing of implanted ports. Local anesthesia is a type of regional analgesia that blocks or numbs specific nerves in a region of the body. Medications called local anesthetics include topical forms, such as creams, agents delivered by iontophoresis, and vapocoolants and skin refrigerants, and injectable forms.

Topical Forms

The first choice for the most effective, painless local anesthesia is EMLA (eutectic mixture of local anesthetics [lidocaine and prilocaine]). It achieves anesthesia to a depth of 2 to 4 mm, so it reduces pain of phlebotomy, venous cannulation, and intramuscular injections for up to 24 hours after the injection. However, it requires a 60-minute application time to intact skin using an occlusive dressing for superficial procedures and up to 2 to 3 hours for deeper, more invasive procedures (Box 35.1). Sometimes EMLA is not used due to the expense and the time needed to allow the drug to act.

▶ *Take* NOTE!

EMLA cream should not be used in those patients with the rare condition of congenital or idiopathic methemoglobinemia and in infants under the age of 12 months who are receiving treatment with methemoglobin-inducing agents, such as sulfonamides.

BOX 35.1 Applying EMLA

Follow these guidelines when applying EMLA:

- Explain the purpose of the medication to the child and parents, reinforcing that it will help the pain go away.
- Check the scheduled time for the procedure; plan to apply the cream 60 minutes before a superficial procedure such as a heelstick or venipuncture or 2 to 3 hours before a deeper procedure such as a lumbar puncture or bone marrow aspiration.
- Place a thick layer of the cream on the skin at the intended site of the procedure, making sure that the area where the cream is being applied is free of any breaks. Do not rub the cream in once it is applied to the skin.
- Use approximately one third to one half of a 5-g tube for an application.
- Cover the site with a transparent dressing such as Tegaderm or Op-site and secure it so that the dressing is occlusive. Alternatively, use plastic film wrap and tape the edges to secure the dressing.
- Instruct the child not to touch the dressing once it is secured. If necessary, cover the occlusive dressing with a protection device or a loosely applied gauze or elastic bandage.
- After the allotted time, remove the occlusive dressing and wipe the cream from the skin. Inspect the skin for a change in color (blanching or redness), which indicates that the medication has penetrated the skin adequately.
- Verify that sensation is absent by lightly tapping or scratching the area. Use this technique also to demonstrate to the child that the anesthetic is effective. If sensation is present, reapply the cream.
- Prepare the child for the procedure. Assess the child's pain after the procedure to evaluate for pain and to differentiate pain from fear and anxiety.

EMLA is available in two forms: a cream and a topical disc. If the disc form is used, an occlusive dressing is not needed. EMLA is approved for use in infants 37 weeks' gestation or older. Maximum dosage and maximum area of application are based on the child's weight. Parents can be taught how to apply the EMLA cream or disc at home in preparation for a procedure (Fig. 35.10).

▶ *Take* NOTE!

EMLA is contraindicated in children who have congenital or idiopathic methemoglobinemia. It must be used cautiously in those under age 12 months who are receiving methemoglobin-inducing agents, such as sulfonamides, phenytoin, phenobarbital, and acetaminophen. Use of these agents in combination with EMLA increases the child's risk for methemoglobinemia, a condition that could lead to cyanosis and hypoxemia.

FIGURE 35.10 A parent applies EMLA cream to the child at home in preparation for a procedure.

TAC (tetracaine, epinephrine, cocaine) and LET (lidocaine, epinephrine, tetracaine) are other examples of topical anesthetics. These are commonly used for lacerations that require suturing. The agent is applied directly to the wound with a cotton ball or swab for 20 to 30 minutes until the area is numb. These methods are not used in patients with known sensitivity to any of these medications.

Researchers have studied LMX4, an over-the-counter topical anesthetic that provides anesthesia to the applied area in 15 to 30 minutes instead of the 60 minutes required by EMLA. The studies showed that an occlusive dressing was not needed when this topical anesthetic was used.

A study published recently in the *Canadian Medical Association Journal* found that a new topical anesthetic containing liposomal lidocaine 4% cream was highly effective in reducing the pain associated with intravenous cannulation. The researchers cited a short onset of action (30 minutes) and minimal vascular effects as benefits. They found that the liposomal encapsulation protects the anesthetic from being metabolized too quickly. Results of this study showed higher intravenous cannulation success rates, less pain, shorter total procedure time, and minor dermal changes among the children (Taddio et al., 2005).

Another choice for local anesthesia is iontophoresis. Iontophoretic lidocaine (Numby Stuff) provides anesthesia to a depth of 8 to 10 mm in approximately 10 minutes and is used over intact skin. A mild electrical current from a small battery-powered generator and two iontophoretic drug-delivery electrodes push drug molecules (lidocaine HCl 2% with epinephrine 1:100,000) into the skin. This type of local anesthesia is not recommended for use in children who have a history of allergy or sensitivity to these drugs; with children who have electrically sensitive equipment such as a pacemaker; or if damaged skin or scar tissue is present.

Vapocoolant spray, another type of local analgesia, can be sprayed onto the skin or administered using a cotton ball soaked in liquid. The depth of anesthesia is not known, but it appears to provide immediate pain control. It is inexpensive and requires no waiting time. The effect lasts for approximately 1 to 2 minutes.

Injectable Forms

Injectable forms of lidocaine or procaine can be administered subcutaneously or intradermally around the procedural area approximately 5 to 10 minutes before the procedure. Common problems with this form of anesthetic include the pain associated with the subcutaneous injection and some burning associated with lidocaine administration, as well as blanching of the skin.

▶ *Take* NOTE!

The burning that lidocaine causes on injection may be diminished by buffering lidocaine with sodium bicarbonate, using 10 parts lidocaine and 1 part sodium bicarbonate (1 mL of 1% to 2% lidocaine and 0.1 mL of 8.4% sodium bicarbonate). Then inject 0.1 mL or less of the solution intradermally at the site of venipuncture. Anesthetic action is almost immediate. The solution is stable for only approximately 1 week if not refrigerated.

Epidural Analgesia

For epidural analgesia, a catheter is inserted in the epidural space at L1-2, L3-4, or L4-5. The drug, usually fentanyl or morphine, diffuses into the cerebrospinal fluid and crosses the dura mater to the spinal cord. Then it binds with the opioid receptors located at the dorsal horn. The drugs can be administered as bolus injections (a one-time bolus or on an intermittent schedule), a continuous infusion, or PCA. Usually an opioid, such as morphine, fentanyl, or hydromorphone, is given in conjunction with a long-acting local anesthetic such as bupivacaine.

Epidural analgesia is typically used postoperatively, providing analgesia to the lower body for approximately 12 to 14 hours. The small amount of medication used with this type of analgesia causes less sedation, thereby allowing the child to participate more actively in postoperative care activities. This type of analgesia also is effective for

children undergoing upper or lower abdominal surgeries because it controls localized intense pain, somatic pain, and visceral pain.

When epidural analgesia is being administered, additional narcotic analgesics are not given in order to prevent complications such as respiratory depression, pruritus, nausea, vomiting, and urinary retention.

▶ *Take* NOTE!

Respiratory depression, although rare when epidural analgesia is used, is always a possibility. When it does occur, it usually occurs gradually over a period of several hours after the medication is initiated. This allows adequate time for early detection and prompt intervention.

Constant assessment is essential because insertion of an epidural catheter and epidural analgesia can lead to infection at the site of the insertion, epidural hematoma, arachnoiditis, neuritis, or spinal headache (rare) due to a cerebrospinal fluid leak and respiratory depression. Frequent assessment, typically every 1 to 2 hours, of heart rate, respiratory rate, blood pressure, depth of sedation, and pain level is imperative. Assessing for adverse reactions such as nausea and vomiting and pruritus, as well as checking the catheter site and ensuring the occlusive dressing is intact, are all important nursing interventions. The dermatome, which is the area of the body associated with supply by a particular nerve, that innervates the diaphragm can become suppressed during continuous epidural analgesia, resulting in respiratory depression. Therefore the nurse must assess the patient's sensory level frequently. This can be done by using cool water on alcohol pad and bilaterally touching the patient's body every 2 to 3 cm. The level where the patient states he or she feels the temperature change is the level of anesthesia. (Refer to Figure 35.11 for dermatome levels.)

Conscious Sedation

Conscious sedation is a medically controlled state of depressed consciousness that allows protective reflexes to be maintained so the child has the ability to maintain a patent airway and respond to physical or verbal stimulation. This procedure requires adherence to specific protocols as outlined by the Federal Drug Administration Department and Joint Commission on Accreditation of Healthcare Organizations. The depressed state is obtained by using various agents such as morphine, fentanyl, midazolam, or diazepam and other adjuvants such as pentobarbital. Midazolam and fentanyl often are the drugs of choice for conscious sedation because they act quickly, last only a short time, and are available in oral and intravenous formulations (Box 35.2).

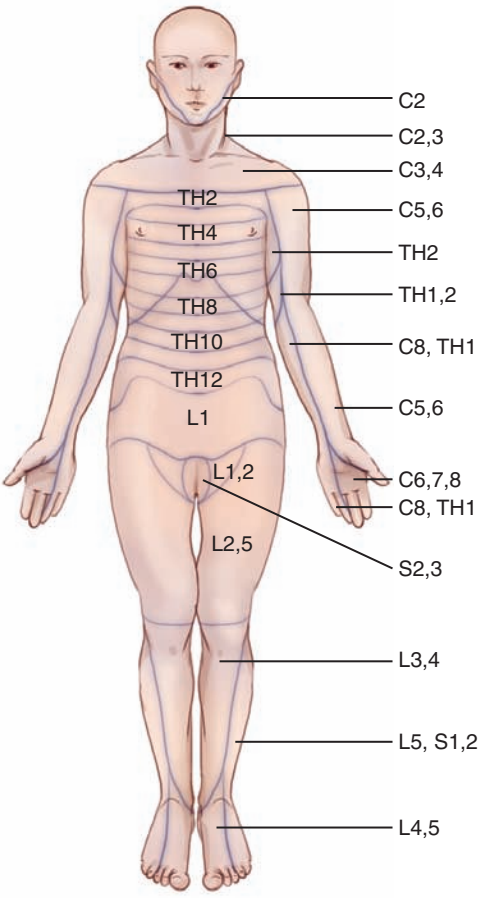

Diagram of Dermatomes

FIGURE 35.11 The level of anesthesia should not go higher than T4, the nipple line, in children.

▶ *Take* NOTE!

The combination of meperidine (Demerol), promethazine (Phenergan), and chlorpromazine (Thorazine), commonly called DPT, is no longer recommended because it has been shown to cause excessive depression of the central nervous system. In addition, chlorpromazine increases the risk of meperidine toxicity, compounding the risk of severe respiratory depression. Promethazine causes extrapyramidal reactions. The combination also must be administered intramuscularly, which causes the child to experience more pain.

Conscious sedation is used for procedures that are painful and stressful. Therefore, the route of administering the medications for sedation should follow the guide-

BOX 35.2 Oral Forms of Midazolam and Fentanyl

Two of the most commonly used agents for conscious sedation are midazolam and fentanyl. Each of these is available in an oral form, which promotes atraumatic care.

Oral midazolam syrup
- Clear purplish-red cherry-flavored syrup
- Syrup containing 2 mg/mL
- Recommended dosage: 0.25 to 0.5 mg/kg to a maximum dose of 20 mg
- Action usually within 10 to 20 minutes
- Major adverse effects: respiratory depression and arrest

Fentanyl Oralet
- Oral transmucosal formulation
- Candy-type lozenge on a plastic holder
- Available in 200, 300, and 400 mg
- Recommended dose: 5 to 15 mcg/kg
- Not recommended for use in children weighing less than 15 kg
- Onset of action in about 15 minutes of sucking lozenge; duration of action approximately 1 hour

lines of atraumatic care. Oral, topical, or an existing intravenous route should be used. For example, conscious sedation is suggested instead of restraints, especially for toddlers and preschool children who are undergoing frightening or invasive procedures and who are manifesting extreme anxiety and behavioral upset. Other indications include situations involving:

- Evidence that the child is experiencing a heightened stress reaction—attempting to flee, crying inconsolably, or flailing
- Verbalization by the child that he or she is frightened and does not want to be touched
- Inability to remain immobilized, such as during laceration repair or computed tomography
- Any procedure that is painful and fear-provoking

Personnel administering conscious sedation must be specially trained, and emergency equipment and medications must be readily available.

The Nurse's Role in Pharmacologic Pain Intervention

The nurse plays a major role in providing pharmacologic pain relief. As with any medication, the nurse is responsible for adhering to the five rights of medication administration: right drug, right dose, right route, right time, and right patient. In addition, the nurse also adheres to three additional rights: the right of the child and parents to be educated; the right of the child to refuse the medication; and the right documentation. The nurse also must have a solid knowledge base about the medications used for pain relief. This knowledge includes information about the drug's pharmacokinetics (absorption, distribution, metabolism, and excretion) and pharmacodynamics (mechanism of action, including adverse effects).

Assessment is crucial when pharmacologic pain interventions are used. An initial assessment of pain provides a baseline from which options for relief can be chosen. Factors that can affect the choice of analgesic, such as the child's age, pain intensity, physiologic status, or previous experiences with pain, also need to be considered. The nurse acts as an advocate for the child and the family to ensure that the most appropriate pharmacologic agent is chosen for the situation.

Assessment is ongoing once the agent is administered. The nurse must monitor physiologic parameters such as level of consciousness, vital signs, oxygen saturation levels, and urinary output for changes that might indicate an adverse reaction to the agent. More intensive monitoring is needed when agents are administered intravenously or epidurally or by conscious sedation. For example, if the child is receiving conscious sedation, interventions include:

- Ensuring that emergency equipment is readily available
- Maintaining a patent airway
- Monitoring the child's level of consciousness and responsiveness
- Assessing the child's vital signs (especially pulse rate, heart rate, blood pressure, and respiratory rate)
- Monitoring oxygen saturation levels

Typically, a specially trained health care provider is specifically designated to perform these activities during the administration of the sedation. Afterwards, the nurse is responsible for ongoing monitoring of the child's status.

Monitor the child closely for evidence of adverse effects. Table 35.8 describes the interventions useful for responding to these adverse effects. Be alert for signs and symptoms of respiratory depression secondary to opioid administration. Have an opioid antagonist such as naloxone (Narcan) and the benzodiazepine antagonist flumazenil (Romazicon) readily available should the child experience respiratory depression.

In addition to assessing physiologic parameters, the nurse must assess the child's and parents' emotional status before and after the agent is administered. For example, increased anxiety and fear may necessitate a change in method of administration, such as topical application instead of an intradermal injection of a local anesthetic. Nonpharmacologic methods may be employed to help lessen anxiety, thereby promoting more effective relief from the drug.

Nurses also are responsible for ensuring that the child and parents are adequately prepared for the use of the pharmacologic agent. The nurse educates the child and

TABLE 35.8 INTERVENTIONS FOR COMMON OPIOID-INDUCED ADVERSE EFFECTS

Adverse Effect	Nursing Interventions
Constipation	Encourage fluid intake unless contraindicated. Ensure intake of high-fiber foods, including fruits, if allowed. Encourage activity, including ambulation if possible. Obtain order for stool softener. Administer laxative as ordered.
Pruritus	Apply cool compresses and lotions. Administer antihistamine as ordered.
Nausea and vomiting	Inform child and parents that these symptoms usually subside in 1 to 2 days. Encourage small frequent meals with bland foods. Administer antiemetic if ordered.

parents about the drug, why it is being used, its intended effects, and possible adverse effects, tailoring the teaching to the child's cognitive level. Provide opportunities for the child and parents to ask questions, offering support and guidance throughout the experience. Provide a demonstration or use visual aids so that the child and parents know exactly what to expect. Encourage the use of play to help the child express fears and anxieties related to the administration.

Management of Procedure-Related Pain

One of the most common causes of pain in children is procedure-related pain. The procedure may be minor, such as an intramuscular injection, heelstick, or venipuncture, or it may be more involved, such as lumbar puncture, bone marrow aspiration, or wound care. Regardless, pain is real for children and painful procedures are often extremely distressing to them. Variables that affect pain include the intensity or length of the procedure and the skill of the health care provider performing the procedure.

The Nurse's Role in Managing Procedure-Related Pain

Through the use of behavioral and pharmacologic approaches, nurses can significantly reduce the pain and distress of procedures. The guiding principle is the provision of atraumatic care to the child, which includes the following:

- Using topical EMLA, iontophoretic lidocaine, vapocoolant spray, or buffered lidocaine at the intended site of a skin or vessel puncture
- Incorporating the use of nonpharmacologic strategies for pain relief in conjunction with pharmacologic methods
- Preparing the child and parents ahead of time about the procedure and then keeping all equipment out of site until it is ready to be used
- Using therapeutic hugging (see Chapter 32) to secure the child
- Using the smallest-gauge needle possible or an automated lancet device to puncture the skin
- Using an intermittent infusion device or peripherally inserted central catheter (PICC) if multiple or repeated blood samples are necessary; coordinating care so that several tests can be performed from one sample if possible
- Opting for venipuncture in newborns instead of heelsticks if the amount of blood needed would require much squeezing
- Using kangaroo care (skin-to-skin contact) for newborns before and after heelstick
- Providing nonnutritive sucking with sucrose solution for newborns several minutes before the procedure (Lefrak, Burch, Caravantes, et al., 2006).

▶ *Take* NOTE!

Individualize interventions based on the painfulness of the procedure and the child's developmental age and personality. Use behavioral-cognitive approaches and pharmacologic interventions. For example, encouraging the school-age child to assist during painful procedures in age-appropriate ways may actually help ease some of the pain related to a heightened state of anxiety, or at least assist the child in coping with the situation. Always use appropriate pharmacologic treatment for the first procedure to provide a painless experience for the child.

Nursing care for the child with procedure-related pain includes the child as well as the parents. Be sure to prepare them for the procedure using an appropriate developmental approach. Promote environmental comfort, too. Ensure

that the child's privacy is maintained and that the lighting is adequate for the procedure but not so bright as to cause the child discomfort.

Painful procedures performed in the child's room can lead to an association of pain or fear with the room or bed. Many hospitals have a special treatment room where procedures can be performed. These rooms are usually equipped with many activities, toys, and decorations to help distract the child. The use of a treatment room may not be feasible or desirable in all situations or for all procedures. The ultimate goal is to do what is best for the child; therefore, the nurse needs to consider the needs of the child, the demands of the procedures, and the conditions that would facilitate the best outcome.

Unless contraindicated, encourage the parents to be present before, during, and after the procedure to provide comforting support to the child. Also encourage the child and parents to use nonpharmacologic methods to help maximize pain relief and reduce anxiety. For example, nonpharmacologic methods that are helpful for the toddler and preschooler may include positioning the child on the lap and hugging the child, distracting the child with toys or interactive books, and blowing bubbles.

Play therapy can be useful when preparing children for painful procedures. Encourage children to make decisions about their care related to pain management if their condition or procedure allows. It is also helpful to anticipate and recognize painful situations and provide pain medication before the actual procedure to ensure comfort. Many nonpharmacologic strategies can be enhanced and better implemented with the help of the child life specialist or play therapist, who have specialized training in these techniques.

Recall Aiden from the beginning of the chapter. What are some interventions that may be helpful prior to, during, and after his dressing change?

Management of Chronic Pain

Typically, pain in children is acute pain, but chronic pain is a significant problem in the pediatric population, affecting approximately 15% to 20% of children (American Pain Society, 2006). Historically, chronic pain was defined by the duration of the pain, such as longer than 3 to 6 months. However, research has identified elements associated with chronic pain as occurring much earlier in time. Currently, chronic pain is identified as the complex interplay of biologic, psychological, and environmental factors. According to the American Pain Society, children with chronic pain and their families experience significant emotional and social consequences from the pain and disability; also, the experience of chronic pain in childhood may predispose the individual to chronic pain in adulthood.

The Nurse's Role in Managing Chronic Pain

The nurse's role in managing chronic pain in children is similar to that for the child experiencing acute pain or procedure-related pain. Assessment of the child's pain is key and should include a history of the present problem. Questions should focus on the onset of the pain, its intensity, duration, and location, and any factors that alleviate or exacerbate it. In addition, the nurse needs to question the child and parents about the impact of the pain on the child's daily life, such as sleep, play, eating, school, and interactions with peers, other family members, and friends. Impact on the family's life also is addressed.

Another key area of assessment is determining how the pain affects the child's and family's level of stress. Areas to address include the child's and parents' feelings of hopelessness, anxiety, and depression. Also question the child and parents about what they think has caused the pain and how they have coped with it. In addition, ascertain what methods the child and parents have used to alleviate the pain and the success of these methods. Inquire about any home remedies or alternative therapies that may have been used.

Review past physical examination findings for clues to the underlying problem. Observe the child's overall appearance, gait, and posture. Assess the child's cognitive level and emotional response, especially related to the experience of pain. Expect to complete a neurologic examination and observe for muscle spasms, trigger points, and increased sensitivity to light touch. Abnormal body postures assumed by the child due to chronic pain may result in the development of secondary pain in the muscles and fascia. When children tense their muscles due to fear of examination, somatic pain may occur.

Various nonpharmacologic and pharmacologic strategies are used to manage chronic pain. Often multiple strategies are combined to address pain relief as well as the pain's impact on other areas, such as sleep or school functioning. When pharmacologic agents are used, the oral form is the method of choice. As with any pain management strategy, education of the child and family is paramount. A referral to a pediatric pain specialist may be needed if the child's pain is not controlled effectively.

Key Concepts

- Pain is a highly individualized subjective experience affecting persons of any age. It is a universal experience and is considered the fifth vital sign.
- Pain management is a critical element in a child's plan of care because children may lack the verbal capacity to describe their pain experience, caregivers and health care providers often have misconceptions about pain, assessment of the complex nature of the pain experience is difficult, and available resources and research related to pain relief strategies in children are limited.

- The sensation of pain involves a sequence of physiologic events: transduction, transmission, perception, and modulation
- Pain can be classified by duration as acute or chronic, by etiology as nociceptive or neuropathic, or by source or location as somatic or visceral.
- Factors influencing a child's perception of pain include age and gender, cognitive level, temperament, previous pain experiences, and family and cultural background, all of which cannot be changed. Situational factors involve behavioral, cognitive, and emotional aspects and can be changed.
- Infants, including preterm infants, experience pain. Behavioral and physiologic indicators are used to assess pain. Toddlers commonly react with intense emotional upset and physical resistance or aggression. Preschoolers may feel that pain is a punishment for misbehaving or having bad thoughts. School-age children can communicate the type, location, and severity of pain but may deny having pain to appear brave or avoid further pain. Adolescents, with their focus on body image and fear of loss of control, often ask numerous questions and may attempt to remain stoic to avoid being viewed as childish.
- Assessment of pain in children includes both subjective and objective data. Nurses need to tailor the assessment to the child's developmental level and ask appropriate questions geared to the child's cognitive level. Parental questioning during the health history also is important.
- Self-report pain rating scales are valuable assessment tools that allow the child's level of pain to be quantified. Examples include the FACES pain rating scale, the Oucher pain rating scale, the poker chip tool, the word-graphic rating scale, visual analog and numeric scales, and the Adolescent Pediatric Pain Tool.
- Different pain rating scales are appropriate for different developmental levels. However, children may regress when in pain, so a simpler tool may be needed to make sure that the child understands what is being asked. Consistency in using the same tool is essential so that appropriate comparisons can be made and effective interventions can be planned and implemented.
- Physical examination of the child for pain primarily involves the skills of observation and inspection. These skills are used to assess for physiologic and behavioral changes that indicate pain. Auscultation also may be used to assess for changes in vital signs, specifically heart rate and blood pressure. Physiologic and behavioral pain assessment tools, such as the Neonatal Infant Pain Scale, Riley Infant Pain Scale, Pain Observation Scale for Young Children, the CRIES Scale for Neonatal Postoperative Pain Assessment, and the FLACC Behavioral Scale for Postoperative Pain in Young Children, measure specific parameters and changes that would indicate that the child is in pain.
- Nonpharmacologic pain management strategies aim to assist children in coping with pain and to give them a sense of mastery or control over the situation. These strategies may be categorized as behavioral-cognitive, in which the child focuses on a specific area or aspect rather than the pain (e.g., relaxation, distraction, imagery, biofeedback, thought stopping, and positive self-talk), or biophysical, in which the focus is on interfering with the transmission of pain impulses reaching the brain (e.g., heat and cold applications, massage and pressure).
- The nurse plays a major role in teaching the child and family about available nonpharmacologic pain interventions, helping them choose the most appropriate and most effective methods, and ensuring that the child and parents use the method before the pain occurs as well as before it increases.
- Pharmacologic interventions involve the administration of drugs for pain relief, most commonly nonopioids and opioid analgesics. The selection of the method is determined by the drug being administered, the child's status, the type, intensity, and location of the pain, and any factors that may be influencing the child's pain. The preferred methods for administering analgesics include the oral, rectal, intravenous, or local nerve block routes, epidural administration, and conscious sedation.
- Nonopioid analgesics used to treat mild to moderate pain include acetaminophen and nonsteroidal anti-inflammatory drugs (NSAIDs) such as ibuprofen, ketorolac, naproxen, and less commonly indomethacin, diclofenac, and piroxicam.
- Morphine is considered the "gold standard" for all opioid agonists; it is the drug to which all other opioids are compared and is usually the drug of choice for severe pain.
- Local anesthetics are commonly used to provide analgesia for procedures. They are effective in providing successful pain relief with only minimal risk of systemic adverse effects. The first choice for the most effective, painless local anesthesia is EMLA (eutectic mixture of local anesthetics [lidocaine and prilocaine]). It achieves anesthesia to a depth of 2 to 4 mm, so it reduces pain of phlebotomy, venous cannulation, and intramuscular injections up to 24 hours after injection.
- Epidural analgesia involves the insertion of a catheter into the epidural space through which drugs can be administered as bolus injections (a one-time bolus or on an intermittent schedule), as a continuous infusion, or as PCA. Usually an opioid, such as morphine, fentanyl, or hydromorphone, is given in conjunction with a long-acting local anesthetic, such as bupivacaine.
- Conscious sedation is a medically controlled state of depressed consciousness that allows protective reflexes to be maintained so the child has the ability to maintain a patent airway and respond to physical or verbal stimulation.

- When providing pharmacologic pain relief, the nurse must adhere to the five rights of medication administration and have a solid knowledge base about the medications used for pain relief and the drug's pharmacokinetics (absorption, distribution, metabolism, and excretion) and pharmacodynamics (mechanism of action, including adverse effects). Initial and ongoing assessment is crucial.
- The principles of atraumatic care guide nursing interventions for providing pain relief, especially for procedure-related pain.
- Chronic pain in children can significantly affect the child's daily life and activities as well as the family's life.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. The nurse is preparing to assess the pain of a 3-year-old child who had surgery the day before. Which pain rating scale would be most appropriate for the nurse to use?

   a. FACES Pain Rating Scale
   b. Poker chip tool
   c. Word-graphic rating scale
   d. Visual analog scale

2. When developing the plan of care for a child in pain, the nurse identifies appropriate strategies aimed at modifying which factors influencing pain?

   a. Gender
   b. Cognitive level
   c. Previous pain experiences
   d. Anticipatory anxiety

3. An adolescent who is a competitive swimmer comes to the emergency department complaining of localized aching pain in his shoulder. He states, "I've been practicing really hard and long to get myself ready for my meet this weekend." The area is tender to the touch. The nurse determines that the adolescent is most likely experiencing which type of pain?

   a. Cutaneous pain
   b. Deep somatic pain
   c. Visceral pain
   d. Neuropathic pain

4. After teaching a child's parents about the different methods of distraction that can be used for pain management, which statement by the parents indicates a need for additional teaching?

   a. "We'll have her focus on her hand and count each finger slowly."
   b. "We'll read some of her favorite stories to her."
   c. "We'll have her imagine that she's at the beach this summer."
   d. "She likes to play video games, so we'll bring in some from home."

5. A child is scheduled for a bone marrow aspiration at 4 p.m. The nurse would plan to apply EMLA cream to the intended site at which time?

   a. 1:30 p.m.
   b. 3:00 p.m.
   c. 3:30 p.m.
   d. 4:00 p.m.

CRITICAL THINKING EXERCISES

1. The nurse asks a 12-year-old girl if she is having pain. She denies pain, even though she is lying on her left side holding her abdomen with her knees flexed up to it. What might be some underlying factors leading the child to deny her pain? How would the nurse go about assessing this child's pain?

2. The nurse comes into the room of a 6-year-old who is sleeping. His mother states, "He's asleep, so he's not in pain." How should the nurse respond?

3. A child who is receiving ibuprofen is experiencing increased pain. The dosage of ibuprofen is increased but is no longer effective in providing adequate pain relief. What is occurring? What would be most likely to happen next?

STUDY ACTIVITIES

1. Interview nurses who work on a pediatric unit about their experiences with managing pain in children. Ask them how they assess pain in children and the major methods they use to assist the children in managing their pain.

2. Interview families of children with chronic illnesses who deal with pain. Ask the parents how they assess their children's pain level and what methods they have used in assisting their children in managing pain.

3. Compare and contrast the drugs fentanyl and midazolam when used for conscious sedation in terms of onset of action, duration, primary effects, and antidotes.

4. A child is receiving epidural analgesia with morphine. The nurse would be alert for which of the following adverse effects? Select all that apply.

   _____ a. Respiratory depression
   _____ b. Pruritus
   _____ c. Constipation
   _____ d. Vomiting
   _____ e. Amnesia
   _____ f. Hematoma

UNIT ELEVEN

Nursing Care of the Child With a Health Disorder

This page intentionally left blank.

CHAPTER 36

Nursing Care of the Child With an Infectious or Communicable Disorder

Samuel Goldberg, 3 months old, is brought to the clinic by his mother. He presents with a history of fever and nasal congestion. His mother tells you, "He's been very irritable and crying more than usual."

KEY TERMS

antigen
antibody
chain of infection
communicability
endogenous pyrogens
exanthem
fomite
pathogen
phagocytosis

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Discuss anatomic and physiologic differences in children versus adults in relation to the infectious process.
2. Identify nursing interventions related to common laboratory and diagnostic tests used in the diagnosis and management of infectious conditions.
3. Identify appropriate nursing assessments and interventions related to medications and treatments for childhood infectious and communicable disorders.
4. Distinguish various infectious illnesses occurring in childhood.
5. Devise an individualized nursing care plan for the child with an infectious or communicable disorder.
6. Develop client/family teaching plans for the child with an infectious or communicable disorder.

Wow

Complete and lasting freedom from infectious disease remains a dream, but one worth fighting a hard battle for.

Infectious and communicable diseases are the leading cause of death worldwide, and their incidence is increasing in the United States (National Center for Infectious Diseases, 2003). They can lead to serious illness in children and significantly affect the lives of these children and their families. They include bacterial infections (e.g., sepsis), viral infections (e.g., viral exanthems and rabies), and parasitic infections (e.g., roundworm and pediculosis capitis [head lice]). Sexually transmitted infections such as chlamydia and gonorrhea are discussed in Chapter 5.

There has been a dramatic decrease in the incidence and severity of infections and communicable diseases since the advent of vaccines, antibiotics, antiviral drugs, and antitoxins. Some diseases have been effectively controlled, but the vast majority will not be eliminated. New diseases emerge and old diseases are reappearing, sometimes in a drug-resistant form. The Centers for Disease Control & Prevention (CDC) tracks certain infectious diseases. This list of nationally reportable diseases is revised periodically to add new pathogens or remove diseases as their incidence declines. Reporting by the states to the CDC is voluntary, so slight variations exist from state to state. Box 36.1 lists nationally reportable diseases.

Nurses, particularly those working in schools, child-care centers, and outpatient settings, are often the first to see the signs of infectious or communicable diseases in children. These signs are often vague at first, consisting of a sore throat or rash. Therefore, nurses must have accurate assessment skills and be familiar with the signs and symptoms of these common childhood diseases so that they can provide prompt recognition, treatment, and guidance and support to families. Identifying the infectious agent is of primary importance to prevent further spread.

Many infectious diseases can be prevented through simple and inexpensive methods such as handwashing, adequate immunization, proper handling and preparation of food, and judicious antibiotic use. Nurses play a key role in educating parents and the community on ways to prevent infectious and communicable diseases.

Infectious Process

Infection occurs when an organism enters the body and multiplies, causing damage to the tissues and cells. The body's response to this damage due to infection or injury is inflammation. The body delivers fluid, blood, and nutrients to the area of infection or injury and attempts to eliminate the pathogens and repair the tissues. The body does this through vascular and cellular reactions. The vascular response is an initial period of vasoconstriction followed by vasodilatation. This vasodilatation allows for the increase of fluids, blood, and nutrients to the area.

The cellular response involves the arrival of white blood cells (WBCs) to the area. WBCs are the body's

BOX 36.1 Nationally Notifiable Diseases

- Chlamydia
- Diphtheria
- Ehrlichiosis
- Gonorrhea
- Lyme disease
- Malaria
- Measles
- Mumps
- Pertussis
- Poliomyelitis, paralytic
- Q fever
- Rabies
- Rocky Mountain spotted fever
- Rubella
- Streptococcal disease, invasive group A
- Syphilis
- Tetanus
- Varicella (morbidity)
- Varicella (deaths only)

For a complete list of nationally notifiable diseases in the United States, go to www.cdc.gov/epo/dphsi/phs/infdis2007r.htm.

HEALTHY PEOPLE 2010

Objective	Significance
Reduce or eliminate indigenous cases of vaccine-preventable diseases. Congenital rubella syndrome (children under age 1 year); diphtheria (persons under age 35 years); *Haemophilus influenzae* type b (children under age 5 years); hepatitis B (persons aged 2 to 18 years); measles (persons of all ages); mumps (persons of all ages); pertussis (children under age 7 years); polio (wild-type virus) (persons of all ages); rubella (persons of all ages); tetanus (persons under age 35); varicella (persons under age 18). Achieve and maintain effective vaccination coverage levels for universally recommended vaccines among young children	• Educate children and their families on the importance of proper immunizations. • Assess immunization status at every healthy encounter. • Provide families with a written record of immunizations given.

TABLE 36.1 FUNCTION OF WHITE BLOOD CELLS BY LEUKOCYTE TYPE

Cell	Cell's Function Is to Combat
Neutrophils (bands and segs)	Pyogenic infection (bacterial)
Eosinophils	Allergic disorders and parasitic infestations
Basophils	Parasitic infections, some allergic disorders
Lymphocytes	Viral infections (measles, rubella, chickenpox, infectious mononucleosis)
Monocytes	Severe infections, by phagocytosis

Source: Fischbach, 2004; adapted from p. 51.

defense against infection or injury. The types of WBCs are neutrophils, lymphocytes, basophils, eosinophils, and monocytes. Elevations in certain portions of the WBC count reflect different processes occurring in the body, such as infection, allergic reaction, or leukemia. Table 36.1 explains the function of each type of WBCs. Each type is generally present in a balanced state; the types are reported as a percentage of the total WBC count or as the number per certain volume of blood.

WBCs use **phagocytosis** to ingest and destroy the **pathogen**. If bacteria escape the action of phagocytosis, they enter the bloodstream and lymph system and the immune system is activated. With activation of the immune system, B lymphocytes (humoral immunity) and T lymphocytes (cell-mediated immunity) are matured and activated. B and T cells recognize and attack infectious pathogens. B cells, which mature in the bone marrow, produce specific antibodies to a specific offending **antigen** (a substance that the body recognizes as foreign). T cells, which mature in the thymus, attack the antigen directly. Once B and T cells have been exposed to an antigen, some cells will remember the antigen: thus, if the particular antigen invades again, the body will act more quickly.

Infection or inflammation caused by bacteria, viruses, or other pathogens stimulates the release of **endogenous pyrogens** (interleukins, tumor necrosis factor, and interferon), resulting in fever. The pyrogens act on the hypothalamus, where they trigger prostaglandin production and increase the body's temperature set point. This triggers the cold response, resulting in shivering, vasoconstriction, and a decrease in peripheral perfusion to help decrease heat loss and allow the body's temperature to rise to the new set point. Fever, defined as a temperature greater than 38°C (100.4°F), then occurs. Box 36.2 gives specific parameters for fever based on the measurement route.

Antipyretics are often used to lower fever and increase client comfort. They decrease the temperature set point by inhibiting the production of prostaglandins, leading to sweating and vasodilation and therefore heat loss and a drop in temperature.

It is important to distinguish between fever and hyperthermia. Hyperthermia occurs when normal thermoregulation fails, resulting in an unregulated rise in core temperature. Hyperthermia may occur if the central nervous system of the child becomes impaired by disease, drugs, and abnormalities of heat production or thermal stressors, such as being left in a hot automobile or exertional heat stroke. In the absence of hyperthermia and in the normally neurologic child, the body does not allow fever to rise to lethal levels. The body actually produces a natural antipyretic, called cryogen. If there is no hyperthermic insult, it is rare to see a child's temperature rise to above 41.4°C (106°F) (Crocetti & Serwint, 2005).

Stages of Infectious Disease

Infectious diseases follow a similar pattern. They progress through certain stages (Table 36.2) in which **communicability** (ability to spread to others) can be predicted. It is important for nurses to understand these stages to help control and manage infectious diseases.

Chain of Infection

The **chain of infection** is the process by which an organism is spread. Behaviors of infants and young children, mainly pertaining to hygiene, increase their risk for infection by promoting the chain of infection. Poor hygiene habits, including lack of handwashing, placing toys and hands in the mouth, drooling, and leaking diapers, all can contribute to the spread of infection and communicable diseases. Table 36.3 reviews the chain of infection and nursing implications related to it.

BOX 36.2 **Definition of Fever by Measurement Route**

- Oral: >37.5°C (99.5°F)
- Rectal: >38°C (100.4°F)
- Axillary: >37.3°C (99.1°F)
- Tympanic: >38°C (100.4°F)

TABLE 36.2 Stages of Infectious Disease

Stage	Explanation
Incubation	Time from entrance of pathogen into the body to appearance of first symptoms; during this time, pathogens grow and multiply
Prodrome	Time from onset of nonspecific symptoms such as fever, malaise, and fatigue to more specific symptoms
Illness	Time during which client demonstrates signs and symptoms specific to an infection type
Convalescence	Time when acute symptoms of illness disappear

Preventing the Spread of Infection

Nurses play a key role in breaking the chain of infection and preventing the spread of diseases. Nurses must not only follow infection control and prevention practices but also educate parents and children on the measures they can take to prevent the spread of infection.

▶ **Take** NOTE!

Frequent handwashing is the most important way to prevent the spread of infection.

Isolation precautions help nurses break the chain of infection and provide strategies to prevent the spread of pathogens among hospitalized clients. Guidelines can be

TABLE 36.3 Chain of Infection

Chain Link	Explanation	Nursing Implications

Infectious agent	Any agent capable of causing infection; examples: bacteria, viruses, rickettsiae, protozoa, and fungus	• Control or eliminate infectious agents through:
		  • Handwashing
		  • Wearing gloves
		  • Cleaning, disinfection, or sterilization of equipment

Reservoir	A place where the pathogen can thrive and reproduce; examples: human body, animals, insects, food, water, inanimate objects (e.g., stethoscopes)	• Control or eliminate reservoirs. • Control sources of body fluids, drainage, or solutions that may harbor pathogens. • Follow institutional guidelines for disposing of infectious wastes. • Provide proper wound care; change dressings or bandages when soiled. • Assist clients to carry out appropriate skin and oral care. • Keep linens clean and dry.
Portal of exit	A way for the pathogen to exit the reservoir; examples: skin and mucous membranes, respiratory tract, urinary tract, gastrointestinal tract, reproductive tract	• Control portals of exit and educate clients and families. • Cover mouth and nose when sneezing or coughing. • Avoid talking, coughing, or sneezing over open wounds or sterile fields. • Use personal protective equipment.
Modes of transmission	Direct transmission: body-to-body contact Indirect transmission: transferred by **fomite** or vector; spread by droplet or airborne transmission	• Wash hands before and after client contact, invasive procedures, or touching open wounds. • Use personal protective equipment when necessary. • Urge clients and family to wash hands frequently, especially before eating or handling food, after eliminating, and after touching infectious material.
Portal of entry	A way for the pathogen to enter the host; examples: skin and mucous membranes, respiratory tract, urinary tract, gastrointestinal tract, reproductive tract	• Use proper sterile technique during invasive procedures. • Provide appropriate wound care. • Dispose of needles and sharps in puncture-resistant containers. • Provide all clients with their own personal care items.
Susceptible host	Any person who cannot resist the pathogen	• Protect susceptible host by promoting normal body defenses against infection. • Maintain integrity of the client's skin and mucous membranes. • Protect normal defenses by regular bathing and oral care, adequate fluid intake and nutrition, proper immunization.

found on the CDC website (www.cdc.gov/ncidod/dhqp/gl_isolation.html). Additional guidelines are available from various infection control societies and regulatory agencies such as the Occupational Safety and Health Administration. Infection control standards have also been developed by the Joint Commission on Accreditation of Healthcare Organizations. This leads to an array of complex guidelines that all health professionals need to be familiar with.

The Hospital Infection Control Practices Advisory Committee (HICPAC) has presented guidelines for hospitalized clients that include two tiers. Tier 1 is standard precautions, which are designed for the care of all clients in the hospital regardless of their diagnosis. Tier 2 is transmission-based precautions, designed for clients who are known or suspected to be infected with epidemiologically important pathogens. These pathogens can be spread by airborne, droplet, or contact transmission. Box 36.3 gives an overview of standard and transmission-based precautions.

When caring for children, these guidelines may need to be modified. For instance, diaper changing is routine in the pediatric setting. Since it does not usually soil hands, it is not mandatory to wear gloves (except if gloves are required due to transmission-based precautions). According to the standard precaution guidelines, single rooms are required for those who are incontinent and cannot control bodily excretions. Since the majority of young children are incontinent, obviously this guideline is inappropriate in the pediatric setting. Pediatric units often have common rooms, such as playrooms and schoolrooms. Children placed on transmission-based isolation are not allowed to leave their rooms and therefore are not allowed to use these common rooms.

Variations in Pediatric Anatomy and Physiology

Normal immune function is an amazing protective response by the body. It involves complex responses including phagocytosis, humoral immunity, cellular immunity, and activation of the complement system. Blood and lymph are responsible for transporting the agents of the immune system. Due to the immature responses of the immune system, infants and young children are more susceptible to infection. The newborn displays a decreased inflammatory response to invading organisms, contributing to an increased risk for infection. Cellular immunity is generally functional at birth, and humoral immunity occurs when the body encounters and then develops immunity to new diseases. Since the infant has had limited exposure to disease and is losing the passive immunity acquired from maternal antibodies, the risk of infection is higher. Young children continue to have an increased risk for infection and communicable disorders because disease protection from immunizations is not complete. (Refer to Chapter 30 for further details.)

Common Medical Treatments

A variety of medications and other medical treatments are used to treat infectious disorders in children. Most of these treatments will require a physician's order when the child is in the hospital. The most common treatments and medications are listed in Common Medical Treatments 36.1 and Drug Guide 36.1. The nurse caring for the child with an infectious disorder should be familiar with what the procedures are, how they work, and common nursing implications related to use of these modalities.

NURSING PROCESS OVERVIEW FOR THE CHILD WITH A COMMUNICABLE DISORDER

Care of the child with an infectious disorder includes assessment, nursing diagnosis, planning, interventions, and evaluation. There are a number of general concepts related to the nursing process that may be applied to the care of children with infectious disorders. From a general understanding of the care involved for a child with an infectious disorder, the nurse can then individualize the care based on the client's specifics.

Remember Samuel, the 3-month-old with fever, congestion, and irritability? What additional health history and physical examination assessment information should you obtain?

Assessment

Assessment of the child with a communicable or infectious disorder includes health history, physical examination, and laboratory and diagnostic testing.

Health History

The health history comprises past medical history, including the mother's pregnancy history, family history, and history of present illness (when the symptoms started and how they have progressed), as well as treatments used at home. The past medical history might be significant for lack of recommended immunizations, prematurity, maternal infection during pregnancy or labor, prolonged difficult delivery, or immunocompromise. Family history might be significant for lack of immunization or recent infectious or communicable disease. When eliciting the history of the present illness, inquire about the following:

- Any known exposure to infectious or communicable disease
- Immunization history
- History of having any common childhood communicable diseases

(text continues on page 1106)

BOX 36.3 Standard Precautions and Isolation Precautions

Standard Precautions (Tier One)

- Apply to all clients
- Apply to all body fluids, secretions, and excretions except sweat; nonintact skin; and mucous membranes
- Designed to reduce the risk of transmission of microorganisms from recognized and unrecognized sources
- Techniques include:
  - Proper hand hygiene
  - Use of gloves (clean and sterile) when touching blood, body fluids, secretions or excretions, and contaminated items
  - Masks, eye protection, and face shields when client care may include splashing or sprays of blood, body fluid secretions or excretions
  - Fluid-resistant nonsterile gowns, to protect skin and clothing, when client care may include splashing or sprays of blood, body fluid secretions or excretions
  - Client care equipment handled in a manner that prevents skin or mucous membrane exposure and contamination of clothing
  - All used linen is considered contaminated and needs to be handled and disposed of appropriately.
  - Precautions used to prevent injury when using, cleaning, or disposing of needles and sharps
  - Mouthpieces, resuscitation bags, and other ventilation devices should be readily available.

Transmission-Based Precautions (Tier Two)

Designed for clients with known or suspected infection with pathogens for which additional precautions are warranted to interrupt transmission

Airborne

- Designed to reduce the risk of infectious agents transmitted by airborne droplet nuclei or dust particles that may contain the infectious agent
- Examples of such illnesses include measles, varicella, tuberculosis.
- Techniques include standard precautions as well as:
  - Private room (if unavailable, consider cohorting clients with the same disease and consult with an infection control professional)
  - Room with negative air pressure ventilation, with air externally exhausted or high-efficiency particulate air filtered if recirculated
  - If infectious pulmonary tuberculosis is suspected or proven, wear a respiratory protective device, such as N95 respirator, while in the client's room.
  - Susceptible health care personnel should not enter the room of clients with measles or varicella zoster infections. Those with proven immunity to these viruses need not wear a mask.

Droplet

- Designed to reduce the risk of infectious agents transmitted by contact of the conjunctivae or the mucous membranes of the nose or mouth of a susceptible person with large-particle droplets containing pathogens generated from a person (generally through coughing, sneezing, talking, or procedures such as suctioning) who has a clinical disease or who is a carrier of the disease
- Examples of such illnesses include diphtheria, pertussis, streptococcal group A, influenza, mumps, rubella, scarlet fever.
- Techniques include standard precautions as well as:
  - Private room (if unavailable, consider cohorting clients with the same disease. If this is not possible, separation of at least 3 feet between other clients and visitors should be maintained.)
  - Wear a mask if within 3 feet of the client.

Contact

- Most important and most common route of transmission of health care–associated infections
- Designed to reduce the risk of infectious agents transmitted by direct or indirect contact. Direct-contact transmission involves skin-to-skin contact and physical transfer of pathogens between a susceptible host and an infected or colonized person. Examples include client care activities that involve physical contact such as turning and bathing. Direct-contact transmission also can occur between two clients, where one serves as the source of infectious pathogen and the other as a susceptible host. Indirect-contact transmission involves contact of a susceptible host with a contaminated intermediate object, usually inanimate, in the client's environment.
- Examples of such illnesses include diphtheria*, pediculosis, scabies, multidrug-resistant bacteria.
- Techniques include standard precautions as well as:
  - Private room (if unavailable, consider cohorting clients with the same disease)
  - Gloves (clean or sterile) should be used at all times.
  - Proper hand hygiene after glove removal
  - Use gowns, unless the client is continent and contact of clothing with client and client environmental surfaces is not anticipated. Remove gowns before leaving the client's room.

Prevention standards are applied in all health care settings and are modified to meet each setting's unique needs. Health care workers must practice within the specific institution's guidelines.

*Certain infections require more than one precaution.

COMMON MEDICAL TREATMENTS 36.1

Treatment	Explanation	Indications	Nursing Implications
Hydration	Promoting proper fluid balance either orally or intravenously	Child who can't replace insensible loss due to fever, child who is vomiting or has diarrhea	• Encourage oral fluids, if possible. • Offer child preferred fluid; try Popsicles or games to promote fluid intake. • If administering IV fluids, ensure proper fluid and rate per order and assess IV site and fluid intake every hour. • Maintain strict record of intake and output.
Fever reduction	Reducing temperature by use of antipyretics or non-pharmacologic interventions	Febrile child who is uncomfortable or who can't keep up with the increased metabolic demands associated with fever	• Administer antipyretics, such as ibuprofen and acetaminophen. • Avoid aspirin use in children and adolescents. • Use non-pharmacologic interventions such as dressing lightly, removing blankets, use of a fan, tepid bath, and cooling blanket. Make sure that non-pharmacologic measures do not induce shivering or discomfort. If they do, they should be stopped immediately.

DRUG GUIDE 36.1 COMMON DRUGS FOR COMMUNICABLE DISORDERS

Medication	Action/Indication	Nursing Implications
Antibiotics	Kill and prevent the growth of bacteria Used for treatment of bacterial infections such as sepsis	• Check for antibiotic allergies. • Give as prescribed for the length of time prescribed.
Antivirals (e.g., acyclovir)	Kill and prevent the growth of viruses Used for treatment of viral infections such as herpes simplex II	• Observe infusion site for signs of tissue damage. • If administering topically, clean and dry area before application and wear gloves. • Give as prescribed for the length of time prescribed.
Antipyretics (acetaminophen, ibuprofen)	Decrease the temperature set point (only in a child with a raised temperature) by inhibiting the production of prostaglandins, leading to heat loss (through vasodilation and sweating) and resulting in a reduction in fever Used to decrease temperature in the febrile child who is uncomfortable or who can't keep up with the increased metabolic demands associated with fever	• Ensure proper dosing, concentration, and dosing interval. • Avoid aspirin use in children and adolescents. • Avoid ibuprofen use in children with a bleeding disorder. • Assess fever and any related symptoms such as tachycardia, shivering, diaphoresis. • Properly educate caregivers on appropriate dosing, concentration, dosing interval, and use of accurate measuring device.
Antipruritics (usually antihistamines)	Given orally or topically to block the histamine reaction Used to relieve discomfort associated with itching	• When applying topically, wear gloves. • Do not apply to open wounds. • Oral antihistamines may cause drowsiness.

- Fever
- Sore throat
- Lethargy
- Malaise
- Poor feeding or appetite
- Vomiting
- Diarrhea
- Cough
- Rash (in the older child ask for a description of how it feels; is it painful, does it itch?)

▶ *Take* NOTE!

Many childhood infections and communicable diseases involve a rash. Rashes can be difficult to identify; therefore, obtaining a thorough description and history from the caregiver is important.

Physical Examination

Physical examination of the child with an infectious disorder includes inspection, observation, and palpation.

Inspection and Observation

The physical examination should begin with inspection and observation. Assess the child's skin, mouth, throat, and hair for lesions or wounds. Note the color, shape, and distribution of any lesions or wounds. Assess whether there is any exudate from the lesions or wounds. Observe for scratching, restlessness, and avoidance of the use of a body part or guarding of a body part. A thorough and accurate description is important to assist in identifying the rash and causative organism. Observe the child's affect, energy level, and interaction with caregivers. Lethargy can indicate serious infection or sepsis. Observe if there is any discharge from the nose, cough, or respiratory difficulty.

Assess hydration status. Inspect the oral mucosa; dry and pale mucous membranes can indicate dehydration. Observe for other signs of dehydration, such as sunken eyes and no tears with crying.

Assessment of vital signs can provide more information about the child's condition. Elevated temperature can indicate infection. Often tachypnea and tachycardia accompany fever. Hypotension may also occur, but it is usually a late sign with sepsis.

▶ *Take* NOTE!

Neonates may not present with fever; some may be hypothermic.

Palpation

Palpate the skin to assess temperature, moisture, texture, and turgor. In a child with an infectious or communicable disease, the skin may be warm and moist due to fever. Turgor may be decreased secondary to dehydration. In infants, palpate the fontanels; if they are sunken, the infant may be dehydrated. Palpate the rash to determine if it is raised or flat. A thorough picture of the presenting rash can help identify the child's illness. Palpate the lymph nodes and note any that are swollen and tender.

Laboratory and Diagnostic Testing

Common Laboratory and Diagnostic Tests 36.1 discusses the tests used most commonly when communicable disorders are suspected. The tests can assist the physician in diagnosing the disorder and/or be used as guidelines in determining ongoing treatment. Laboratory or non-nursing personnel obtain some of the tests, while the nurse might obtain others. In either instance the nurse should be familiar with how the tests are obtained, what they are used for, and normal versus abnormal results. This knowledge will also be necessary when providing client and family education related to the testing.

Obtaining Blood Specimens

Giving a blood specimen may be very frightening to children because of the fear of needles, pain, and blood loss. Provide atraumatic care when performing venipunctures and other needlesticks in children. Whether the laboratory technician or the nurse is drawing the blood, the procedure should be performed in an area other than the child's bed, such as the treatment room; the child's bed should be kept as a "safe" area. Provide teaching about the procedure based on the child's developmental level and readiness to learn. In infants and younger children, additional assistance with positioning and restraint will be needed in perform the procedure safely and to ensure proper collection. Use a topical anesthetic cream or gel, refrigerant spray, or iontophoresis prior to venipuncture. In young infants, administer oral sucrose beginning 1 to 2 minutes prior to the procedure and throughout the course of the venipuncture. Refer to Chapter 35 for additional information about decreasing venipuncture-related pain in infants and children.

The usual sites for obtaining blood specimens via venipuncture are the superficial veins of the dorsal surface of the hand or the antecubital fossa, although other locations may also be used. In specific situations, the jugular or femoral vein may be used; in this case either the physician or advanced practice nurse will perform the venipuncture.

Capillary puncture of the child's fingertip, the great toe, or the infant's heel may also be used to obtain blood specimens. Fingertip puncture is similar to that in the

COMMON LABORATORY AND DIAGNOSTIC TESTS 36.1

Test	Explanation	Indications	Nursing Implications
Complete blood count (CBC)	Evaluate white blood cell count (particularly the percentage of individual white cells)	Detect the presence of inflammation, infection	• Normal values vary according to age and gender. • White blood cell count differential is helpful in differentiating source of infection. • May be affected by myelosuppressive drugs
Erythrocyte sedimentation rate (ESR)	Nonspecific test used in conjunction with other tests to determine presence of infection or inflammation	Detect the presence of inflammation, infection	• Send to laboratory immediately; specimens allowed to stand for longer than 3 hours may produce a falsely low result.
C-reactive protein (CRP)	Nonspecific test that measures a type of protein produced in the liver that is present during episodes of acute inflammation or infection Usually used to diagnose bacterial infections; does not consistently rise with viral infections	To detect the presence of infection, CRP is a more sensitive and rapidly responding indicator than ESR.	• Presence of an intrauterine device may cause positive test results because of tissue inflammation. • Exogenous hormones, such as oral contraceptives, may cause increased levels. • Nonsteroidal anti-inflammatories, salicylates, and steroids may cause decreased levels. • Fasting may be required.
Blood culture and sensitivity	Deliberate growing of microorganism in a solid or liquid medium. Once it has grown, it is tested against various antibiotics to determine which antibiotics will kill it.	Detect the presence of bacteria or yeast, which may have spread from a certain site in the body into the bloodstream Determine which antibiotics the bacteria or yeast is sensitive to	• Follow aseptic technique and hospital protocol to prevent contamination. • Two cultures obtained from two different sites are preferred. • Ideally obtain before administering antibiotics; if client is taking antibiotics, notify laboratory and draw specimen shortly before next dose. • Deliver specimen to laboratory immediately (within 30 minutes).
Stool culture (including stool for ova and parasites [O&P])	To determine if a bacteria or parasite has infected the intestines	Detect pathogens, including parasites or overgrowth of normal flora in the bowel. Indicated for clients with diarrhea, fever, or abdominal pain.	• Stool must be free of urine, water, and toilet paper. • Do not retrieve out of toilet water. • Deliver to laboratory immediately. • Mineral oil, barium, and bismuth interfere with the detection of parasites; specimen collection should be delayed for 7 to 10 days. • Often a minimum of three specimens on 3 separate days are required for adequate examination, since many parasites and worm eggs are shed intermittently.

(continued)

COMMON LABORATORY AND DIAGNOSTIC TESTS 36.1 (continued)

Test	Explanation	Indications	Nursing Implications
Urine culture	Collection of urine to detect the presence of bacteria in the urine	Detect the presence of bacteria in the urine. Indicated for clients with fever of unknown origin, dysuria, frequency or urgency, or if urinalysis suggests infection.	• Should be obtained by midstream clean-catch, catheterization, or suprapubic aspiration. Avoid contamination with stool, vaginal secretions, hands, or clothing. • Placing bags on the perineum is not acceptable due to high chance of contamination. • Obtain before antibiotics are administered. • Deliver to laboratory immediately or refrigerate.
Throat culture	Vigorous swabbing of the tonsillar area and posterior pharynx to detect the presence of invasive organisms	Most reliable method of detecting group A streptococcal pharyngitis Will also detect *Bordatella pertussis, Corynebacterium diphtheriae* May be performed in those with fever of unknown origin	• Ensure specimen is of secretions in the pharyngeal or tonsillar area. • When performing on young children, have adult hold child in lap. • Health care worker needs to stabilize head by placing hand on the child's forehead.

adult, directed to the sides of the fingertip. Great toe puncture is performed in the same way. Capillary heel puncture must be performed in the proper location to avoid striking the medial plantar artery or periosteum (see Nursing Procedure 36.1). Automatic lancet devices can be used to deliver a more precise puncture depth (Folk, 2007). The young infant will benefit from the use of oral sucrose via pacifier before and during the capillary puncture.

Occasionally, blood samples may be obtained from an artery rather than a vein or capillary. Blood gases in particular are usually obtained by arterial puncture. Arterial puncture requires additional training and in many institutions is performed only by the respiratory therapist, physician, or nurse practitioner. Children with indwelling venous access devices may be spared the trauma of puncture for blood specimens. Follow your institution's guidelines for withdrawing blood from peripherally inserted venous catheters or central venous catheters. The initial blood will be discarded to prevent contamination with intravenous fluids or medications such as heparin. The amount discarded depends on the size of the catheter, the weight of the child, and the institution's guidelines. After aspirating the specimen, flush the venous access device with normal saline to prevent clogging. The device may then be reconnected to the intravenous fluid or flushed according to the institution's protocol.

Nursing Diagnoses, Goals, Interventions, and Evaluations

After completing a thorough assessment, the nurse might identify several nursing diagnoses, including:

- Altered Body Temperature: Fever
- Impaired Comfort
- Impaired Skin Integrity
- Risk for Infection
- Fluid Volume Deficit
- Social Isolation
- Knowledge Deficit

After completing an assessment of Samuel, you note the following: rectal temperature of 39°C, poor sucking, and lethargy. Based on these assessment findings, what would your top three nursing diagnoses be for Samuel?

Nursing goals, interventions, and evaluation for the child with a communicable or infectious disorder are based on the nursing diagnoses. Nursing Care Plan Overview 36.1 provides a general guide for planning care for a child with an infectious or communicable disorder. Additional

Nursing Procedure 36.1

CAPILLARY HEEL PUNCTURE

1. Choose the collection site and apply a commercial heel warmer or warm pack for several minutes prior to specimen collection.
2. Assemble equipment:
   - Gloves
   - Automatic lancet
   - Antiseptic wipe
   - Cotton ball or dry gauze
   - Capillary blood collection tube
   - Band-aid
3. Don gloves. Remove the warm pack.
4. Cleanse the site with antiseptic prep pad and allow to dry.
5. Hold the dorsum of the foot with the nondominant hand; with the dominant hand, pierce the heel with the lancet.
6. Wipe away the first drop of blood with the cotton ball or dry gauze.
7. Collect the blood specimen with a capillary specimen collection tube. Avoid squeezing the foot during specimen collection if possible, as it may contribute to hemolysis of the specimen.
8. Hold a dry gauze over the site until bleeding stops, then apply a Band-aid.

information about nursing management will be included later in the chapter as it relates to specific disorders.

Managing Fever

Fever is one of the most common reasons parents seek medical attention. Most infections or communicable diseases are accompanied by fever. Many parents have great concerns about fever: they fear febrile seizures, neurologic complications, and a potential serious underlying disease. Many health care providers share these fears. This leads to the common recommendation to intervene and reduce fever. These fears and misconceptions about fever can lead to mismanagement of fever, such as inappropriate dosing of antipyretics or inappropriate use of nonpharmacologic treatments such as sponging the child with alcohol or cold water.

Health care providers need to educate parents that fever is a protective mechanism the body uses to fight infection. Evidence exists that an elevated body temperature actually enhances various components of the immune response. Fever can slow the growth of bacteria and viruses and increase neutrophil production and T-cell proliferation (Crocetti & Serwint, 2005). Studies have shown that the use of antipyretics may prolong illness. Concern also exists that reducing fever may hide signs of serious bacterial illness.

▶ *Take* NOTE!

Infants less than 3 months of age with a rectal temperature greater than 38°C should be seen by a physician. They are considered at risk for sepsis until proven otherwise due to their immature immune system and inability to localize or handle infection very well.

In infants over 3 months of age, fever less than 39°C usually does not require treatment (Kliegman et al., 2007). Antipyretics provide symptomatic relief but do not change the course of the infection. The major benefits of decreasing fever are increasing comfort in the child and decreasing fluid requirements, which helps to prevent dehydration. Children with certain underlying conditions, such as cardiovascular disease or pulmonary disease, also benefit from treating fever because such treatment decreases demands on the body.

Home Management of Fever

Fever is typically managed at home, so it is important for nurses to give guidance and instruction at well-child visits; this information should be reviewed at subsequent visits. Written and video materials about fever management may be effective in increasing caregivers' knowledge. Parents can refer to the written instructions when needed (see Teaching Guidelines 36.1).

The use of acetaminophen or ibuprofen to reduce fever in children has been shown to be safe and effective when the appropriate dose is administered at the appropriate interval (Crocetti & Serwint, 2005). Box 36.4 gives dosing recommendations.

▶ *Take* NOTE!

Never give aspirin to children to reduce fever, due to the risk of Reye syndrome.

Acetaminophen Use

Acetaminophen is widely used and accepted, but toxic reactions can be seen in children. Causes of acetaminophen toxicity include overdosing or incorrect dosing due to failure to read and understand the label instructions, use of an incorrect measuring device or concentration, and co-administration with an over-the-counter fixed-dose combination medication (the parent may not recognize that it has acetaminophen in it). Another factor that may cause acetaminophen toxic-

(text continues on page 1113)

Nursing Care Plan 36.1

Overview for the Child With an Infectious or Communicable Disorder

NURSING DIAGNOSIS: Altered body temperature: fever related to infectious disease process as evidenced by rectal temperature greater than 38°C or 100.4°F

Outcome Identification and Evaluation

Child will maintain temperature within adaptive levels and be comfortable and remain hydrated.
Temperature will be 38°C or 100.4°F or less.
Child will verbalize or exhibit signs of comfort during febrile episode; child will demonstrate adequate signs of hydration.

Interventions: Managing Fever

- Assess temperature at least every 4 to 6 hours, 30 to 60 minutes after antipyretic is given and with any change in condition; *recognizing the pattern of fever may help identify source.*
- Use same site and device for temperature measurement *to reflect a more accurate trend in temperature, since different sites can result in significant differences in temperature reading.*
- Administer antipyretics per physician order when the child is experiencing discomfort or cannot keep up with the metabolic demands of the fever. *Fever is a protective response of the body to fight infection. Antipyretics provide symptomatic relief but do not change the course of the infection. The major benefits to decreasing fever are increasing comfort in the child and decreasing fluid requirements, helping to prevent dehydration.*
- Notify physician of temperature per institution or specific order guidelines; *increases in temperature may indicate worsening infection and relevant changes in condition.*
- Assess fluid intake and encourage oral intake or administer intravenous fluids per physician order; *increased metabolic rate and diaphoresis related to fever can cause fluid loss and lead to fluid volume deficit.*
- Keep linens and clothing clean and dry; *diaphoresis can leave clothing and linen soaked, increasing discomfort for the child.*
- Use of non-pharmacologic measures such as tepid bath and removal of clothing and blankets is controversial. If used, discontinue if shivering begins.

NURSING DIAGNOSIS: Impaired comfort related to infectious and/or inflammatory process as evidenced by hyperthermia, pruritus, rash or skin lesions, sore throat, or joint pain

Outcome Identification and Evaluation

Pain or discomfort will be reduced to level acceptable to child.
Child will verbalize absence or decrease of pain using a pain scale (FLACC, faces or linear pain scale), will verbalize decrease in uncomfortable sensations such as itching and aches; infants will exhibit decreased crying and ability to rest quietly.

Interventions: Improving Comfort

- Assess pain and response to interventions frequently with use of pain scales or other pain measurement tools; *provides baseline of pain and allows for evaluation of effectiveness of interventions.*
- Administer analgesics and antipruritics as ordered *to relieve pain via interruption of CNS pathways and to decrease discomfort related to itching.*
- Apply cool compresses to areas of pruritus or provide a cool bath *to decrease inflammation and soothe pruritus.*
- Keep child's fingernails short (use mitts, gloves, or socks over hands if necessary) *to prevent injury to the skin, which leads to increased pain.*
- Encourage child to press on rather than scratch the area of pruritus; *pressing on the area that itches can soothe the itching and prevent scratching, which can lead to skin injury.*
- Provide fluids frequently and offer warm fluids such as soup or cold foods such as Popsicles *to ease the discomfort of a sore throat.*
- Provide cool mist humidification *to ease the discomfort of a sore throat.*
- Dress the child in light clothing; *restrictive clothing and diaphoresis can lead to increased pruritus.*
- Use diversional activities and distraction appropriate to developmental level: *distraction from pain can reduce the need for pharmacologic agents, and distraction for pruritus can minimize scratching.*

Nursing Care Plan 36.1 (continued)

NURSING DIAGNOSIS: Impaired skin integrity related to mechanical trauma secondary to infectious disease process as evidenced by rash, pruritus, and scratching

Outcome Identification and Evaluation

Child will maintain or regain skin integrity.
Child will not demonstrate increased skin breakdown. Child or parent will be able to describe or demonstrate measures to protect and heal skin and proper care for any lesions.

Interventions: Promoting Skin Integrity

- Monitor skin for color changes, temperature, redness, swelling, warmth, pain or signs of infection, changes in rash lesions, distribution, or size *to help identify problems early and allow for prevention of infection; can also provide information regarding the course of the illness.*
- Encourage fluid intake and proper nutrition *to promote wound healing.*
- Keep child's fingernails short (use mitts, gloves, or socks over hands if necessary) *to prevent injury to the skin, which leads to increased pain.*
- Encourage child to press on rather than scratch the area of pruritus; *pressing on the area that itches can soothe the itching and prevent scratching, which can lead to skin injury.*
- Use antipruritics and topical ointments or creams as ordered *to minimize scratching to prevent injury to skin; can aid in healing.*

NURSING DIAGNOSIS: Risk for infection related to insufficient knowledge regarding measures to avoid exposure to pathogens, increased environmental exposure to pathogens, transmission to others secondary to contagious organism or presence of infectious organisms

Outcome Identification and Evaluation

Child will exhibit no signs or symptoms of local or systemic infection. Child will not spread infection to others. *Symptoms of infection will decrease over time; others will remain free of infection. Child and family will demonstrate appropriate hygiene measures using proper technique, such as handwashing, to prevent the spread of infection.*

Interventions: Preventing and Controlling Infection

- Monitor vital signs; *elevation in temperature may indicate infection.*
- Monitor skin lesions for signs of local infection: *redness, warmth, drainage, swelling, and pain at lesions can indicate infection.*
- Maintain aseptic technique and practice good handwashing *to prevent introduction of further infectious agents and prevent transmission to others.*
- Administer antibiotics as prescribed *to prevent or treat bacterial infection.*
- Encourage nutritious diet and proper hydration according to child's preferences and ability to feed orally *to assist body's natural defenses against infection.*
- Isolate child as required based on transmission-based precautions *to prevent nosocomial spread of infection.*
- Teach child and family preventive measures such as good handwashing, covering mouth and nose with cough or sneeze, and proper disposal of used tissues *to prevent nosocomial or community spread of infection.*

(continued)

Nursing Care Plan 36.1 (continued)

NURSING DIAGNOSIS: Fluid volume deficit, risk for, related to increased metabolic demands and insensible loss due to fever, vomiting, poor feeding or intake

Outcome Identification and Evaluation

Fluid volume will be maintained and balanced. *Oral mucosa is moist and pink, skin turgor is elastic, urine output is at least 1 to 2 mL/kg/hr.*

Interventions: Promoting Adequate Fluid Balance

- Administer IV fluids if ordered *to maintain adequate hydration in children who are NPO, unable to tolerate oral intake, or unable to keep up with fluid losses.*
- When oral intake is allowed and tolerated, encourage oral fluids *to promote intake and maintain hydration.*
- Assess for signs of adequate hydration such as pink and moist oral mucosa, elastic skin turgor, adequate urine output *to detect fluid imbalance.*
- Monitor intake and output *to identify fluid imbalance.*
- Assess urine specific gravity, urine and serum electrolytes, blood urea nitrogen, creatinine, and osmolality and daily weights *to monitor fluid status.*

NURSING DIAGNOSIS: Social isolation related to required isolation from peers secondary to transmission-based precautions, as evidenced by disruption in usual play secondary to inability to leave hospital room, activity intolerance, and fatigue

Outcome Identification and Evaluation

Child will participate in stimulating activities. *Child is able to verbalize reason for isolation and length of isolation (if developmentally appropriate); child verbalizes interest in activities.*

Interventions: Preventing Social Isolation

- Explain reasons for transmission-based precautions and length of time; *this helps increase understanding and decrease anxiety about isolation. Children sometimes mistake isolation as punishment. Explaining length of time gives child an end-point he or she can work toward.*
- Visit child frequently, at least every hour, and try to spend some uninterrupted time to play and allow child time to verbalize feelings about separation from others; *helps establish a therapeutic relationship and demonstrates caring.*
- Let child see caregiver's face before applying mask if appropriate *to help child identify and relate to those caring for him or her and minimize anxiety about strangers and the unknown.*
- Consult child life specialist *to arrange for stimulating activities child enjoys; can help child to understand reasons for isolation.*
- Contact volunteers to spend time with child, if appropriate: *gives child attention and support, which will help child to cope and decrease stress.*

NURSING DIAGNOSIS: Knowledge deficit related to lack of information regarding medical condition, prognosis, and medical needs as evidenced by verbalization, questions, or actions demonstrating lack of understanding regarding child's condition or care

Outcome Identification and Evaluation

Child and family will verbalize accurate information and understanding about condition, prognosis, and medical needs. *Child and family demonstrate knowledge of condition and prognosis and medical needs, including possible causes, contributing factors, and treatment measures.*

Interventions: Providing Client and Family Teaching

- Assess child's and family's willingness to learn: *child and family must be willing to learn in order for teaching to be effective.*
- Provide family with time to adjust to diagnosis *to facilitate adjustment and ability to learn and participate in child's care.*
- Repeat information *to give family and child time to learn and understand.*
- Teach in short sessions; *many short sessions are more helpful than one long session.*
- Gear teaching to level of understanding of the child and family (depends on age of child, physical condition, memory) *to ensure understanding.*
- Provide reinforcement and rewards *to facilitate the teaching/learning process.*
- Use multiple modes of learning involving many senses (provide written, verbal, demonstration, and videos) when possible; *the child and family are more likely to retain information when it is presented in different ways using many senses.*

EVIDENCE-BASED PRACTICE 36.1
The Effect of Physical Methods Such as Sponging on Decreasing Body Temperature in Children

Health care providers commonly recommend physical methods such as sponging to decrease elevated temperature in children.

● Study
The authors reviewed seven randomized and quasi-randomized studies that evaluated the effects of sponging alone or in combination with antipyretic drugs. Study participants included children from the age of 1 month to 15 years.

▲ Findings
Tepid water sponging alone was found to have limited usefulness but may decrease fever in some children if used along with antipyretic drugs. Iced water or alcohol should never be used for sponge bathing as adverse effects such as excess shivering, goose pimples, increased irritability, and febrile seizures occurred more frequently with these types of sponge baths.

■ Nursing Implications
To alleviate some of the concerns that parents have with fever, nurses should educate parents about why fever occurs. Discourage parents from using alcohol baths or ice water to decrease body temperature in children. Counsel parents to administer appropriate doses of antipyretics when fever causes discomfort in the child or if the child is at risk for febrile seizures. Advise parents that tepid bathing in a warm room may safely be used in conjunction with antipyretics to decrease fever in children.

Meremikwu, M., & Oyo-Ita, A. (2007). Physical methods for treating fever in children. *The Cochrane Library 2007, 4.* Indianapolis: John Wiley & Sons.

ity is the controversial but common practice of alternating acetaminophen and ibuprofen to help reduce fever. There is no evidence supporting this practice (Serwint et al., 2007), and it can result in overdose or improper administration. It can be hard for parents to keep track of the time each medication is due. Parents may confuse which medication is given every 4 hours and which is given every 6 hours. They may exceed the recommended daily doses or may confuse the strength or dosage of the medicines.

TEACHING GUIDELINES 36.1
Fever Management

- Fever is a sign of illness, not a disease; it is the body's weapon to fight infection.
- Diurnal variation may allow temperature changes as much as 1°C (1.8°F) over a 24-hour period, peaking in the evening.
- In some children fever can be associated with a seizure or dehydration, but this will not lead to brain damage or death. Discuss the facts about febrile seizures (see Chapter 37 for further information on febrile seizures).
- Watch for the signs and symptoms of dehydration; it is important to provide oral rehydration by increasing fluid intake.
- Dress the child lightly and avoid warm, binding clothing or blankets.
- The use of sponging with tepid water is controversial; if used, encourage the parent to give an antipyretic prior to sponging. Ensure the sponging does not produce shivering (which causes the body to produce heat and maintain the elevated set point), and reinforce the importance of using tepid water, not cold water or alcohol. Instruct the parent to stop if the child experiences discomfort.
- Call the physician for:
  - Any child less than 3 months of age who has a rectal temperature above 38°C (100.4°F)
  - Any child who is lethargic or listless, regardless of temperature
  - Fever lasting more than 3 to 5 days
  - Fever greater than 40.6°C (105°F)
  - Any child who is immunocompromised by illness, such as cancer or HIV, will need further evaluation and treatment.

BOX 36.4 Dose Recommendations for Acetaminophen and Ibuprofen

Acetaminophen, 10 to 15 mg/kg/dose
- No more than every 4 hours
- No more than 5 doses in a 24-hour period

Ibuprofen, 5 to 10 mg/kg/dose
- Only children >6 months of age
- No more than 4 doses in a 24-hour period

Take NOTE!

The American Academy of Pediatrics has stated that due to the lack of evidence supporting the safety or efficacy of alternating acetaminophen with ibuprofen for fever management, extreme discretion should be used when considering this therapy.

Managing Skin Rashes

Many infectious or communicable diseases are accompanied by skin rashes. These rashes can be very uncomfortable and irritating for the child. Management often occurs at home, so parents need to be educated on ways to relieve the discomfort and protect and maintain skin integrity. Antipruritics, including oral medications or topical creams or ointments, may be prescribed by the physician (see Drug Guide 36.1). Parents need to be instructed on the importance of maintaining skin integrity to prevent infection or scarring. Teach parents to keep their child's fingernails short and hands clean. Explain the importance of discouraging scratching, and discuss distraction techniques they can use with the child. Cool compresses or cool baths can relieve itching. Encourage the child to press on rather than scratch the itchy area; this can relieve discomfort while maintaining skin integrity. Refer to Chapter 45 for more information on managing skin rashes.

Based on your top three nursing diagnoses for Samuel, describe appropriate nursing interventions.

Sepsis

Sepsis is a systemic overresponse to infection resulting from bacteria (most common), fungi, viruses, or parasites. It can lead to septic shock, which results in hypotension, low blood flow, and multisystem organ failure. Septic shock is a medical emergency and clients are usually admitted to an intensive care unit (see Chapter 52). The cause of sepsis may not be known, but common causative organisms in children include *Neisseria meningitidis, Streptococcus pneumoniae,* and *Haemophilus influenzae.* Sepsis can affect any age group but is more common in neonates and young infants. Neonates and young infants have a higher susceptibility due to their immature immune system, inability to localize infections, and lack of IgM immunoglobulin, which is necessary to protect against bacterial infections.

The prognosis for sepsis is variable and depends on the child's age and the cause of the sepsis. The mortality rate may be as high as 40% to 60% for certain types of infections (Kliegman et al., 2007). Neonates are at the highest risk, and 50% of neonatal deaths result from serious bacterial infections in the first month of life (Crawford, 2006). Due to this high mortality rate, when a febrile neonate presents, a full work-up is indicated, and usually admission to the hospital to rule out sepsis is the standard of practice.

Pathophysiology

Sepsis results in the systemic inflammatory response syndrome (SIRS) due to infection. The pathophysiology of sepsis is complex. It results from the effects of circulating bacterial products or toxins, mediated by cytokine release, occurring as a result of sustained bacteremia. The pathogens cause an overproduction of proinflammatory cytokines, previously termed endotoxins, which are responsible for the clinically observable effects of the sepsis. Impaired pulmonary, hepatic, or renal function may result from excessive cytokine release during the septic process.

Therapeutic Management

Therapeutic management of sepsis in infants, especially neonates, is more aggressive than for older children. Neonates and infants with sepsis or even suspected sepsis are treated in the hospital. The infant is admitted for close monitoring along with antibiotic therapy. Intravenous antibiotics are started immediately after the blood, urine, and cerebrospinal fluid cultures have been obtained. The length of therapy and the specific antibiotic used will be determined based on the source of the positive culture and the results of the culture and sensitivity. Common treatment length for positive cultures is 10 to 14 days. If final culture reports are negative and symptoms have subsided, antibiotics may be discontinued (usually after 72 hours of treatment). If the child is not responding to therapy and symptoms worsen, sepsis may be progressing to shock. Management of the child with septic shock is usually done in the intensive care unit.

Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1103. Assessment findings pertinent to sepsis are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Signs of sepsis can vary with each child. Some common signs and symptoms reported during the health history might include:

- Child just does not look or act right
- Crying more than usual, inconsolable
- Fever
- Hypothermia (in neonates and those with severe disease)
- Lethargic and less interactive or playful
- Increased irritability
- Poor feeding or poor suck
- Rash (e.g., petechiae, ecchymosis, diffuse erythema)
- Difficulty breathing
- Nasal congestion
- Diarrhea
- Vomiting
- Decreased urine output
- Hypotonia
- Changes in mental status (confused, anxious, excited)
- Seizures
- Older child may complain of heart racing

Explore the child's current and past medical history for risk factors such as:

- Prematurity
- Lack of immunizations
- Immunocompromise
- Exposure to communicable pathogens

In neonates and young infants, seek pregnancy and labor risk factors such as:

- Premature rupture of membranes or prolonged rupture
- Difficult delivery
- Maternal infection or fever, including sexually transmitted infections
- Resuscitation and other invasive procedures
- Positive maternal group beta-streptococcal vaginosis

Sepsis may occur in the hospitalized child. Assess for risk factors such as:

- Intensive care unit stay
- Presence of central line or other invasive lines or tubes
- Immunosuppression

Physical Examination

Perform a thorough physical examination of the infant or child with proven or suspected sepsis. Specific findings related to inspection and observation are noted below.

Inspection and Observation

Observe the child's general appearance, color, level of arousal, and hydration status. The child with sepsis may appear lethargic and pale and show signs of dehydration. In neonates and infants, observe the quality of their cry and reaction to parental stimulation, noting weak cry, lack of smile or facial expression, or lack of responsiveness. Inspect the skin for petechiae or other skin lesions. Petechiae may indicate a serious bacterial infection (often *N. meningitidis*), and other skin lesion patterns may help identify the cause of the fever. Observe respiratory effort and rate. The infant or child with sepsis may demonstrate tachypnea and increased work of breathing, such as nasal flaring, grunting, and retractions.

Assess vital signs, noting abnormalities. Note elevation in temperature or hypothermia in the young infant. Note tachypnea or tachycardia in the child or apnea or bradycardia in the infant. Document blood pressure. Hypotension, especially when accompanied by signs of poor perfusion, can be a sign of worsening sepsis with progression to shock (refer to Chapter 52).

▶ *Take* NOTE!

Listen to the parents' descriptions of the neonate's or infant's behavior and appearance, as well as changes they have observed. Many times they are the first to notice when their child is not acting right, even before clinical signs of infection are seen.

Laboratory and Diagnostic Tests

Symptoms of sepsis can be vague in infants. Therefore, laboratory tests play a crucial role in confirming or ruling out sepsis. Common laboratory and diagnostic studies ordered for the assessment of sepsis include:

- Complete blood count: WBC levels will be elevated; in severe cases they may be decreased (this is an ominous sign)
- C-reactive protein: elevated
- Blood culture: positive in septicemia, indicating bacteria is present in the blood
- Urine culture: may be positive, indicating presence of bacteria in the urine
- Cerebrospinal fluid analysis: may reveal increased WBCs and protein and low glucose
- Stool culture: may be positive for bacteria or other infectious organisms
- Culture of tubes, catheters, or shunts suspected to be infected: the fluid inside these tubes may be tested for bacteria
- Chest x-ray: may reveal signs of pneumonia such as hyperinflation and patchy areas of atelectasis or infiltration

Nursing Management

Monitor the infant or child closely for changes in condition, especially the development of shock. Administer antibiotics as ordered. Refer to the Nursing Care Plan Overview 36.1

for nursing diagnoses and related interventions. In addition to these interventions, reducing risk for infection and providing education to the child and family should be done.

Preventing Infection

Sepsis is a potentially life-threatening illness, and prevention is important. Handwashing is the most effective intervention against nosocomial infection. Nurses play a key role in minimizing environmental sources by cleaning equipment and disposing of soiled linens and dressings properly and adhering to proper aseptic technique with all invasive procedures. Following your institution's policies and using evidence-based practice guidelines for interventions such as invasive line dressing changes and intravenous tubing changes can reduce the risk of infection. Encourage immunization as recommended. To reduce streptococcus group B infection in neonates, screen pregnant woman; if the results are positive, administer intrapartum antibiotics.

Take NOTE!

There has been a dramatic reduction in invasive Haemophilus influenzae *type B diseases since the widespread use of the Hib vaccine. Meningococcal and pneumococcal vaccines also have decreased the incidence of invasive infection, especially in high-risk children.*

Educating the Child and Family

Early recognition of the signs of sepsis is essential in preventing morbidity and mortality. Educate parents about the importance of fever, especially in neonates and infants less than 3 months old. Instruct parents to contact their health care provider if their infant or neonate has a fever. A health care provider should see any child with a fever accompanied by lethargy, poor responsiveness, or lack of facial expressions. Signs and symptoms of sepsis can be vague and vary from child to child. Parents need to be encouraged to contact their health care provider if they feel their febrile child is "just not acting right."

Bacterial Infections

Bacteria are one-celled organisms that can live, grow, and reproduce. They exist everywhere. Most are completely harmless and some are very useful. Others can lead to disease either because they are in the wrong place in the body or they are designed to invade and cause disease in humans and animals. Children are at a high risk of developing bacterial infections, which can result in life-threatening illness. Fortunately, many bacterial diseases, such as diphtheria, pertussis, and tetanus, can be prevented by immunization (see Chapter 30 for more information on immunizations).

SCARLET FEVER

Scarlet fever is an infection resulting from group A streptococci. The bacteria produce a toxin that causes a rash. Two children may both have a group A streptococcus infection, but both may not get the rash of scarlet fever: only the one who is sensitive to the toxin will develop scarlet fever. It is usually seen in children less than 18 years of age, with the peak incidence between the ages of 4 and 8 years. It is rare in children less than 2 years old. Transmission is airborne and follows contact with respiratory tract secretions. Close contact that occurs in schools and childcare centers facilitates transmission. Foodborne outbreaks have occurred due to human contamination of food. After exposure the incubation period is 2 to 5 days. Communicability is highest during acute infection, and the child is no longer contagious 24 hours after the initiation of appropriate antimicrobial therapy.

There has been a dramatic decrease in the mortality from scarlet fever due to antibiotic use, but complications such as rheumatic fever and glomerulonephritis can still occur.

Nursing Assessment

Symptoms of scarlet fever begin abruptly. The history may reveal a fever greater than 101°F, chills, body aches, loss of appetite, nausea, and vomiting. Inspect the pharynx, which is usually very red and swollen. The tonsils may have yellow or white specks of pus, and cervical lymph nodes may be swollen. Inspect the skin for the most striking symptom of scarlet fever, which is an erythematous rash appearing on the face, trunk, and extremities. The rash is typically absent from the palms and soles of the feet. It looks like a sunburn but feels like sandpaper (Fig. 36.1A). The rash lasts approximately 5 days and is followed by desquamation, typically on the fingers and toes. Early in the illness the tongue develops a thick coat with a strawberry appearance. The tongue will later lose the coating and become bright red (see Fig. 36.1B).

Diagnosis is made by identification of group A streptococcus on throat culture. Several rapid tests for group A streptococcal pharyngitis are available. The accuracy of these tests depends on the quality of the specimen. It is important that the secretions obtained are pharyngeal or tonsillar (see Common Medical Treatments 36.1 for more information on throat cultures).

Nursing Management

Children with scarlet fever are usually cared for at home. Penicillin V is the antibiotic of choice. In those sensitive to penicillin, erythromycin may be used. Educate the family on the importance of taking the antibiotic as directed and finishing all the medicine.

Encourage fluid intake to maintain adequate hydration due to fever. Teach parents ways to provide comfort for the child. A cool mist humidifier can soothe the child's sore

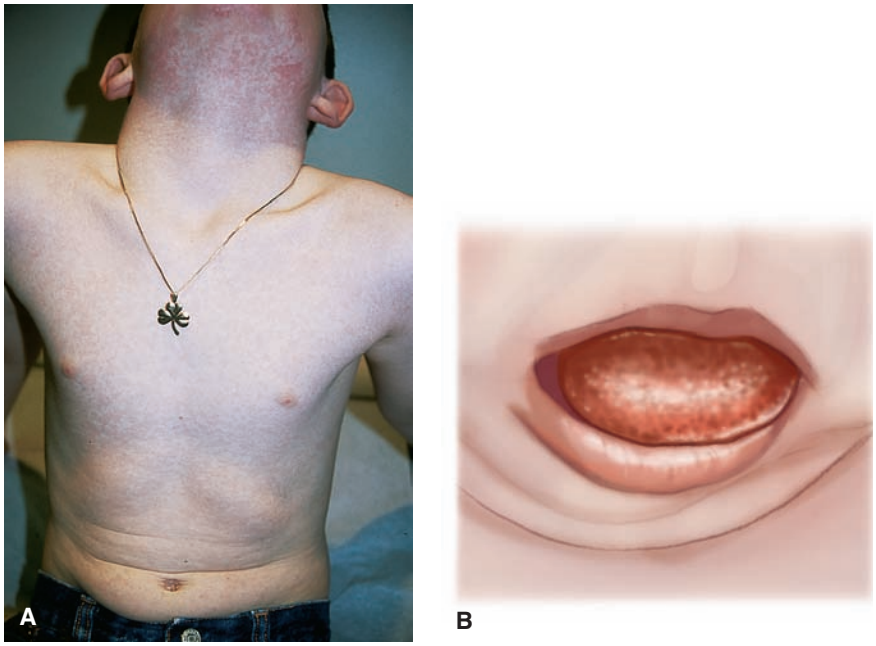

FIGURE 36.1 (**A**) Rash of scarlet fever. (**B**) Strawberry tongue.

throat. Soft foods, warm liquids like soup, or cold foods like Popsicles may also be helpful. If the child is hospitalized, droplet precautions, along with standard precautions, are necessary.

CAT SCRATCH DISEASE

Cat scratch disease is a relatively common and occasionally serious disease caused by the bacteria *Bartonella henselae*. It occurs in both children and adults but is more common in children under 10 years of age. Cats can carry the bacteria in their saliva, and in 90% of cases the child has had a recent interaction with cats and often kittens (Pickering, 2006). No evidence exists to support person-to-person transmission. *B. henselae* is transmitted between cats via the cat flea. The incubation period is 7 to 12 days, with lymphadenopathy appearing in 5 to 50 days. Therapeutic management is supportive and is aimed at management of symptoms. The disease itself is usually self-limited, resolving on its own in 2 to 4 months. If lymphadenopathy persists or if the child is immunocompromised, antibiotics may be needed. Painful, swollen nodes may be treated with needle aspiration to provide symptom relief.

Nursing Assessment

Note history of headaches and fatigue. The history may also include interaction or rough play with cats or kittens, resulting in a scratch. Document the temperature, noting fever. Palpate for enlarged lymph nodes, noting their location. A skin papule may be present or reported. Diagnostic tests are available to detect serum antibodies to antigens of *Bartonella* species.

Nursing Management

Administer antibiotics if ordered. No transmission-based isolation is required; standard precautions are sufficient. Educate the client and family about prevention and control measures. Teach children to avoid rough play with cats and kittens. Teach parents and children to immediately wash any bites or scratches with soap and running water. Explain that cats should never lick open wounds on the child. Control of fleas in cats is important to prevent the spread of *B. henselae*.

DIPHTHERIA

Diphtheria is caused by infection with *Corynebacterium diphtheriae* and may affect the nose, larynx, tonsils, or pharynx. Tonsillar and pharyngeal infections are the most common and will be the focus of this discussion. A pseudomembrane forms over the pharynx, uvula, tonsils, and soft palate (Fig. 36.2). The neck becomes edematous and lymphadenopathy develops. The pseudomembrane causes airway obstruction and suffocation. Diphtheria generally occurs in children less than 15 years old who are unimmunized. Routine infant immunization can prevent the disease. Therapeutic management involves administration of antibiotics and antitoxin, as well as airway management.

Nursing Assessment

Children at risk for diphtheria are those who are unimmunized. Note history of sore throat and fever, usually less than 38.9°C. As the pseudomembrane forms, swallowing becomes difficult and signs of airway obstruction

FIGURE 36.2 In diphtheria a pseudomembrane forms over the pharynx, uvula, tonsils, and soft palate.

become apparent. A specimen of the membrane may be cultured for *C. diphtheriae.*

Nursing Management

Close observation of respiratory status is of utmost importance. Administration of antibiotics and the antitoxin is critical to encourage sloughing of the membrane. The child should remain on strict droplet precautions in addition to standard precautions and should maintain bed rest.

PERTUSSIS

Pertussis is an acute respiratory disorder characterized by paroxysmal cough (whooping cough) and copious secretions. It primarily occurs in children 4 years and younger and is most severe in children less than 6 months of age. The disease is caused by *Bordatella pertussis.* The incubation period is 6 to 21 days, usually 7 to 10 days. Pertussis usually starts with 7 to 10 days of cold symptoms. The paroxysmal coughing spells then begin and can last 1 to 4 weeks. Convalescence occurs over the course of several weeks to months. Immunization has decreased the incidence of pertussis, but the increasing numbers of unimmunized children, particularly immigrants, contribute to the incidence of the disease. Complications include seizures, pneumonia, encephalopathy, and death.

Therapeutic Management

Therapeutic management of pertussis focuses on eradicating the bacterial infection and providing respiratory support. CDC guidelines recommend antimicrobial treatment. For infants older than 1 month of age, macrolide drugs, including erythromycin, clarithromycin, and azithromycin, are the drugs of choice. For younger infants, azithromycin should be used and erythromycin and clarithromycin avoided. An alternative to macrolides in children older than 2 months is trimethoprim–sulfamethoxazole (TMP-SMZ).

Nursing Assessment

The most important risk factor for the development of pertussis is lack of immunization. The history may reveal cold and cough symptoms, progressing to paroxysmal coughing spells. During the paroxysms, the child might cough 10 to 30 times in a row, followed by a whooping sound. This might be accompanied by redness in the face, progressive cyanosis, and protrusion of the tongue. Saliva, mucus, and tears flow from the mouth, nose, and eyes. Between the paroxysmal episodes, the child might rest well and appear relatively unaffected. Auscultate the lungs to assess air exchange. The diagnosis may be confirmed by an immunofluorescent assay positive for *B. pertussis.*

Nursing Management

Nursing care will focus on providing a high-humidity environment and frequent suctioning to mobilize secretions. Observe for signs of airway obstruction. Encourage fluids to keep secretions thin and maintain adequate hydration. Offer reassurance to the child and family; the coughing episodes can be very frightening. Droplet precautions along with standard precautions are necessary for the hospitalized child.

TETANUS

Tetanus is an acute, often fatal neurologic disease caused by the toxins produced by *Clostridium tetani.* Tetanus is rare in the United States but continues to be significant worldwide due to lack of routine immunization. It is characterized by increased muscle tone and spasm. *C. tetani* spores can live anywhere but are found most commonly in soil, dust, and feces from humans or animals, such as sheep, cattle, chickens, dogs, cats, and rats. The spores can enter the body through a wound that is contaminated, through a burn, or by injecting contaminated street drugs. Once it enters the body, an anaerobic environment allows it to multiply and a poisonous toxin is released.

There are four forms of tetanus. Neonatal tetanus is the most common worldwide, affecting newborns in the first week of life secondary to an infected umbilical stump or unsterile surgical technique during circumcision. Most women in the United States have been immunized and will pass the immunity to their fetus. Along with proper hygiene during delivery and adequate cord care, this makes this type rare in the United States, but in under-

developed countries it remains a significant problem. The second form is local tetanus. This rare form is characterized by local muscle spasms within the area of the wound. The third type is cephalic tetanus, which is associated with recurrent otitis media or head trauma. It is also rare and affects the cranial nerves, especially facial nerves. Generalized tetanus is the most common form and results in spasms that progress in a descending fashion beginning at the jaw. The most profoundly affected muscles are those of the neck and back. In the United States the fatality rate associated with tetanus has declined and cases are rare, but 3 out of 10 cases will result in death (Pickering, 2006). The general incubation period is 3 to 21 days; it averages 8 days. Recovery can be long and difficult, and children with tetanus may have to spend several weeks in the hospital in an intensive care setting. It has been suggested that the shorter the incubation period, the higher the risk of more severe illness and poorer prognosis. Complications associated with tetanus include breathing problems, fractures, elevated blood pressure, dysrhythmias, clotting in the blood vessels of the lung, pneumonia, and coma.

Therapeutic management is directed toward supporting respiratory and cardiovascular function. Tetanus immunoglobulin may be given as well as the tetanus vaccine. Removal of the offending organism, by débridement of the wound, may occur, and intravenous antibiotics such as metronidazole may be initiated. In severe cases, the child may require intensive nursing care with mechanical ventilation.

Nursing Assessment

Note history of initial signs such as headache, spasms, crankiness, and cramping of the jaw (lockjaw), which are followed by difficulty swallowing and a stiff neck. Tetanus progresses in a descending fashion to other muscle groups, causing spasms of the neck, arms, legs, and stomach; seizures may result. Document the presence of fever along with an elevated blood pressure and tachycardia. Opisthotonos may be noted due to severe spasms of the neck and back. The spasms or muscle contractions in children may be strong enough to result in fractures. The diagnosis of tetanus is based on the clinical findings of the history and physical examination.

Nursing Management

Nursing management focuses on observing for signs of respiratory distress. Provide a quiet environment with reduced external stimuli to decrease the incidence of spasms. Appropriately manage pain. Encourage adequate nutrition and hydration. Administer sedatives and muscle relaxants as ordered to reduce the pain associated with the muscle spasms and to prevent seizures. Encourage the parents to stay with their child. The child's mental status is unaffected by the disease, and therefore he or she is aware of what is happening. Efforts need to be made to reduce the child's anxiety and to provide reassuring, sympathetic care to the child and family.

Tetanus is a preventable but potentially fatal disease. Education is essential regarding the importance of receiving this routine immunization (refer to Chapter 30 for immunization schedule) as well as a booster every 10 years. Instructing parents on proper wound care can also help prevent tetanus. All wounds should be cleaned thoroughly and a proper antiseptic used. If a wound is deep and contamination is suspected, the child should be seen by a health care professional. If it has been more than 5 years since the last tetanus dose, a booster may be needed. This can help to neutralize the poison and prevent it from entering the nervous system.

Viral Infections

Viruses are very small particles that infect cells. They cannot multiply on their own and require a living host, such as humans, animals, or plants. They can reproduce only by invading and taking over the host cells. Young children are highly sensitive to viruses, as their resistance is low and exposure is high. Viruses are hard to destroy without damaging or killing the living cells they infect; this is why drugs are not used to control them. Many viral diseases can be prevented by immunization, such as measles, rubella, varicella, mumps, and poliomyelitis (see Chapter 30 for more information on immunizations).

VIRAL EXANTHEMS

Many viral infections of the skin in childhood are called viral exanthems. **Exanthem** means rash or skin eruption. Viral exanthems of childhood often present with a distinct rash pattern that assists in the diagnosis of the virus. Table 36.4 discusses common childhood exanthems. Immunizations have led to a decrease in the incidence of certain viral exanthems, such as measles, rubella, and varicella.

Typically, children with viral exanthems are cared for at home, but there are times when a child may be hospitalized or may develop the disease while being hospitalized. Appropriate transmission-based precautions must be taken. Therapeutic management of the viral exanthems focuses on fever management and relief of discomfort.

Nursing Assessment

Obtain the history of the present illness, noting the onset of rash in relation to the onset of fever. Note accompanying symptoms such as respiratory complaints. Document known exposure to childhood diseases. Note immunization status. Inspect the skin for rash, noting the distribution, type, and extent of lesions. Table 36.4 describes the

(text continues on page 1124)

TABLE 36.4 COMMON VIRAL EXANTHEMS OF CHILDHOOD

Disease	Clinical Manifestations	Management/Complications	Nursing Implications
Rubella (German measles) • Caused by rubella virus • Transmitted by direct or indirect contact with droplets, primarily by nasopharyngeal secretions, but also in blood, stool, and urine. Also transmitted from mother to fetus. • Peak incidence during late winter and early spring • Incubation period: 14 to 23 days (usually 16 to 18) • Communicable 7 days before to 7 days after onset of rash 	• Lymphadenopathy (retroauricular, posterior cervical, postoccipital) 24 hours before the onset of the rash; lasting up to 1 week • Rash begins on face and spreads quickly down the neck, trunk, and extremities; disappears in same order it spread, usually by third day. On the second day the rash may appear pinpoint. Desquamation is minimal. • Mild pruritus. • Polyarthralgia and polyarthritis (rare in children but common in adolescents)	Usually mild and self-limiting • Treatment is mainly supportive. • Complications: Encephalitis and thrombocytopenia (rare) • Maternal rubella during pregnancy can result in miscarriage, fetal death, or congenital malformations.	• Comfort measures such as antipyretics, antipruritics, and analgesics for joint pain • Contact precautions for the duration of the illness in the hospitalized child • Avoid exposure to pregnant women.
Rubeola (measles) • Caused by measles virus • Transmitted by direct or indirect contact with droplets, primarily by nasopharyngeal secretions, but also blood and urine. Highly contagious. • Incubation period: 10 to 12 days • Communicable 1 to 2 days before the onset of symptoms (3 to 5 days before onset of rash) until 5 days after rash has appeared 	• Prodromal phase: 3 to 5 days, consisting of fever, cough, coryza, conjunctivitis • Followed by Koplik spots • Erythematous maculopapular rash appears 3 to 4 days after the onset of the prodromal phase.	• Treatment is mainly supportive, including antipyretics, bed rest, adequate fluid intake. • Possible vitamin A supplementation in children 6 months to 2 years hospitalized for measles or its complications or those with immunodeficiency (Kliegman et al., 2007) • Complications: otitis media, pneumonia, croup, and diarrhea common in young children; acute encephalitis	• Comfort measures, such as antipyretics and antipruritics • Clean eyes with warm, moist cloth to remove secretions. • Cool mist humidification to alleviate coryza and cough • Droplet precautions until fifth day of rash

Varicella zoster (chickenpox)

- Caused by varicella zoster virus, human herpes virus 3
- Highly contagious. Transmitted by direct contact with infected persons' nasopharyngeal secretions or via airborne spread, to a lesser degree by contact with unscabbed lesions. Also transmitted from mother to fetus.
- Peak incidence late fall, winter, and spring
- Incubation period: 14 to 21 days, usually 14 to 16
- Communicable 1 to 2 days before onset of rash until all vesicles have crusted over (about 3 to 7 days after onset of rash)

- Prodromal symptoms (fever, malaise, anorexia, headache, mild abdominal pain) may be present 24 to 48 hours before the onset of the rash.
- Lesions often appear first on scalp, face, and trunk; initially intensely pruritic erythematous macules that evolve to papules and then form clear, fluid-filled vesicles.
- Vesicles eventually erupt, and then lesions scab and crust. A variety of lesions are present at one time.
- More severe in adolescents and adults than in young children

- Usually self-limiting; treatment is mainly supportive: fever reduction, antipruritics, and skin care to prevent infection of lesions.
- Antiviral therapy and varicella zoster immune globulin may be used in those considered to be at high risk (immunocompromised, pregnant women, and newborns exposed to maternal varicella). Routine antiviral therapy is not recommended for the treatment of uncomplicated varicella infection in otherwise healthy children.
- Complications: bacterial superinfection of skin lesions, thrombocytopenia, arthritis, hepatitis, cerebellar ataxia, encephalitis, meningitis, pneumonia, glomerulonephritis, congenital infection and life-threatening perinatal infection
- Lifelong latent infection occurs; reactivation results in herpes zoster (shingles), uncommon in childhood.

- Comfort measures, such as antipyretics and antipruritics
- Airborne and contact precautions in the hospitalized child for a minimum of 5 days after onset of rash and as long as vesicular lesions are present
- For those with exposure to susceptible persons, airborne and contact precautions, from 8 to 21 days after exposure
- Children may return to school or childcare once lesions have crusted.

(continued)

TABLE 36.4 COMMON VIRAL EXANTHEMS OF CHILDHOOD (continued)

Disease	Clinical Manifestations	Management/Complications	Nursing Implications
Exanthem subitum (roseola infantum or sixth disease) • Caused by human herpes virus 6 (HHV-6); less frequently human herpes virus 7 (HHV-7) • Transmission mode: little is known but suspected to be from saliva of infected person and enters the host through the oral, nasal, or conjunctival mucosa • Peak incidence age 6 to 15 months • Incubation period: 5 to 15 days, average of 10 days • Communicability is unknown, but most likely contagious during febrile stage 	• Prodromal phase: usually asymptomatic but may include upper respiratory signs • Clinical illness: high fever ranging from 37.9° to 40°C (101° to 106°F) for 3 to 5 days; resolves abruptly; rash appears 12 to 24 hours later, lasting about 1 to 3 days	• Course is generally benign. • In children who are uncomfortable or irritable or have a history of febrile seizures, antipyretics may be warranted. • Complications: HSV-6 may be responsible for some febrile seizures, encephalitis and meningoencephalitis (rare).	• Comfort measures, such as antipyretics, antipruritics • Standard precautions are sufficient in the hospitalized child.
Erythema infectiosum (fifth disease) • Caused by human parvovirus B19 • Transmitted by large droplet spread from nasopharyngeal viral shedding or percutaneous exposure to blood and blood products. Also transmitted from mother to fetus. • Peak incidence late winter and early spring. • Incubation period: 4 to 21 days, average 16 to 17 days	• Prodromal phase: mild symptoms, low-grade fever, headache, mild upper respiratory infection • Characteristic rash occurs in three stages: • Begins with erythematous flushing often described as “slapped-cheek” appearance, often with circumoral pallor	• Usually benign and self-limited; supportive treatment is all that is needed. • Blood transfusion may be necessary in children with aplastic crisis. • Complications: arthritis and arthralgia • May result in fetal loss, hydrops fetalis in pregnant woman	• Comfort measures, such as antipyretics, antipruritics • Droplet precautions are required in the hospitalized child. • Inform pregnant women (including health care workers) of the potential risks to the fetus and preventive meas-

• Communicability is uncertain, but most children are no longer infectious by the time the rash appears and diagnosis is made, so isolation or exclusion from school, once child is diagnosed, is unnecessary (those with aplastic crisis may be communicable up to 1 week after onset of symptoms and those who are immunosuppressed with chronic infection and severe anemia may be communicable for months to years). 	• Spreads to trunk • Moves peripherally, appearing as a maculopapular, lace-like appearance; often pruritic • Palms and soles are usually spared. Rash fluctuates in intensity and will disappear and reappear with environmental changes such as exposure to sunlight. • Resolves spontaneously over 1 to 3 weeks • Children with preexisting anemias may develop aplastic crisis (will have fever, malaise, myalgia, but usually no rash).		ures to decrease these risks (strict infection control practices, not caring for those likely to be contagious). The CDC does not recommended routine exclusion from a workplace where an outbreak is occurring.
Hand, foot and mouth disease, or herpangina (if only mouth involvement) • Caused by Coxsackie A viruses (esp. A16). Transmitted by direct contact with infected fecal, oral secretions; spread mostly through saliva. • Peak incidence during spring and summer, particularly in children who wear diapers (1- to 4-year-olds) • Most common during spring and summer • Incubation period: 3 to 6 days • Communicable from time of infection until fever resolves; virus is shed for several weeks after the infection begins.	• High fever usually occurs first. • Vesicles on tongue and oral mucosa erode to shallow ulcers; vesicles on hands and feet are football-shaped, with erythematous rims. • Extensive mouth lesions may lead to anorexia, dehydration, and drooling.	• Usually mild and self-limiting, resolving within 1 week • Treatment is mainly supportive. • Complications: dehydration, meningitis, encephalitis, and pulmonary edema	• Contact precautions and good hand hygiene are necessary. • Encourage oral fluids of preference, Popsicles. • Provide analgesics as needed.

rash as well as accompanying symptoms for each of the viral exanthems.

Nursing Management

Nursing management of viral exanthems focuses on fever reduction, relief of discomfort, and protection of skin integrity. Encourage hydration. Administer antipyretics and antipruritics as needed (refer to Drug Guide 36.1). Nonpharmacologic interventions to reduce fever, such as tepid sponging and cool compresses, may be used. Refer to Nursing Care Plan 36.1 for additional information; care should be individualized based on the child's and family's response to the illness.

▶ *Take* NOTE!

Trim the child's fingernails or cover hands with mitts, gloves, or socks (which work well with younger infants and children) if the rash itches to help prevent breaks in the skin, which can lead to discomfort and infection.

MUMPS

Mumps, a contagious disease caused by Paramyxovirus, is characterized by fever and parotitis (inflammation and swelling of the parotid gland). Mumps is spread via contact with infected droplets. Infected individuals are contagious for 1 to 7 days prior to onset of symptoms and for 7 to 9 days after parotid swelling begins. The American Academy of Pediatrics recommends immunization against mumps for all children. Mumps occurs most frequently in unimmunized children between 5 and 19 years of age. About one third of all infected prepubertal boys also develop orchitis (inflammation of the testicle). Complications of mumps include meningoencephalitis with seizures and auditory neuritis, which can result in deafness. Therapeutic management is supportive.

Nursing Assessment

Note history of exposure to infected individuals as well as immunization status. Determine history of low-grade fever and onset and progression of parotid swelling. History may also include malaise, anorexia, headache, and abdominal pain. The parotid swelling is easily observed as swelling of the neck either bilaterally or unilaterally (Fig. 36.3). In boys, note orchitis. The diagnosis is usually based on the history and clinical presentation, but serum may be tested for the presence of mumps immunoglobulin G (IgG) or immunoglobulin M (IgM) **antibody**.

FIGURE 36.3 Parotitis associated with mumps.

Nursing Management

Nursing management of mumps is primarily supportive. Acetaminophen is used for fever management, and occasionally narcotic analgesics are required for pain management. Oral fluids are encouraged to prevent dehydration. If orchitis is present, ice packs to the testicles and gentle testicular support may be helpful. Hospitalized children should be confined to respiratory isolation to prevent spread of the disease. Infected children are considered no longer contagious 9 days following onset of parotid swelling. Current recommendations include first mumps immunization by 15 months of age, followed by a second vaccine between 4 and 6 years of age (see Chapter 30 for information on mumps vaccination).

▶ *Take* NOTE!

In recent years mumps outbreaks have occurred, mainly on college campuses. The mumps vaccine is not 100% effective, and mumps infection can occur in vaccinated individuals. Per the CDC (2006), one dose of MMR prevents 80% of cases and two doses prevent approximately 90% of cases. During an outbreak it is essential to define the population at risk and transmission setting, identify and isolate suspected cases, and identify and vaccinate susceptible individuals (CDC, 2006).

POLIOMYELITIS

Poliomyelitis is an infection caused by the highly infectious poliovirus, which is an enterovirus. The virus invades the central nervous system and can produce total paralysis. Transmission occurs through direct or indirect contact. The poliovirus is spread most commonly via the fecal-to-oral or oral-to-oral route. Polio most commonly occurs in young children and is also referred to as infantile paralysis. This disease is rare due to effective immunization programs but is still seen in developing countries in the eastern Mediterranean region, India, and Africa.

Nursing Assessment

Initial signs and symptoms include fever, fatigue, headache, vomiting, neck stiffness, and limb pain. Symptoms then progress to tremors of the extremities and possible paralysis. Kernig's sign will be positive and deep tendon reflexes will be hyperactive initially and then diminished. Paralysis is asymmetric and generally affects the legs more than the arms. Respiratory problems can occur if the respiratory center of the brain is involved. The poliovirus can be isolated in feces or the pharynx of infected individuals, and cerebrospinal fluid evaluation generally shows elevated leukocytes and protein.

Nursing Management

Nursing management is aimed at providing supportive care, focusing on maintaining respiratory status and nutritional status until the illness has run its course. Bed rest will usually be ordered, so skin care is a priority. Maintaining self-care and mobility are also important nursing functions. Long-term care providing therapy and bracing to strengthen muscles may be needed during and after hospitalization.

No cure for polio exists, but it can be prevented by the polio vaccine, which is routinely administered in developed countries (refer to the immunization schedule in Chapter 30). Oral polio vaccine (OPV) is a live strain, and thus the virus is shed in the stool for up to 6 weeks after immunization, leading to the risk for vaccine-acquired polio in caregivers. For this reason, OPV has been replaced by inactivated polio vaccine (IPV), an injectable form, in the United States. OPV is still used in developing countries, however, so immigrants or travelers whose children were recently immunized in their home country should take precautions if they are immunocompromised or unvaccinated. Areas where polio is endemic, including Afghanistan, Egypt, India, Niger, Nigeria, and Pakistan, agreed to a massive immunization campaign in 2004 and hope to make polio the first eradicated disease of the 21st century (Stephenson, 2004).

RABIES

Rabies is a preventable viral infection of the central nervous system. It is transmitted to other animals and humans through close contact with the saliva of a rabid animal, usually by a bite. The number of cases of rabies has steadily declined in the United States. It is rare in the United States and Western Europe due to routine vaccination of domestic animals, such as dogs, and the availability of effective postexposure prophylaxis. Now most cases of rabies in these areas are due to wild animals such as raccoons, skunks, bats, and foxes. Rabies continues to be a major health problem in other parts of the world, especially in areas where dogs are not controlled.

Most cases of rabies occur in children less than 15 years of age, and most human deaths occur in developing countries. Children have an increased susceptibility to rabies due to their fearlessness around animals, eagerness to play with animals, shorter stature, and inability to protect themselves. The incubation period for rabies is extremely variable and can range from 20 to 180 days, with the peak at 30 to 60 days (Kliegman et al., 2007). The incubation period tends to be shorter in children. Once symptoms of rabies have developed the prognosis is poor: death usually occurs within days of the onset of symptoms. Prevention is of paramount importance, and eliminating infection in animal vectors is essential. Successful animal vaccination and animal control campaigns in the United States have led to a very low rate of human rabies cases. Rabies among dogs in the United States has been virtually eliminated. Recently, rabies transmitted from other animals, especially bat bites, has become a cause for concern.

The decision to provide postexposure prophylaxis can be complex. The local health department should be contacted. Several factors need to be considered, such as local epidemiology, type of animal involved, availability of the responsible animal for testing or quarantine, and the circumstances of the exposure, such as a provoked versus an unprovoked attack. In the United States, concurrent use of passive and active immunoprophylaxis is recommended. It consists of a regimen of one dose of immune globulin and five doses of human rabies vaccine over a 28-day period. Rabies immune globulin and the first dose of rabies vaccine should be given as soon as possible after exposure, ideally within 24 hours. Additional doses of rabies vaccine should be given on days 3, 7, 14, and 28 after the first vaccination. Rabies immune globulin is infiltrated into and around the wound, with any remaining volume administered intramuscularly at a site distant from the vaccine inoculation. Human rabies vaccine is administered intramuscularly into the anterolateral thigh or deltoid, depending on the age and size of the child. Administration into the gluteus muscle should be avoided, since this site has been associated with vaccine failure (Kliegman et al., 2007).

Nursing Assessment

Note history of an animal bite, especially if it was unprovoked, and exposure to bats. Document history of early symptoms of rabies infection, which are nonspecific and flu-like, such as fever, headache, and general malaise. The child may complain of pain, pruritus, and paresthesia at the bite site. As the virus spreads to the central nervous system, encephalitis develops. The disease will have progressive neurologic manifestations, which may include insomnia, confusion, anxiety, changes in behavior, agitation or excitation, hallucinations, hypersalivation, dysphagia, and hydrophobia, which results from aspiration when swallowing liquid or saliva. In some cases progressive paralysis may be present. The client may have periods of lucidity alternating with these neurologic changes.

Laboratory testing may include hair and saliva specimens from which the virus may be isolated. Serum and cerebrospinal fluid can be tested for antibodies to the rabies virus. Direct fluorescent antibody testing can be done to diagnose rabies in a suspected animal. The test can only be done postmortem and requires brain tissue from the potentially rabid animal.

Nursing Management

Few people survive once symptomatic rabies infection develops. Intensive supportive care is required, but recovery is extremely rare. Therefore, it is vital to educate children and families about the importance of seeking medical care after any animal bite to prevent death from rabies infection. Also, teach children to avoid wild animals, stray animals, and any animal with unusual behavior. Teach children not to provoke or attempt to capture wild or stray animals.

Regardless of whether immunoprophylaxis is initiated, appropriate wound management is necessary in all victims of a bite from a potentially rabid animal. This includes a thorough cleansing of all wounds with soap and water. Irrigation of wounds for at least 10 minutes with a virucidal agent, such as povidone–iodine solution, is recommended (Kliegman et al., 2007).

When caring for a child requiring postexposure prophylaxis, provide support and education to the child and family. Due to the seriousness and urgency surrounding this disease and treatment, the child and family are often very frightened. Consider comfort measures, such as EMLA cream and positioning, when giving immunization.

Vector-Borne Infections

Children are at a particular risk for contracting vector-borne diseases, which are diseases transmitted by ticks, mosquitoes, or other insect vectors (Table 36.5). Young children are unaware of the health risks around them and cannot take protective measures. Their immature immune system leads to a decreased capacity to resist vector-borne diseases. These diseases can be severe and even fatal, though most are treatable if identified early. Many times the child presents initially with nonspecific symptoms. Coupled with the fact that there are few definitive diagnostic tests available, this can lead to difficulty in promptly recognizing and treating these diseases.

Tick-borne diseases are the most common vector-borne illnesses in the United States. Two of the most common will be covered below.

LYME DISEASE

Lyme disease, the most common vector-borne disease in the United States, is caused by the spirochete *Borrelia burgdorferi.* It is transmitted to humans via the bite of an infected blacklegged tick. It has been reported in more than 50 countries and is seen in three distinct regions in the United States. Most cases occur in the Northeast, from southern Maine to northern Virginia. Cases have also been reported in the upper Midwest and the West Coast, especially northern California, but with less frequency. Most cases are seen between April and October. Lyme disease can affect any age group, but the incidence is highest among children 5 to 10 years of age (Kliegman et al., 2007). The prognosis for recovery in children who are treated is excellent.

Therapeutic Management

In most cases Lyme disease can be cured by antibiotics, especially if they are started early in the illness. Doxycycline is the drug of choice for children older than 8 years. Because it can cause permanent discoloration of the teeth, children younger than 8 should be treated with amoxicillin. For clients allergic to penicillin, cefuroxime or erythromycin can be used. Duration of treatment is usually 14 to 21 days.

Nursing Assessment

The clinical signs of Lyme disease are divided into three stages: early localized, early disseminated, and late disease. Untreated clients may progress through the three stages or may present with early disseminated or late disease without having any symptoms of the earlier stages. If children are treated in the early stage, it is uncommon to see them with late disease. Nursing assessment for Lyme disease includes an accurate health history as well as physical examination.

Health History

Explore the health history for a tick bite. Document onset of rash. In early localized disease, the rash usually occurs 7 to 14 days after the tick bite (though it can appear 3 to 32 days after the bite). In early disseminated disease, the

TABLE 36.5 **OTHER VECTOR-BORNE ILLNESSES**

Disease	Causative Organism	Geographic Distribution	Vector of Transmission	Manifestations
Mediterranean spotted fever (boutonneuse fever)	*Rickettsia conorii*	Africa, Mediterranean region, India, Middle East	Tick bite	• Fever, headache, maculopapular rash • Eschar may be present at tick bite.
Rickettisial pox	*Rickettsia akari*	Northeastern cities in United States, Europe and Asia, mainly urban settings	Mouse mite bite	• Bite becomes a papule, then pustule, then ulcerates and forms eschar at site. • Fever, local adenopathy, headache, myalgia, maculopapular rash that may become vesicular
Epidemic typhus	*Rickettsia prowazekii*	Africa, South America, Central America, Mexico, Asia; occasional cases seen in United States	Louse feces (typically from the body louse) that are rubbed into broken skin or mucous membranes. Cases in United States associated with louse or flea of flying squirrel.	• Abrupt onset of high fever, chills, and myalgia with severe headache and malaise • Rash appears 4 to 7 days after onset of symptoms, beginning on the trunk and spreading to the extremities. • Maculopapular rash becomes petechial or hemorrhagic, then develops brown pigmented areas. • Changes in mental status may occur. • Flying squirrel–related disease typically presents as a milder illness.
Endemic typhus (murine typhus)	*Rickettsia typhi* and *Rickettsia felis*	Worldwide, especially warm coastal ports. In United States, most prevalent in southern Texas and southern California.	Rat flea or cat flea feces	• Headache, myalgia, and chills that slowly worsen • Fever for 10 to 14 days • Rash appears after 3 to 8 days; it is macular or maculopapular with sparse lesions and no hemorrhage.

(continued)

TABLE 36.5 OTHER VECTOR-BORNE ILLNESSES (continued)

Disease	Causative Organism	Geographic Distribution	Vector of Transmission	Manifestations
Scrub typhus	*Orientia tsutsugamushi*	Southern Asia, Japan, Indonesia, Australia, Korea, Asiatic Russia, India, China	Chigger bite	• Possible necrotic eschar at site of bite, fever, headache, myalgia, cough, and gastrointestinal symptoms • Lymphadenopathy, maculopapular rash on trunk and extremities.
Ehrlichioses	3 pathogens: *Ehrlichia chaffeensis, Ehrlichia anaplasma, Ehrlichia ewimgii*	Mostly in southeastern and south-central United States	Tick	• Fever with clinical signs similar to Rocky Mountain spotted fever. Rash is less commonly associated. • May also present with leukopenia, anemia, and hepatitis
Q fever	*Coxiella burnetii*	Worldwide	Inhalation of infected aerosols, ingestion of contaminated dairy products	• Most cases are initially asymptomatic. Occurs in two forms: • Acute: follows initial exposure and presents with abrupt onset of fever, chills, weakness, headache, and loss of appetite • Chronic: occurs years after initial exposure and may present with endocarditis (in clents with underlying heart disease), hepatitis, or fever of unknown origin
Malaria	*Plasmodium* (four species exist that infect humans: *P. falciparum, P. vivax, P. ovale, P. malariae*)	Endemic in tropical areas of the world. Highest risk in sub-Saharan Africa, Papua New Guinea, the Solomon Islands, and Vanuatu Other areas of risk: Haiti and Indian subcontinent	Bite of *Anopheles* species of mosquito	• High fever with chills, rigors, sweats, and headache, which may be paroxysmal • Nausea, vomiting, diarrhea, cough, arthralgia, abdominal and back pain may also occur. • Anemia and thrombocytopenia with pallor and jaundice may be seen. • May occur in a cyclic pattern, and depending on the species fever may occur every other day or every third day.

rash usually begins 3 to 5 weeks after the tick bite. Note complaints of fever, malaise, mild neck stiffness, headache, fatigue, myalgia, and arthralgia or pain in the joints. In late disease, note recurrent arthritis of the large joints, such as the knees, beginning weeks to months after the tick bite. The child with late disease may or may not have a history of earlier stages of the disease, including erythema migrans.

Physical Examination

Observe for a rash. Early local disease is characterized by a ring-like rash at the site of the tick bite (erythema migrans) (Fig. 36.4). If untreated, the rash gradually expands and will remain for 1 to 2 weeks. Early disseminated disease should be suspected if multiple areas of erythema migrans are found. The multiple lesions are usually smaller than the primary lesions. Note cranial nerve palsies (especially cranial nerve VII), conjunctivitis, or signs of meningeal irritation, which occur in early disseminated disease.

Laboratory and Diagnostic Testing

Immunoglobulin-specific antibody tests may not be positive in the early stage of the disease but may be useful in the later stages. The CDC recommends a two-step test: a sensitive enzyme immunoassay (EIA) or immunofluorescent assay (IFA) followed by a Western immunoblot. If these are negative, no further testing is indicated.

Nursing Management

Administer antibiotics as ordered. In the hospitalized client, no transmission-based precautions are necessary. Educate the client and family on the importance of taking the antibiotic as directed and finishing all the medicine. Another important nursing function is educating the client, family, and community on prevention measures (Box 36.5). For infection to occur, the tick must be attached for 24 to 48 hours, so prompt removal of ticks is essential to the prevention of Lyme disease. Teaching Guidelines 36.2 gives information on tick removal. A vaccine was licensed in 1998 by the U.S. Food and Drug Administration for persons ages 15 to 70, but it has since been withdrawn due to low demand.

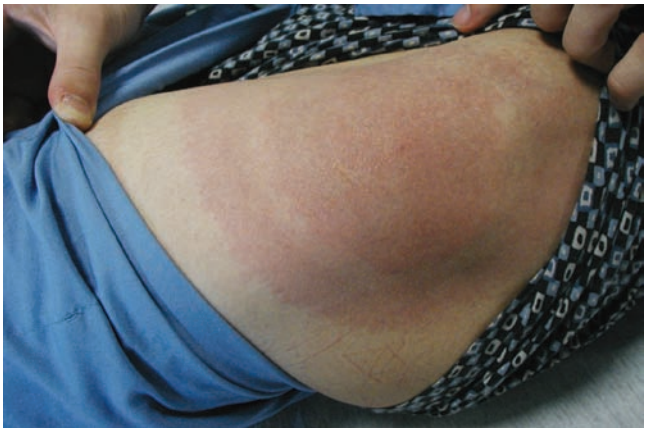

FIGURE 36.4 Erythema migrans, a ring-like rash at the site of the tick bite, occurs in Lyme disease.

BOX 36.5 Prevention of Tick-Borne Illnesses

- Wear appropriate protective clothing when entering tick-infested areas. Clothing should fit tightly around wrists, waists, and ankles. Tuck pants into socks if possible.
- After leaving the area, check for ticks and remove them promptly.
- Insect repellent may provide temporary relief but may produce toxicity, especially in children, if used frequently or in large doses.

ROCKY MOUNTAIN SPOTTED FEVER

Rocky Mountain spotted fever (RMSF) is the most severe and frequently reported rickettsial illness in the United States. A rickettsia is a bacteria of the genus Rickettsiae; these bacteria are carried as a parasite by many ticks, fleas, and lice and cause disease in humans. RMSF is caused by the bacteria *Rickettsia rickettsii.* The American dog tick and Rocky Mountain wood tick are the primary vectors, although others have been implicated. RMSF can be fatal without prompt and appropriate treatment. Most cases occur between April and September.

RMSF occurs throughout the United States; its name is derived from the fact that it was discovered in the Rocky Mountain region, though few cases are found there today. RMSF is more common in the coastal Atlantic states, with

TEACHING GUIDELINES 36.2

Tick Removal

- Use fine-tipped tweezers.
- Protect fingers with a tissue, paper towel, or latex gloves.
- Grasp tick as close to the skin as possible and pull upward with steady, even pressure.
- Do not twist or jerk the tick.
- Once the tick is removed, clean site with soap and water and wash your hands.
- Save the tick for identification in case the child becomes sick. Place in a sealable plastic bag and put it in your freezer. Write date of bite on the bag.

HEALTHY PEOPLE 2010

Objective	Significance
Reduce Lyme disease	• Educate the client, family, and community on prevention measures (refer to Box 36.5).

the highest incidence in North Carolina and Oklahoma. It occurs in all age groups but most frequently in children, with the peak incidence in 5- to 9-year-olds (Kliegman et al., 2007).

Complications of RMSF include noncardiogenic pulmonary edema, cerebral edema, and multiorgan damage. Long-term neurologic involvement, such as partial paralysis of the lower extremities, hearing loss, loss of bladder and bowel control, movement disorders, and language disorders, may be seen, especially in clients with severe illness who require long hospital stays.

Therapeutic Management

The fatality rate from RMSF has decreased with the widespread use of antimicrobial therapy. However, delays in diagnosis and therapy are significant factors associated with severity of disease and death. In most cases RMSF resolves rapidly with appropriate antibiotic therapy, especially if it is started early. Treatments of choice are tetracyclines, such as doxycycline, and chloramphenicol. Chloramphenicol is the preferred drug in children less than 9 years old due to the risk of teeth staining, though some clinicians use doxycycline to treat children less than 9 because tooth discoloration is dose-dependent and children less than 9 are unlikely to need multiple doses (Kliegman et al., 2007). Length of treatment is 5 to 10 days.

Nursing Assessment

Note history of early signs of RMSF, such as sudden onset of fever, headache, malaise, nausea and vomiting, muscle pain, and anorexia. The incubation period varies from 2 to 14 days, with the average being around 7 days after the tick bite. Late signs include a rash, usually seen 2 to 5 days after the onset of the fever, abdominal pain, joint pain, and diarrhea. Inspect the skin for a rash, which starts as small, pink, macular, non-itchy, blanchable spots on the wrists, forearms, and ankles. The rash then spreads rapidly over the entire body, including the soles and palms. After several days the rash will appear red, spotted and petechial, or hemorrhagic (Fig. 36.5). Approximately 10% to 15% of those with RMSF do not have a rash (Kliegman et al., 2007). Laboratory findings may include a low leukocyte count, low or decreasing platelet count, and hyponatremia. Biopsy of the rash with immunofluorescent assay and serologic tests may also be used.

FIGURE 36.5 Rash associated with Rocky Mountain spotted fever.

Nursing Management

Nursing management is similar to that for Lyme disease. Educate the family about completing the antibiotic course, preventing tick bites, and appropriate tick removal (refer to Box 36.5 and Teaching Guidelines 36.2).

Parasitic and Helminthic Infections

Parasites are organisms larger than yeast or bacteria that can cause infection. They live in or on a host. Parasites receive nourishment from the host without benefiting or killing the host. Parasites frequently seen in children are scabies and head lice. A helminth is a parasitic intestinal worm. Helminthic infections seen in children include pinworms, roundworms, and hookworms. Children are at an increased risk for parasitic or helminthic infections due to poor hygiene practices: they are typically more careless about handwashing and they tend to put things in their mouths and share toys and objects with other children.

Nursing Assessment and Management

Parents are often embarrassed when they find out that their child has a parasitic or helminthic infection. Reassure them that these infections can occur in any child. Tables 36.6 and 36.7 give nursing assessment and management information related to specific common parasitic and helminthic infections in children.

(text continues on page 1135)

TABLE 36.6 COMMON PARASITIC INFECTIONS IN CHILDREN

Infection/Causative Organism	Transmission	Clinical Manifestations	Diagnosis/Treatment	Isolation/Control Measures
Pediculosis capitis (head lice) Caused by *Pediculus humanus capitis* (head louse)	Direct contact with hair of infested people, less commonly with personal belongings, such as combs and hats, of those infested Incubation period from laying of eggs to hatching of nymph is 6 to 10 days; adult lice will appear 2 to 3 weeks later.	Extreme pruritus is the most common symptom. Adult eggs (nits) or lice may be seen, especially behind the ears and at the nape of the neck.	Diagnosis by identification of eggs, nymph, and lice with the naked eye is possible; adult lice are rarely seen. Treatment: Washing hair with a pediculicide such as permethrin, lindane, malathion. Careful instructions on proper use of any product should be given and strict adherence to application instructions encouraged. Detection of living lice 24 hours after treatment suggests incorrect use, a very heavy infestation, reinfestation, or resistance to treatment. Removal of nits after treatment is not necessary to prevent spread but may be done for aesthetic reasons (Pickering, 2006).	Contact precautions Control measures: Household and other close contacts should be examined and if infested treated. Bedmates should be treated prophylactically. Children should not be excluded or sent home from school. Most children can be treated effectively without treating their clothing and bedding. If needed, dry-cleaning clothing or simply sealing it in a plastic bag for 10 days is effective. Disinfection of headgear, pillowcases, and towels by washing in hot water and drying on the hot cycle may be helpful. Soak combs and hairbrushes in pediculicide, shampoo, or hot water (Pickering, 2006). Lice infestation is not a sign of poor hygiene; all socioeconomic groups are affected.
Pediculosis pubis (pubic lice) Caused by *Phthirus pubis*	Transmission usually occurs through sexual contact; also can be through contaminated items such as towels.	Pruritus of anogenital area; other hairy areas of the body, including eyelashes, eyebrows, axilla, beard, can be affected	Diagnosis by identification of eggs, nymph, and lice with the naked eye is possible; adult lice are rarely seen. Same as treatment with pediculicides to treat head lice. Retreat 7 to 10 days later. Use petroleum oil to treat eyelashes and eyebrows.	Contact precautions All sexual contacts should be treated.

(continued)

TABLE 36.6 COMMON PARASITIC INFECTIONS IN CHILDREN (continued)

Infection/Causative Organism	Transmission	Clinical Manifestations	Diagnosis/Treatment	Isolation/Control Measures
Scabies Caused by *Saracoptes scabiei*	Incubation period from laying of eggs to hatching of nymph is 6 to 10 days; adult lice will appear 2 to 3 weeks later. Transmission usually occurs through prolonged, close personal contact. Incubation period in those without previous exposure is 4 to 6 weeks. People who were previously infested can develop symptoms in 1 to 4 days.	Intense pruritus (especially at night) with presence of erythematous, papular rash with excoriations. The lesions are generally distributed but often are concentrated on the hands and feet and in body folds. May be found on head and neck. In infants and young children and those who are immunocompromised, the rash may include vesicles, pustules, or nodules.	Diagnosis can be made by a history of itching (especially at night), classic rash, and reports of itching in household or sexual contacts. Mites can be seen on microscopic examination of skin scrapings to confirm diagnosis. Treatment: A scabicide, such as permethrin or lindane, should be applied to the entire body below the head. Treatment of infants and young children should include the head, neck, and body. The cream is left on for a specified time (usually 8 to 14 hours) depending on the type of scabicide. Careful instructions on proper use of any product should be given and strict adherence to application instructions should be urged. Itching may not subside for several weeks, even after successful treatment.	Contact precautions. Prophylactic therapy for household members Bedding and clothing worn the 4 days prior to treatment should be laundered in hot water and dried on the hot cycle (mites do not survive more than 3 to 4 days without skin contact). Environmental disinfestation is unnecessary (Pickering, 2006).

TABLE 36.7 COMMON HELMINTHIC INFECTIONS IN CHILDREN

Infection/Causative Organism	Clinical Manifestations	Transmission	Diagnosis/Treatment	Isolation/Control Measures
Roundworm (ascariasis) Caused by *Ascaris lumbricoides,* common in temperate and tropical areas	Loss of appetite, nausea, vomiting, and abdominal pain may be seen. In significant infestation, partial or complete intestinal obstruction may occur. The more worms, the worse the symptoms.	Human feces are the major source of infected eggs. Hand to mouth is the usual route of transmission. The eggs are swallowed due to unclean hands or contaminated food. They pass into the intestine; larvae then hatch, penetrate the intestinal wall, enter the circulatory system, and migrate to any body tissue.	Diagnosis: Once female worms are in the intestine, eggs can be visualized by microscopic evaluation of the stool. Occasionally a worm may be visualized in vomit or stool. Treatment is with mebendazole, albendazole, or pyrantel pamoate.	• Standard precautions are sufficient. • Sanitary disposal of feces • Proper hand hygiene
Hookworm Caused by *Ancylostoma duodenale* (roundworm) (found mainly in Europe, Africa, China, Japan, India, and the Pacific Islands) and *Necator americanus* (roundworm) (found mainly in the Americas, Caribbean, Africa, Asia, and the Pacific)	Most often people are asymptomatic until significant worms are established. May see pruritic erythematous papular rash at entry site (referred to as ground itch) or pulmonary symptoms as the larvae migrate. One of the greatest concerns in chronic infection is anemia (microcytic hypochromic anemia) secondary to blood loss as the worms suck blood and juices from the intestines. This can lead to hypoproteinemia, edema, pica, and wasting. The infection may result in physical or mental retardation in children.	Hookworms are found in soil and enter the host through pores, hair follicles, and even intact skin (hands and feet are major sites of entry). The maturing larvae travel through the circulatory system into the lungs and then up the bron-chial tree and are swallowed with secretions. They then migrate into the intestinal tract and attach to the wall of the small intestines, where they feed and reproduce. Transmission via ingested soil has been seen with *Ancylostoma duodenale* only.	Diagnosis is made through microscopic examination of feces that reveals hookworm eggs. Treatment: Albendazole, mebendazole, and pyrantel pamoate. In children younger than 2, the World Health Organization recommends half the adult dose of albendazole or mebendazole (Pickering, 2006). Iron supplementation and possible blood transfusion in severe cases	• Standard precautions are sufficient. • Proper sanitation and disposal of feces • Treatment of all known infested people • Screening of high-risk individuals • Encourage the wearing of shoes and avoiding going barefoot.

(continued)

TABLE 36.7 COMMON HELMINTHIC INFECTIONS IN CHILDREN (continued)

Infection/Causative Organism	Clinical Manifestations	Transmission	Diagnosis/Treatment	Isolation/Control Measures
Pinworm Caused by *Enterobius vermicularis* (roundworm)	Some people are asymptomatic. May cause anal itching (pruritus ani), especially at night. Other clinical findings may include teeth grinding at night, weight loss, and enuresis.	Fecal–oral route directly, indirectly, or inadvertently by contaminated hands or shared toys, bedding, clothing, toilet seats Incubation period is 1 to 2 months or longer.	Diagnosis is made when adult worms are visualized in the perianal region; they are best viewed when the child is sleeping. Very few ova are present in stool, so examination of stool is not recommended. Transparent tape pressed to perianal area and then viewed under a microscope may reveal eggs. Three consecutive specimens should be obtained when the child first awakens in the morning. Treatment of choice is mebendazole, pyrantel pamoate, and albendazole, usually single doses and repeated in 2 weeks. All family members should be treated since transmission from person to person is very easy.	Standard precautions are sufficient. Reinfection occurs easily. Infected people should bathe in the morning, which will remove a large portion of the eggs. Frequent changing of underclothes and bedding. Personal hygiene measures such as keeping fingernails short, avoiding scratching of perianal area and nail biting. Good hand hygiene is the most effective preventive measure, especially after using the bathroom and before eating.

▶ *Take* NOTE!

The head louse is becoming increasingly resistant to pediculicides. This may lead parents to resort to home remedies. Parents need to be informed that these remedies are unproven and can be toxic.

As the nurse in a pediatric clinic, you receive a call from a frantic mother. She tells you, "The school sent my daughter home and told me she has lice! We are clean people! I don't understand how this could happen!" How would you address her concerns? Discuss the plan of care for this child. What education and interventions will be necessary to prevent the spread of pediculosis capitis?

Key Concepts

- Infants and young children are more susceptible to infection due to their immature immune system. Young children continue to have an increased risk for infections and communicable disorders because disease protection from immunizations is not complete.
- When obtaining blood cultures, follow aseptic technique and hospital protocol to prevent contamination. Obtain the specimen before administering antibiotics.
- When administering antipyretics, proper education must be given to caregivers on appropriate dosing, concentration, dosing interval, and use of proper measuring device.
- Promoting proper fluid balance and reducing temperature in a febrile child are important nursing interventions when caring for a child with an infection or communicable illness.
- Many childhood infectious and communicable diseases involve a rash. Rashes can be difficult to identify, so a thorough description and history from the caregiver is important.
- Sepsis, a systemic overresponse to infection resulting from bacteria, fungi, viruses, or parasites, can lead to septic shock. Any infant less than 3 months old with a fever or any child with a fever accompanied by extreme lethargy, unresponsiveness, or lack of facial expressions should be seen by a health care provider.
- Many bacterial and viral infections, such as diphtheria, tetanus, pertussis, mumps, measles, rubella, varicella, and poliomyelitis, can be prevented by vaccination.
- Children are at a particular risk for contracting vector-borne diseases, which are disease transmitted by ticks, mosquitoes, or other insect vectors. Two of the most commonly seen are Lyme disease and Rocky Mountain spotted fever.
- Viral exanthems of childhood often present with a distinct rash pattern that assists in the diagnosis of the virus. Common childhood exanthems include exanthem subitum (roseola infantum), rubella (German measles), rubeola (measles), varicella (chickenpox), and erythema infectiosum (fifth disease).
- Nurses play a key role in educating the public on the importance of immunizations.
- Health care providers need to remember and educate parents that fever is a protective mechanism the body uses to fight infection.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. Compared with adults, why are infants and children at an increased risk for infection and communicable diseases?
   a. The infant has had limited exposure to disease and is losing the passive immunity acquired from maternal antibodies.
   b. The infant demonstrates an increased inflammatory response.
   c. Cellular immunity is not functional at birth.
   d. Infants have an increased risk for infection until they receive their first set of immunizations.
2. A mother calls the clinic because her 2-year-old daughter has a rectal temperature of 37.8°C (100°F). She wonders how high a fever should be before she should give medications to reduce it. What is the best response by the nurse?
   a. "All fevers should be treated to prevent seizures."
   b. "Antipyretics should be used with any rise in temperature. They can help change the course of the infection."
   c. "Give your child aspirin when her fever is above 38°C (100.4°F)."
   d. "In a normal healthy child, if your child is not uncomfortable, fevers less than 39°C (102.2°F) do not require medication."
3. A neonate should be evaluated by a physician if which signs and symptoms are present?
   a. Acting fussier than normal
   b. Refusing the pacifier
   c. Rectal temperature above 38°C
   d. Mottling that is present during bathing
4. The public health nurse has been asked to provide information to local childcare centers on controlling the spread of infectious diseases. What is the best information the nurse can provide?
   a. The etiology of common infectious diseases
   b. Proper handwashing techniques
   c. The physiology of the immune system
   d. Why children are at a higher risk of infection than adults

CRITICAL THINKING EXERCISES

1. A 12-year-old boy presents with a very sore throat and fever. On assessment you find an erythematous rash on his face that feels like sandpaper. You obtain a throat culture, which is positive for group A streptococcus. What instructions would you give the parents regarding his care at home?
2. A 1-month-old infant is admitted to the hospital to rule out sepsis. What would be your priority nursing interventions?
3. A 4-year-old child presents with a fever and rash. What three of the following items should the nurse obtain during the health history?
   a. Immunization history
   b. Any exposure to communicable or infectious diseases
   c. Whether the child takes a daily vitamin
   d. Thorough description and history of the rash
   e. Mother's immunization history

STUDY ACTIVITIES

1. The 4-year-old presented in question 3 above was diagnosed with varicella zoster virus. Write a nursing care plan for a child with varicella.
2. You are asked to give a presentation to a group of adolescents on sexually transmitted infections, including transmission, symptoms, treatment, and prevention. What information would you include?
3. A child is brought to the school nurse with intense itching. Upon assessment the nurse finds an erythematous, papular rash with excoriations on the child's hands and feet. As suspected, the diagnosis of scabies is confirmed. What teaching is necessary for the parents, family, and classmates of the child?

CHAPTER 37

Nursing Care of the Child With a Neurologic Disorder

Antonio Chapman, 3 months old, has had increased irritability, poor sucking and feeding, and a fever for the past 24 hours. Today he is lethargic with a weak cry and is vomiting his feeds.

KEY TERMS

automatism
central nervous system (CNS)
cerebrospinal fluid (CSF)
clonic
decorticate posturing
decerebrate posturing
head circumference
intracranial pressure (ICP)
lumbar puncture (LP)
myelinization
myoclonus
neural tube
opisthotonic
postictal
status epilepticus
teratogen
tonic

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Compare how the anatomy and physiology of the neurologic system in children differs from adults.
2. Identify various factors associated with neurologic disease in infants and children.
3. Discuss common laboratory and other diagnostic tests useful in the diagnosis of neurologic conditions.
4. Discuss common medications and other treatments used for treatment and palliation of neurologic conditions.
5. Recognize risk factors associated with various neurologic disorders.
6. Distinguish among different neurologic illnesses based on the signs and symptoms associated with them.
7. Discuss nursing interventions commonly used for neurologic illnesses.
8. Devise an individualized nursing care plan for the child with a neurologic disorder.
9. Develop client and family teaching plans for the child with a neurologic disorder.
10. Describe the psychosocial impact of chronic neurologic disorders on children.

Wow

As long as nurses possess inner integrity, they will be able to handle their patient's life's challenges.

Neurologic disorders in children often have a devastating and lasting impact. Neurologic disorders can be divided into several categories, including structural disorders, seizure disorders, infectious disorders, trauma to the neurologic system, blood flow disruption disorders, and chronic disorders.

Nurses must be familiar with neurologic conditions affecting children in order to provide prevention, prompt treatment, guidance, and support to families. Neurologic disorders require acute interventions, but many times have long-lasting implications on the child's health and development. Due to the potentially devastating effects that neurologic disorders can have on children and their families, nurses need to be skilled in assessment and interventions in this area and must be able to provide support throughout the course of the illness and beyond.

Variations in Pediatric Anatomy and Physiology

Neurologic disorders can result from congenital problems as well as from infections or traumas. Certain neurologic conditions occur in children more often than adults and will affect their growth and development. Pediatric clients are at an increased risk for different neurologic problems than adults due to anatomic and physiologic differences.

Brain and Spinal Cord Development

Development of the brain and spinal cord occurs early in gestation, in the first 3 to 4 weeks, from the **neural tube**. Infection, trauma, **teratogens**, and malnutrition during this period can result in malformations in brain and spinal cord development and may affect normal **central nervous system (CNS)** development.

At birth, the cranial bones are not well developed and are unfused. Therefore there is an increased risk for fracture. The brain is highly vascular, leading to an increased risk for hemorrhage. Premature infants are at greater risk for brain damage; the more premature the infant, the greater the risk. The premature infant has more capillaries in the periventricular area, which is the brain tissue that lines the outside of the lateral ventricles. These capillaries are fragile and at greater risk for rupture, leading to intracranial bleeding. Also, because the cranium is very soft in the preterm infant, external pressure can change its shape and cause increased pressure in areas of the brain and possible hemorrhage.

The sutures and fontanels present in the newborn help make the skull more flexible and help to accommodate for brain growth that continues after birth. Closure of the fontanels too early or too late can be indicative of problems with brain growth. The child's spine is very mobile, especially the cervical spine region, resulting in a high risk for cervical spine injury.

Nervous System

The development of the nervous system is complete but immature at birth. The infant is born with all the nerve cells that he or she will have throughout life. However, myelinization of these nerves is incomplete. The speed and accuracy of nerve impulses increases as **myelinization** increases. This process accounts for the acquisition of fine and gross motor movements and coordination in early childhood. Myelinization proceeds in the cephalocaudal direction. For example, infants are able to control the head and neck before the trunk and extremities.

The immaturity of the CNS in preterm infants can result in delayed development of motor skills. Premature newborns may have difficulty coordinating sucking and swallowing, leading to feeding and growth issues. Also, episodes of apnea can be problematic in the preterm newborn due to the underdevelopment of the nervous system.

Head Size

The head of the infant and young child is large in proportion to the body. The head of an infant accounts for a quarter of the body height; in adults it accounts for one eighth of the body height (Fig. 37.1). In addition, the infant's and child's neck muscles are not well developed. Both of these differences lead to an increased incidence of head injury from falls. The head is the fastest growing body part during infancy and continues to grow until the child is 5 years old.

Common Medical Treatments

A variety of interventions, including medical treatments and medications, are used to treat neurologic illness in children. Most of these treatments will require a physician's order when the child is hospitalized. The most common treatments and medications used for neurologic disorders are listed in Common Medical Treatments 37.1 and Drug Guide 37.1.

NURSING PROCESS OVERVIEW FOR THE CHILD WITH A NEUROLOGIC DISORDER

Care of the child with a neurologic disorder includes assessment, nursing diagnosis, planning, interventions, and evaluation. There are a number of general concepts related to the nursing process that can be applied to the management of neurologic disorders. From a general understanding of the care involved for a child with neurologic dysfunction, the nurse can then individualize the care based on client specifics.

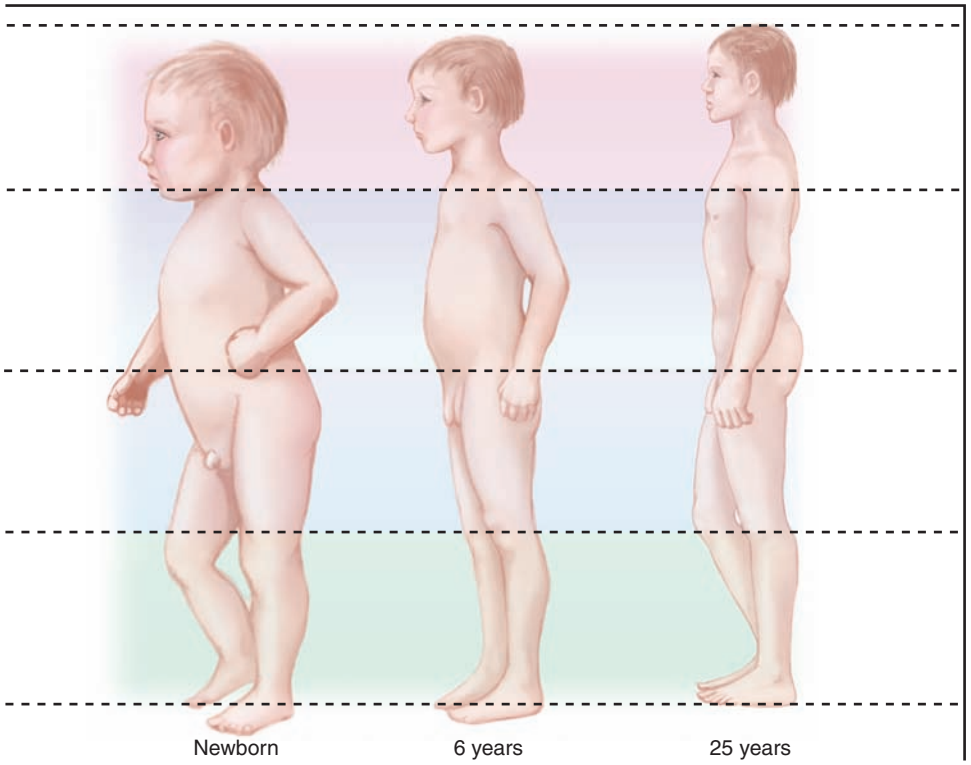

FIGURE 37.1 Proportion of head to body height in the newborn, child, and adult.

Remember Antonio, the 3-month-old with lethargy, a weak cry, and vomiting? What additional health history and physical examination assessment information should the nurse obtain?

Assessment

Assessment of neurologic dysfunction in children includes health history, physical examination, and laboratory and diagnostic testing.

▶ *Take* NOTE!

Neurologic assessment should proceed from least invasive to most invasive. The use of toys and familiar objects, as well as incorporating play, will help promote cooperation from the child.

Health History

The health history consists of past medical history, including the mother's pregnancy history, family history, and history of present illness (when the symptoms started and how they have progressed) as well as treatments used at home. The past medical history might be significant for prematurity, difficult birth, infection during pregnancy, nausea, vomiting, headaches, changes in gait, falls, visual disturbances, or recent trauma. Family history might be significant for genetic disorders with neurologic manifestations; seizure disorders; or headaches. When eliciting the history of the present illness, inquire about the following:

- Nausea
- Vomiting
- Changes in gait
- Visual disturbances
- Complaints of headaches
- Recent trauma
- Changes in cognition
- Change in consciousness, including any loss of consciousness
- Poor feeding
- Lethargy
- Increased irritability
- Fever
- Neck pain
- Altered muscle tonicity
- Delays in growth and development
- Ingestion or inhalation of neurotoxic substances or chemicals

Physical Examination

Physical examination of the nervous system consists of inspection and observation; palpation; and auscultation.

COMMON MEDICAL TREATMENTS 37.1

Treatment	Explanation	Indications	Nursing Implications
Shunt placement	A catheter is placed in the ventricle to pass the CSF to the peritoneal cavity, atrium of the heart, or pleural spaces. (Ventriculoperitoneal shunts are commonly used.)	Hydrocephalus, increased ICP	Monitor: • For signs and symptoms of increased ICP • Neurologic status closely • Level of consciousness and vital signs • For signs and symptoms of infection
Ventilation	Hyperventilation to decrease $PaCO_2$, which will result in vasoconstriction and therefore decrease ICP Adequate oxygenation to prevent hypoxia and further damage to the brain	Increased ICP	Monitor: • Arterial blood gases • For signs and symptoms of increased ICP • Pulse oximetry
PT/OT/ST	Therapies are used to improve motor function and ability of clients with neurologic disorders.	Head injury, mental retardation	Ensure adequate communication exists within the interdisciplinary team.
External ventricular drainage (EVD)	A catheter is temporarily placed in the ventricle and CSF is drained in a closed system to an external reservoir	Most commonly used with shunt infections until CSF is sterile and shunt can be replaced; treats acute-onset hydrocephalus, meningitis, encephalitis, tumors that cause blockage of CSF, closed head injury, subarachnoid hemorrhage, increased ICP; also can be used to monitor ICP	Monitor: • For signs and symptoms of increased ICP • Neurologic status closely • Level of consciousness and vital signs • For signs and symptoms of infection • Level of collection container when drain is unclamped
Ventricular tap	To reduce accumulation of CSF and decrease ICP	Increased ICP	Monitor: • Level of consciousness • Neurologic status
Vagal nerve stimulator	A nerve stimulator is implanted and a lead wire running under the skin is wrapped around the vagus nerve. The stimulator is programmed to provide the appropriate dose of stimulation at preset intervals; additional stimulation can be administered.	Short- and long-term seizure management in children >12 years of age	Monitor: • For signs and symptoms of infection • For seizure activity
Ketogenic diet	Diet involving high intake of fats, adequate protein, and a very low intake of carbohydrates, resulting in a ketosis state. Child is kept in a mild state of dehydration.	Prevention, control, and reduction of seizures, in particular for children with difficult-to-control seizures	Monitor: • Input and output closely • For seizure activity • Growth and nutritional status The diet is time consuming and many clients find it unpalatable; therefore all families and clients do not accept it.

DRUG GUIDE 37.1

Medication	Action/Indication	Nursing Implications
Antibiotics (oral, parenteral, intrathecal)	Treatment of bacterial meningitis and shunt infections/kill and prevent the growth of bacteria	Check for antibiotic allergies. Monitor serum levels to ensure therapeutic dosing if indicated. Give as prescribed for the length of time prescribed.
Anticonvulsants (oral, parenteral)	Decrease hyperexcitability of nerves Treatment and prevention of seizures	Maintain seizure precautions. Monitor for drug interactions and long-term adverse effects. Monitor and document all seizure activity. Many are used in combination, but need to be aware of interactions and long-term adverse effects. Stopping drug abruptly may precipitate seizures or even status epilepticus.
Benzodiazepines Diazepam (oral, rectal, or parenteral) Lorazepam (parenteral or oral)	Minor sedative that prevents or stops seizures by slowing down the CNS, making abnormal electrical activity unlikely. Treatment for status epilepticus	Diazepam is available in rectal form to stop prolonged seizures in children. Useful for home management; nurses must educate family members on administration and when to call MD. Monitor sedation level and for cessation of seizure activity.
Analgesics (acetaminophen, ibuprofen,ketorolac, morphine)	Blocks pain impulse in response to inhibition of prostaglandin synthesis. Narcotic analgesics (i.e., morphine) act on receptors in the brain to alter perception of pain. Used to treat pain. Used to help avoid increase in ICP.	Monitor for improvements in pain. Monitor sedation and respiratory status with narcotics. Monitor neurologic status closely. Used cautiously because loss of accurate neurologic evaluation can occur
Osmotic diuretics (i.e., mannitol)	Increases plasma osmolality, therefore inducing diffusion back into plasma and extravascular space/reduces ICP	Monitor electrolytes. Monitor I/O closely. Monitor vital signs. Monitor for signs and symptoms of increased ICP.
Corticosteroids (i.e., dexamethasone)	Suppresses inflammation and normal immune response/ reduces cerebral edema	Give oral doses with food. Dosage must be tapered before discontinuing.

Inspection and Observation

Specific areas to inspect and observe include level of consciousness (LOC); vital signs; head, face, and neck; cranial nerve function; motor function; reflexes; sensory function; and **increased intracranial pressure (ICP)**.

Level of Consciousness (LOC). Begin the physical examination with inspection and observation. Observe the child's LOC, noting a decrease or significant changes. LOC is the earliest indicator of improvement or deterioration of neurologic status. Extreme irritability or lethargy is considered an abnormal finding. Consciousness consists of alertness, which is a wakeful state and includes the ability to respond to stimuli; and cognition, which includes the ability to process stimuli and demonstrate a verbal or motor response. Five different states constitute the levels of consciousness:

1. *Full consciousness* is defined as a state in which the child is awake and alert; is oriented to time, place, and person; and exhibits age-appropriate behaviors.
2. *Confusion* is defined as a state in which disorientation exists. The child may be alert but responds inappropriately to questions.
3. *Obtunded* is defined as a state in which the child has limited responses to the environment and falls asleep unless stimulation is provided.
4. *Stupor* exists when the child only responds to vigorous stimulation.
5. *Coma* defines a state in which the child cannot be aroused, even with painful stimuli.

The Pediatric Glasgow Coma Scale is a popular scale used to standardize degree of consciousness. It consists of three parts: eye opening, verbal response, and motor

NEUROLOGIC ASSESSMENT

Pupils	Right	Size	
		Reaction	
	Left	Size	
		Reaction	

++ = Brisk
\+ = Sluggish
– = No reaction
C = Eye closed by swelling

1 2 3 4 5 6 7 8

FIGURE 37.2 Pediatric Glasgow Coma Scale (GCS). The Pediatric GCS provides for developmentally appropriate cues to assess level of consciousness (LOC) in infants and children. Numeric values are assigned to the levels of response and the sum provides an overall picture, as well as an objective measure, of the child's LOC. The lower the score, the less responsive the child.

response (Fig. 37.2). When assessing LOC in children, consider that the infant or child may not respond to unfamiliar voices in an unfamiliar environment. Therefore it may be helpful to have a parent present to elicit the response.

▶ Take NOTE!

Parents many times will be the first to notice changes in their child's LOC. Listen to parents and respond to their concerns.

▶ Take NOTE!

Lack of response to painful stimuli is abnormal and can indicate a life-threatening condition. Report this finding immediately.

Vital Signs. Assessment of vital signs can provide probable underlying causes for altered LOC as well as reveal the adequacy of oxygenation and circulation. Certain neurologic conditions like cerebral infections, increased ICP, coma, brain stem injury, or head injuries can cause alterations in the pediatric client's vital signs.

Head, Face, and Neck. Inspect and observe the head for size and shape. Abnormal skull shape can result from premature closure or widening of sutures. Inspect and observe the face for symmetry. Asymmetry may occur due to paralysis of certain cranial nerves, position *in utero*, or swelling caused by trauma. Assess range of motion of the neck. Alterations in range of motion can indicate CNS infections such as meningitis.

The most dramatic increase in brain volume occurs during the last 3 months of fetal development and the first 2 years of life. The relationship between head and brain growth explains why head circumference is a standard assessment made in children less than 3 years of age. All children less than 3 years old, and any child whose head size is questionable, should have their head circumference measured and plotted on a growth chart (see Appendix F for growth charts). Assessment of the growth trend of the head is important in detecting potential neurologic conditions. Report and investigate any variation in head circumference percentiles over time because variations may indicate abnormal brain or skull growth. A smaller than normal **head circumference** may indicate microcephaly, and a larger than normal head circumference may indicate hydrocephalus.

▶ Take NOTE!

Any assessment that involves movement of the head and neck should not be attempted in cases of trauma or suspected trauma until cervical injury is ruled out. Maintain complete immobilization of the cervical spine until that time.

Cranial Nerve Function. Techniques of assessment of cranial nerve function are similar to techniques for adult assessment. The method of obtaining responses may vary based on age and developmental level of the child. Certain elements of the adult assessment may be omitted. Alter-

TABLE 37.1 Assessment of Cranial Nerves in Infants and Children

Cranial Nerve	Function	Assessment Procedure
I (Olfactory)	Sense of smell	Not evaluated in infants and young children. In children, assess child's ability to recognize common smells (i.e., an orange) while eyes are closed.
II (Optic), III (Oculomotor), IV (Trochlear), VI (Abducens)	Vision, motor control and sensation of eye muscles, movement of major eye muscles	Assess oculomotor ability by having child follow object (toy or brightly colored object). Assess vision fields and visual acuity in older child. Assess pupil reaction same as adult. May need to talk to child or have parent in visual field while applying light stimulus
V (Trigeminal)	Mastication muscles and facial sensation	Note strength of infant's suck on pacifier, examiner's thumb, or bottle. In children, assess strength of bite and ability to discern light touch on face.
VII (Facial)	Facial muscles, salivation, and taste	Note symmetry of facial expressions; in infant, monitor during spontaneous cries or smiles. In older child, test as in adults. Assess taste by asking to discern certain common tastes (salt, sugar).
VIII (Acoustic)	Hearing	In infant, note response, to voice. In children, use whisper test or Weber or Rinne test.
IX (Glossopharyngeal), X (Vagus)	Motor impulses to heart and other organs, swallowing, and gag reflex	Gag reflex and swallowing tested as in adults. Check time of last feeding, especially in the infant, to avoid vomiting when gag reflex is tested.
XI (Accessory)	Impulses to muscles of shoulders and pharynx	In infants, note symmetry of head position when placed in the sitting position. In children, same as adults
XII (Hypoglossal)	Motor impulses to tongue and skeletal muscles	In infants, note spontaneous tongue movements. In children, same as adults

ations in cranial nerve function can be the result of compression of a specific nerve, infection, or trauma leading to brain injury. Refer to Table 37.1 for an explanation of cranial nerve assessment in children.

Use the doll's eyes maneuver to evaluate cranial nerves III, IV, and VI. This maneuver can be helpful when assessing an infant, uncooperative child, or comatose client. It examines horizontal and vertical eye movements by turning the head in one direction and assessing if the eyes move symmetrically in the other direction. For example, if you suddenly turn the child's head to the right, the child's eyes should look to the left symmetrically. Assess vertical eye movements in a similar manner by flexing or extending the neck. Absence of expected eye movements may indicate increased ICP.

When assessing oculomotor function, be sure to note nystagmus or sunset appearance of the eyes. Observe for nystagmus by looking for involuntary, rapid, rhythmic eye movements that may be present at rest or with eye movement. Horizontal nystagmus may occur with lesions in the brainstem and can be the result of certain medications (phenytoin in particular). Vertical nystagmus indicates brainstem dysfunction. *Sunsetting* is when the sclera of the eyes is showing over the top of the iris (Fig. 37.3). Sunset eyes may indicate increased ICP as seen in hydrocephalus. Pupillary response is often abnormal when a neurologic disorder is present. Refer to Figure 37.4 for illustrations of varied pupillary responses.

▶ **Take** NOTE!

Report immediately the sudden presence of fixed and dilated pupils

Motor Function. Alterations in motor function, like changes in gait, muscle tone, or strength, may indicate certain neurologic problems such as increased ICP, head

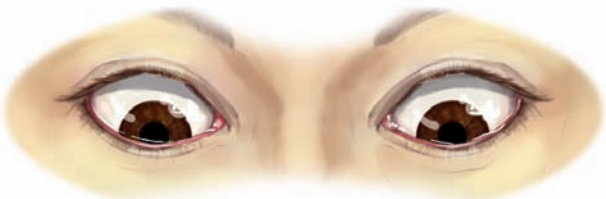

FIGURE 37.3 Sunsetting of the eyes is a sign of increased intracranial pressure.

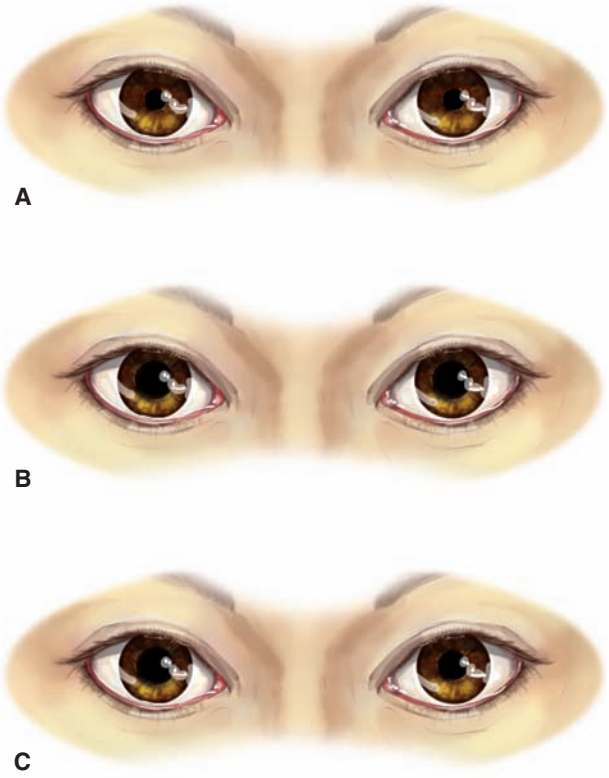

FIGURE 37.4 Assessing pupil size and reaction: (**A**) *Pinpoint* is commonly observed in poisonings, brainstem dysfunction, and opiate use. (**B**) *Dilated but reactive* is seen after seizures. *Fixed and dilated* is associated with brainstem herniation secondary to increased intracranial pressure. (**C**) *One dilated but reactive* is associated with intracranial mass.

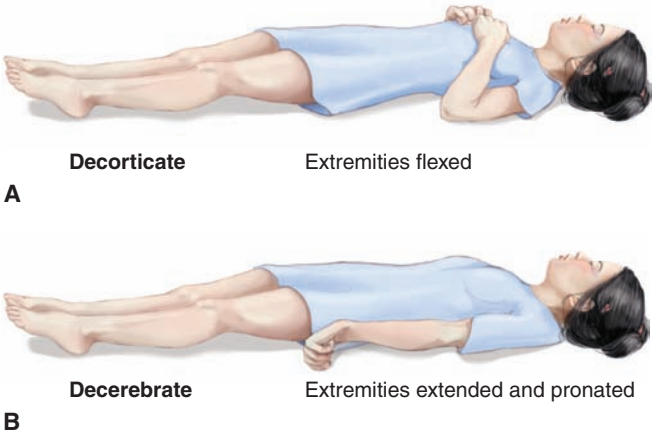

FIGURE 37.5 (**A**) Decorticate posturing occurs with damage of the cerebral cortex and includes adduction of the arms, flexion at the elbows with arms held over chest, and flexion of the wrists with hands fisted. Lower extremities are adducted and extended. (**B**) Decerebrate posturing occurs with damage to the midbrain and includes extension and pronation of the arms and legs.

injury, and cerebral infections. Observe muscle strength, size, and tone in the infant or child. Assess bilaterally and compare. Observe spontaneous activity, posture, and balance and assess for asymmetrical movements. In the infant, observe resting posture, which will normally be a slightly flexed posture. The infant should be able to extend extremities to a normal stretch. Because cortical control of motor function is lost in certain neurologic disorders, postural reflexes reemerge and are directly related to the area of the brain that is damaged. Therefore, it is important to assess for two distinct types of posturing that may occur. **Decorticate posturing** occurs with damage of the cerebral cortex (Fig. 37.5A). **Decerebrate posturing** occurs with damage at the level of the brainstem (Fig. 37.5B). Both types of posturing are characterized by extremely rigid muscle tone.

Reflexes. Testing of deep-tendon reflexes is part of the neurologic assessment, just as it is in adults. Testing of primitive and protective reflexes in the infant is important because infants cannot perform tasks on command. The Moro, tonic neck, and withdrawal reflexes are important in assessing neurologic health in infants. Refer to Chapter 25 for a further explanation of primitive and protective reflexes in infants (see Chapter 25, Table 25.2). Absence of certain reflexes, persistence of primitive reflexes after age of normal disappearance, or increases in reflexes may be present in specific neurologic conditions.

Sensory Function. When assessing sensory function, the child should be able to distinguish between light touch, pain, vibration, heat, and cold. When assessing an infant, limit the examination to responses to touch or pain. The normal response in a 4-month-old infant will be movement away from the stimulus. In the child, techniques similar to those used in the adult assessment are followed. Make sure to explain what you are doing to the child, especially before the pin-prick test, to gain continued cooperation. Alterations in sensory function can result from brain or spinal cord lesions.

Increased Intracranial Pressure. Increased ICP is a sign that may occur with many neurologic disorders. It may result from head trauma, birth trauma, hydrocephalus, infection, and brain tumors. Observe for signs and symptoms associated with increased ICP while caring for a child with a potential or suspected neurologic disorder. Refer to Comparison Chart 37.1 for early versus late signs and symptoms of increased ICP. As ICP increases, LOC decreases and the signs and symptoms will become more pronounced. It is essential to recognize early signs and symptoms of increased ICP and intervene immediately to prevent long-term damage and possible death.

Palpation

Palpation of the newborn and infant skull and fontanels is an important function of the neurologic examination.

COMPARISON CHART 37.1 Early vs. Late Signs of Increased Intracranial Pressure

Early Signs	Late Signs
• Headache	• Lowered level of consciousness
• Vomiting, possibly projectile	• Decreased motor and sensory responses
• Blurred vision, double vision (diplopia)	• Bradycardia
• Dizziness	• Irregular respirations
• Decreased pulse and respirations	• Cheyne-Stokes respirations
• Increased blood pressure or pulse pressure	• Decerebrate or decorticate posturing
• Pupil reaction time decreased and unequal	• Fixed and dilated pupils
• Sunset eyes	
• Changes in level of consciousness, irritability	
• Seizure activity	
• In infant will also see:	
• Bulging, tense fontanel	
• Wide sutures and increased head circumference	
• Dilated scalp veins	
• High-pitched cry	

Changes in size or fullness of the fontanels may exist in certain neurologic conditions and must be noted. A bulging fontanel can be a sign of increased ICP and is seen in such neurologic disorders as hydrocephalus and head traumas. It is normal for the fontanels to be full or bulging during crying; take this into consideration during assessment.

Note any premature closure of fontanels, which can indicate skull deformities such as craniosynostosis. The posterior fontanel normally closes by 2 months of age and the anterior fontanel normally closes by 12 to 18 months of age. In children with hydrocephalus, widening of the fontanels may be noted, along with a tense appearance and a resulting increase in head circumference.

Auscultation

Advanced practitioners may perform auscultation of the skull. Soft, symmetric bruits may be found in children less than 4 years of age or in children with acute febrile illness. A finding of a loud or localized bruit is usually significant and requires immediate further investigation. Increased ICP, resulting from conditions such as hydrocephalus, tumor, or meningitis, frequently produces intracranial bruits. Arterial venous malformations may also produce large bruits.

Laboratory and Diagnostic Testing

Common Laboratory and Diagnostic Tests 37.1 offers an explanation of the most commonly used laboratory and diagnostic tests utilized when considering neurologic disorders. The tests can assist the physician in diagnosing the disorder and/or serve as guidelines in determining ongoing treatment. Laboratory or nonnursing personnel obtain some of the tests, while the nurse might obtain others. In either instance, the nurse should be familiar with how the tests are obtained, what they are used for, and normal versus abnormal results. This knowledge will also be necessary when providing client and family education related to the testing. Many of these tests, such as **lumbar puncture** (LP; see Fig. 37.6), can be frightening to parents and the child. Prepare the family and the child and provide support and reassurance during and after the test or procedure.

After completing an assessment of Antonio, the nurse noted the following: a full anterior fontanel; when being held, Antonio was inconsolable; when lying still, he was calmer and in the opisthotonic position.

Nursing Diagnoses and Related Interventions

Upon completion of a thorough assessment, the nurse might identify several nursing diagnoses, including:

- Decreased intracranial adaptive capacity
- Ineffective tissue perfusion: cerebral
- Risk for injury
- Disturbed sensory perception
- Risk for infection
- Pain
- Self-care deficit
- Impaired physical mobility

(text continues on page 1150)

COMMON LABORATORY AND DIAGNOSTIC TESTS 37.1

Test	Explanation	Indications	Nursing Implications
Lumbar puncture (LP)	Withdrawal of CSF from the subarachnoid space for analysis	To diagnose hemorrhage, infection or obstruction Can obtain measurement of spinal fluid pressure	Assist with proper positioning (see Fig. 37.6). Help child maintain position and remain still. Maintain strict asepsis. Assist with collection and transport of specimen. Encourage fluids after procedure if not contraindicated. Keep child flat for 1 hour if ordered. Apply EMLA cream to puncture site 30–60 min before procedure to reduce pain, if ordered.
Head and neck x-ray	Radiographic image of the head and neck will show skull and spine structures	Detects skull and spinal fractures; shows location and course of ventricular catheters; reveals information about increased intracranial pressure (ICP) and skull defects	Children may be afraid. Allow a parent or family member to accompany the child. If the child is unable or unwilling to stay still for the x-ray, restraint may be necessary. The time of restraint should be limited to the amount of time needed for the x-ray.
Fluoroscopy	Radiographic examination that uses continuous x-rays to show live up-to-date images	Can assess cervical spine for instability during movement	Same as head and neck x-rays. Child will need to cooperate with flexion and extension of neck.
Cerebral angiography	X-ray study of cerebral blood vessels. Involves injection of a contrast medium and use of fluoroscopy	Can assess for vessel defects or space-occupying lesions	Same as head and neck x-rays. Assess for allergy to contrast medium. Push fluids following procedure, if not contraindicated, to help flush out contrast medium.
Ultrasound	Use of sound waves to locate the depth and structure within soft tissues and fluid	Used to assess intracranial hemorrhage in newborns, and ventricular size	Better tolerated by nonsedated children than CT or MRI Can be performed portably at bedside
Computed tomography (CT)	Noninvasive x-ray study that looks at tissue density and structures. Images a "slice" of client's tissue	To diagnose congenital abnormalities, such as neural tube defects, hemorrhage, tumors, fractures	Machine is large and can be frightening to children. Procedure can be lengthy and child must remain still. If unable to do so, sedation may be necessary. Can be performed with or without use of contrast medium; if used, assess for allergy. Encourage fluids postprocedure if not contraindicated.

(continued)

COMMON LABORATORY AND DIAGNOSTIC TESTS 37.1 (continued)

Test	Explanation	Indications	Nursing Implications
Electroencephalogram (EEG)	Measure electrical activity of the brain	To diagnose seizures and brain death	Must remain still. If unable to do so, sedation may be necessary but should be avoided if possible because sedatives can alter the EEG reading. Inform technician of what anticonvulsants the client's taking. Morning anticonvulsants may need to be held.
Magnetic resonance imaging (MRI)	Use of magnetic field to show different tissue compositions	Used to assess tumors and inflammation; used to diagnose congenital abnormalities, such as neural tube defects; shows normal versus abnormal brain tissue	Client may not have any metal devices, internal or external, while undergoing MRI (ensure hospital gown does not have metal snaps). Procedure can be lengthy and child must remain still. Child is placed in long narrow tube and the machine makes a booming noise when it is turned on and off during the procedure; therefore can be difficult to gain cooperation. If the child is unable to remain still, sedation may be necessary. Can be performed with or without use of a contrast medium. If contrast medium is used, assess for allergy. Encourage fluids postprocedure if not contraindicated.
Positron emission tomography (PET)	Similar to CT or MRI but radioisotope is added. Measures physiologic function	Provides information on brain functional development. Can assist in identifying seizure foci. Can assess tumors and brain metabolism.	Procedure can be lengthy and child must remain still. If unable to do so, sedation may be necessary. IV access will be needed for the procedure. Encourage fluids postprocedure if not contraindicated, to help body eliminate radioisotopes.
Intracranial pressure (ICP) monitoring (intraventricular catheter, subarachnoid screw or bolt, epidural sensor, anterior fontanel pressure monitor)	A sensing device is placed in the head that monitors the pressure intracranially.	Used to monitor ICP resulting from hydrocephalus, acute head trauma, and brain tumors. Ventricular catheter also allows for draining of CSF to help reduce ICP.	Usually monitored in critical care setting. Monitor for signs and symptoms of increased ICP. Monitor for infection. Keep head of bed elevated 15–30 degrees. Alarms for monitoring device should remain on at all times. Reduce stimulation and avoid interventions that may cause pain or stress and result in an increased ICP.

Test	Explanation	Indications	Nursing Implications
Video electro-encephalogram (EEG)	Measure electrical activity of the brain continuously along with recorded video of actions and behaviors	Can help determine precise localization of seizure area before surgery. Assists in diagnosis and management of seizures by correlating behaviors with abnormal EEG activity	Ensure that seizure precautions are in place. Parent or caregiver must be with client at all times. Client movements are limited and usually confined to the room. When client changes position, ensure that he or she is still seen by video camera. Boredom can be a problem. Must notify nurse if seizure activity occurs; push the alert button to highlight attack on EEG recoding. Nurse must immediately go to the room, expose as much of the client as possible (remove covers; if at night, turn on light), and avoid blocking the camera. Ask questions (i.e., what is your name, can you raise your left arm, remember the word banana) to help assess responsiveness more accurately. Stay with the client until full recovery has occurred. Ask the client what word you asked them to remember, and document all findings and time of the event.

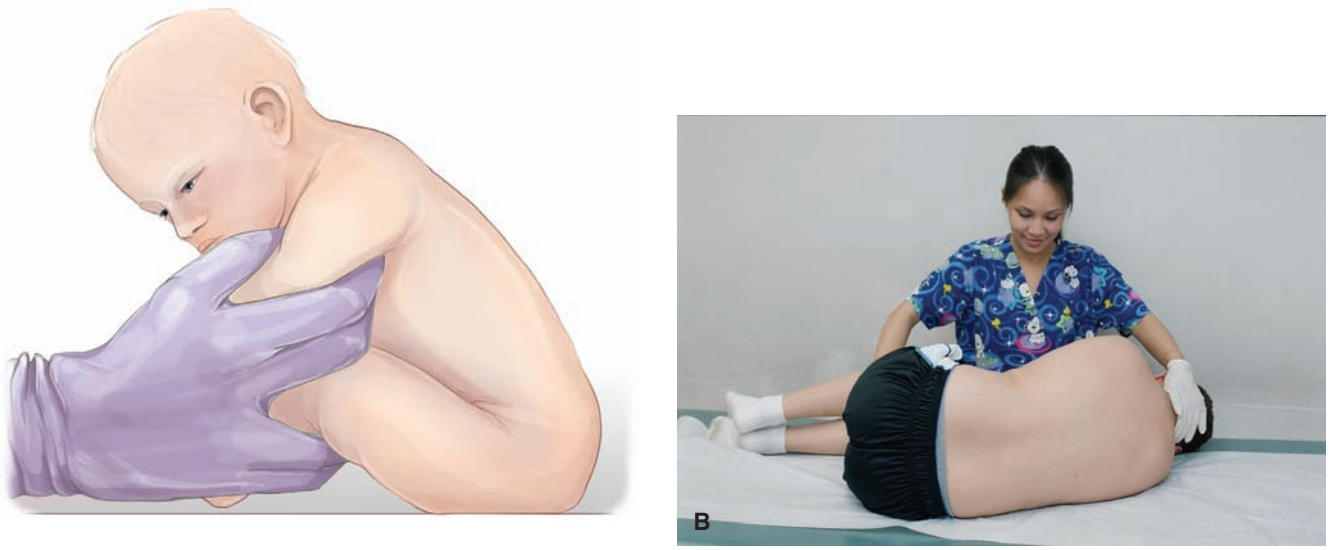

FIGURE 37.6 Proper positioning for a lumbar puncture. (**A**) The newborn is positioned upright with head flexed forward. (**B**) Child or older infant is positioned on the side with head flexed forward and knees flexed to abdomen.

- Risk for delayed development
- Imbalanced nutrition: less than body requirements
- Risk for deficient fluid volume
- Deficient knowledge
- Interrupted family processes

Nursing goals, interventions, and evaluation for the child with a neurologic disorder are based on the nursing diagnoses.

Based on the assessment findings, what would be your top three prioritized nursing diagnoses for Antonio?

Nursing Care Plan 37.1 may be used as a guide in planning nursing care for the child with a neurologic disorder. It should be individualized based on the client's symptoms and needs. Additional information will be included later in this chapter related to specific disorders.

Based on your top three nursing diagnoses for Antonio, describe appropriate nursing interventions.

Seizure Disorders

Seizures occur in approximately 10% of children (Behrman, Kliegman, & Jenson, 2004). Most seizures are caused by disorders that originate outside of the brain such as a high fever, infection, head trauma, hypoxia, toxins, or cardiac arrhythmias. Less than one third of seizures in children are caused by epilepsy (Behrman et al., 2004). Seizure disorders discussed below include epilepsy, febrile seizures, and neonatal seizures.

EPILEPSY

Epilepsy is a condition in which seizures are triggered recurrently from within the brain. Epilepsy is a common neurologic disorder discovered in childhood, although brain injury or infection can cause epilepsy at any age. Epilepsy is considered present when two or more unprovoked seizures occur more than 24 hours apart. The prognosis for most children with seizures associated with epilepsy is good. Many children will outgrow epilepsy, but some children will have persistent seizures that are difficult to manage and may be unresponsive to pharmacologic interventions. Living with a seizure disorder may have a devastating impact on the quality of life of the child and family.

Pathophysiology

Epilepsy is a complex disorder of the CNS in which brain function is affected. Recurrent or unprovoked seizures are the clinical manifestation of epilepsy and result from a disruption of electrical communication among the neurons of the brain. This disruption results from an imbalance between the excitatory and inhibitory mechanisms in the brain, causing the neurons to either fire when they are not supposed to or not fire when they should. Epilepsy may be acquired and related to brain injury or it may be a familial tendency, but in most cases the cause is unknown.

There are two major categories of seizures: partial and generalized seizures. In partial seizures only one area of the brain is involved, while general seizures involve the entire brain. Partial seizures account for a large portion of childhood seizures and are classified as *simple* or *complex*. Generalized seizures include infantile spasms, absence seizures, tonic-clonic seizures, myoclonic seizures, and atonic seizures. There are many different types of seizures, and the classification of the type of seizure is crucial in assisting with the management and control of seizures. Not all cases are easily classified. The most common seizure types are discussed in Table 37.2.

Therapeutic Management

Management of epilepsy focuses on controlling seizures or reducing their frequency, along with helping the child who has recurrent seizures and his or her family to learn to live with the seizures. The primary mode of treatment is the use of anticonvulsants. There have been significant advances in the treatment of epilepsy due to the many new anticonvulsant medications that have become available in recent years (Table 37.3). Most anticonvulsants are taken orally and are often used in combination. Different medications control different types of seizures, which may be due to individual variation. It can take time to find the right combination to best control an individual's seizures.

If seizures remain uncontrolled, another option for managing them is surgery. Depending on the area of the brain that is affected, it may be possible to remove the area that is responsible for the seizure activity or to interrupt the impulses from spreading and therefore stop or reduce the seizures. The adverse effects range from mild to severe, depending on the area of the brain that is affected. Other nonpharmacologic treatments that may be considered in children with intractable seizures include a ketogenic diet or placement of a vagal nerve stimulator. Refer to Common Medical Treatments 37.1.

Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1140. Assessment findings pertinent to epilepsy are discussed below.

Health History

Elicit a description of the present illness and chief complaint, which will usually involve a seizure episode. Gain information to help characterize the episode as a seizure

(text continues on page 1155)

Nursing Care Plan 37.1

OVERVIEW FOR THE CHILD WITH A NEUROLOGIC DISORDER

NURSING DIAGNOSIS: Decreased intracranial adaptive capacity related to compression of brain tissue due to increased CSF or cerebral edema secondary to increased ICP resulting from brain injury, congenital structural defects, brain tumor, decreased reabsorption of CSF, or shunt malfunction as evidenced by vomiting, headache, complaints of visual disturbances, decreased pulse and respirations, elevated blood pressure or pulse pressure, changes in level of consciousness, increased head circumference, or bulging fontanel

Outcome Identification and Evaluation

Child will remain free of signs and symptoms of increased intracranial pressure as evidenced by *remaining free of headache, vomiting, vision disturbances, vital signs within parameters for age, no signs of altered levels of consciousness, free of excessive irritability or lethargy, head circumference is within parameters for age.*

Interventions: Promoting Adequate Intracranial Adaptive Capacity

- Assess neurologic status closely, monitor for signs and symptoms of increased ICP: *changes in level of consciousness, signs of irritability or lethargy, changes in pupillary reaction can indicate changes in ICP.*
- Monitor vital signs: *decreased pulse and respiratory rate and increased blood pressure or pulse pressure can indicate increased ICP.*
- Measure head circumference in children <3 years of age: *increases in head circumference outside parameters for age can indicate increased ICP.*
- Elevate head of bed 15–30 degrees to *facilitate venous return and can help to reduce ICP.*
- Minimize environmental stimuli and noise, avoid pain-producing procedures if possible: *all can increase ICP.*
- Have emergency equipment ready and available: *increased ICP can result in respiratory or cardiac failure.*
- Notify MD immediately if changes in assessment are noted: *early intervention is critical to prevent neurologic damage and death.*

NURSING DIAGNOSIS: Risk for ineffective (cerebral) tissue perfusion related to increased ICP, alteration in blood flow secondary to hemorrhage, vessel malformation, cerebral edema

Outcome Identification and Evaluation

Child will exhibit adequate cerebral tissue perfusion through course of illness and childhood: *Child will remain alert and oriented with no signs of altered level of consciousness; vital signs will be within parameters for age; motor, sensory, and cognitive function will be within parameters for age; head circumference remains within parameters for age.*

Interventions: Promoting Adequate Tissue Perfusion

- Assess neurologic status closely, monitor for signs and symptoms of increased ICP: *changes in level of consciousness, signs of irritability or lethargy, changes in pupillary reaction can indicate decreased cerebral tissue perfusion.*
- Monitor vital signs: *decreased pulse and respiratory rate and increased blood pressure or pulse pressure can indicate increased ICP, which can lead to decreased cerebral perfusion.*
- Have emergency equipment ready and available: *decreased cerebral perfusion can result in respiratory or cardiac failure.*
- Notify MD immediately if changes in assessment are noted: e*arly intervention is critical to prevent neurologic damage and death.*

(continued)

Nursing Care Plan 37.1 (continued)

NURSING DIAGNOSIS: Risk for injury related to altered level of consciousness, weakness, dizziness, ataxia, loss of muscle coordination secondary to seizure activity

Outcome Identification and Evaluation

Child will remain free of injury as evidenced by *no signs of aspiration or traumatic injury.*

Interventions: Preventing Injury

- Ensure child has patent airway and adequate oxygenation (have suction, oxygen available at bedside) and place child in side-lying position if possible: *a child with altered level of consciousness may not be able to manage his secretions and is at risk for aspiration and ineffective airway clearance; providing suction and oxygenation can help ensure an open airway and the side-lying position can help secretions drain and prevent obstruction of airway or aspiration.*
- Protect child from hurting self during seizures or changes in level of consciousness by removing environmental obstacles, easing child to lying position, and padding side rails: *helps to keep environment safe.*
- Institute seizure precautions for any child at risk for seizure activity (see Box 37.2): *to help prevent injury that can result from acute seizure activity.*
- With seizure activity do not insert a tongue blade or restrain child: *can lead to injury to caregiver and child.*
- Administer anticonvulsant medications as ordered: *will help to promote cessation and prevention of seizure activity.*
- Assist child with ambulation: *help prevent injury in child with weakness, dizziness, ataxia.*
- Allow for periods of rest: *to prevent fatigue and decrease risk of injury.*

NURSING DIAGNOSIS: Disturbed sensory perception related to presence of neurologic lesion or pressure on sensory or motor nerves secondary to increased ICP, presence of tumor, swelling postoperatively as evidenced by visual disturbances (i.e., reports of double vision), pupillary changes, nystagmus, ataxia, balance disturbances, or loss of response to stimuli

Outcome Identification and Evaluation

Child will be free of changes in sensory perception or will remain at baseline as evidenced by *no complaints of double vision, PERRLA, no disturbances of gait or balance noted, and no increased in loss of responses to stimuli.*

Interventions: Managing Disturbed Sensory Perception

- Assess for changes in sensory perception: *provides baseline data and allows nurse to recognize change in sensory perception early.*
- Monitor child for risk of injury secondary to changes in sensory perception: *visual changes, disturbances of gait or balance increase child's risk for injury.*
- Notify MD of changes in sensory perception: *can indicate increased ICP and medical emergency.*
- Assist child to learn to use adaptive methods to live with permanent changes in sensory perception (i.e., use of eyeglasses) and maximize the use of intact senses: *adaptive devices can enhance sensory input and intact senses can often compensate for impaired senses.*
- Provide familiar sounds (voices, music): *can help relieve anxiety related to changes in sensory perception, especially visual changes.*

Nursing Care Plan 37.1 (continued)

NURSING DIAGNOSIS: Risk for infection related to surgical interventions, presence of foreign body (i.e., shunt), trauma to skull, nutritional deficiencies, stasis of pulmonary secretions and urine, presence of infectious organisms as evidenced by fever, poor feeding, decreased responsiveness and presence of virus or bacteria on laboratory screening

Outcome Identification and Evaluation

Child will exhibit no signs or symptoms of local or systemic infection and will not spread infection to others: *Symptoms of infection will decrease over time; others will remain free of infection.*

Interventions: Preventing Infection

- Monitor vital signs: *elevation in temperature can indicate presence of infection.*
- Monitor incision sites for signs of local infection: *redness, warmth, drainage, swelling, pain at incision site can indicate presence of infection.*
- Maintain aseptic technique—practice good hand washing, use proper technique when managing postoperative incisions and external shunts: *to prevent introduction of further infectious agents.*
- Administer antibiotics as prescribed: *to prevent or treat bacterial infection.*
- Encourage nutritious diet and proper hydration according to child's preferences and ability to feed orally: *to assist body's natural defenses against infection.*
- Isolation of child as required: *to prevent nosocomial spread of infection.*
- Teach child and family preventive measures such as good hand washing, covering mouth and nose upon cough or sneeze, adequate disposal of used tissues: *to prevent nosocomial or community spread of infection.*

NURSING DIAGNOSIS: Self-care deficit related to neuromuscular impairments; cognitive deficits as evidenced by an inability to perform hygiene care and transfer self independently

Outcome Identification and Evaluation

Child will demonstrate ability to care for self within age parameters and limits of disease: *Child is able to feed, dress, manage elimination within limits of disease and age.*

Interventions: Maximizing Self-Care

- Introduce child and family to self-help methods as soon as possible: *promotes independence from the beginning.*
- Encourage family and staff to allow child to do as much as possible: *allows child to gain confidence and independence.*
- Teach specific measures for bowel and urinary elimination as needed: *promotes independence, increases self-care abilities and self-esteem.*
- Collaborate with physical therapy, occupational therapy, and speech therapy departments to provide child and family with appropriate tools to modify environment and methods to promote transferring and self-care: *allows for maximum functioning.*
- Praise accomplishments and emphasize child's abilities: *helps improve self-esteem and encourages feeling of confidence and competence.*
- Balance activity with periods to rest: *to reduce fatigue and increase energy for self-care.*

NURSING DIAGNOSIS: Impaired physical mobility related to muscle weakness, hypertonicity, impaired coordination, loss of muscle function or control as evidenced by an inability to move extremities, to ambulate without assistance, to move without limitations

Outcome Identification and Evaluation

Child will be able to engage in activities within age parameters and limits of disease: *Child is able to move extremities, move about environment, and participate in exercise programs within limits of age and disease.*

Interventions: Maximizing Physical Mobility

- Encourage gross and fine motor activities: *facilitates motor development.*
- Collaborate with physical therapy, occupational therapy, and speech therapy departments to strengthen muscles and promote optimal mobility: *facilitates motor development.*
- Utilize passive and active ROM and teach child and family how to perform: *prevent contractures, facilitate joint mobility and muscle development (active ROM) to help increase mobility.*
- Praise accomplishments and emphasize child's abilities: *helps improve self-esteem and encourages feeling of confidence and competence.*

(continued)

Nursing Care Plan 37.1 (continued)

NURSING DIAGNOSIS: Risk for delayed development related to physical disability, cognitive deficits, activity restrictions

Outcome Identification and Evaluation

Child will demonstrate developmental milestones within age parameters and limits of disease: *Child expresses interest in the environment and people around him or her, and interacts with environment age appropriately.*

Interventions: Maximizing Development

- Use therapeutic play and adaptive toys: *helps facilitate developmental functioning.*
- Provide stimulating environment when possible: *to maximize potential for growth and development.*
- Praise accomplishments and emphasize child's abilities: *helps improve self-esteem and encourages feeling of confidence and competence.*

NURSING DIAGNOSIS: Nutrition, imbalanced: less than body requirements related to vomiting and difficulty feeding secondary to increased ICP; difficulty sucking, swallowing, or chewing; surgical incision pain or difficulty assuming normal feeding position; inability to feed self as evidenced by decreased oral intake, impaired swallowing, weight loss

Outcome Identification and Evaluation

Child will exhibit signs of adequate nutrition as evidenced by: *Weight will remain within parameters for age, skin turgor will be good, I/O will be within normal limits, adequate calories will be ingested, vomiting will cease or decrease.*

Interventions: Promoting Adequate Nutrition

- Monitor height and weight: *insufficient intake will lead to impaired growth and weight gain.*
- Monitor hydration status (moist mucous membranes, elastic skin turgor, adequate urine output): *insufficient intake can lead to dehydration.*
- Use techniques to promote caloric and nutritional intake and teach family (i.e., positioning, modified utensils, soft or blended foods, allow extra time): *these techniques can facilitate intake.*
- Assess respiratory system frequently: *to assess for aspiration.*
- Monitor for nausea and vomiting and medicate if ordered: *to help reduce vomiting and increase intake.*
- Monitor for pain and medicate if ordered: *to help reduce pain related to surgical incisions and trauma, and increase intake.*
- Assist family to assume as normal a feeding position as possible: *to help increase oral intake.*

NURSING DIAGNOSIS: Fluid volume deficit, risk for, related to vomiting, altered level of consciousness, poor feeding or intake, insensible loss due to fever, failure of regulatory mechanisms (as in diabetes insipidus) as evidenced by dry oral mucosa, decreased skin turgor, sudden weight loss, hypotension, and tachycardia

Outcome Identification and Evaluation

Fluid volume will be maintained and balanced: *oral mucosa moist and pink, skin turgor elastic, urine output at least 1–2 cc/kg/hr.*

Interventions: Promoting Adequate Fluid Balance

- Administer IV fluids if ordered: *to maintain adequate hydration in children who are NPO or unable to tolerate oral intake.*
- When oral intake is allowed and tolerated, encourage PO fluids: *to promote intake and maintain hydration.*
- Strict intake and output monitoring: *can help identify fluid imbalance and also detect signs of abnormal pituitary secretions resulting in conditions like syndrome of inappropriate antidiuretic hormone secretion (SIADH) and diabetes insipidus (DI) (see Chapter 48 for further information).*
- Maintain minimum hydration and avoid overhydration in clients where cerebral edema is a concern: *fluid overload can contribute to cerebral edema.*
- Urine specific gravity, urine and serum electrolytes (especially serum sodium), blood urea nitrogen, creatinine and osmolality, and daily weights: *are reliable indicators of fluid status and can also detect signs of abnormal pituitary secretions resulting in conditions like SIADH and DI.*

Nursing Care Plan 37.1 (continued)

NURSING DIAGNOSIS: Knowledge deficit related to lack of information regarding complex medical condition, prognosis, and medical needs as evidenced by verbalization, questions, or actions demonstrating lack of understanding regarding child's condition or care

Outcome Identification and Evaluation

Child and family will verbalize accurate information and understanding about condition, prognosis, and medical needs: *Child and family demonstrate knowledge of condition and prognosis and medical needs including possible causes, contributing factors, and treatment measures.*

Interventions: Providing Client and Family Teaching

- Assess child's and family's willingness to learn: *child and family must be willing to learn for teaching to be effective.*
- Provide family with time to adjust to diagnosis: *will help facilitate adjustment and ability to learn and participate in child's care.*
- Repeat information: *allows family and child time to learn and understand.*
- Teach in short sessions: *many short sessions are found to be more helpful than one long session.*
- Gear teaching to a level of understanding of the child and also the family (depends on age of child, physical condition, memory): *to ensure understanding.*
- Provide reinforcement and rewards: *help facilitate the teaching–learning process.*
- Use multiple modes of learning involving many senses (provide written, verbal, demonstration, and videos) when possible: *child and family more likely to retain information when presented in different ways using many senses.*

NURSING DIAGNOSIS: Family processes, interrupted related to child's illness, hospitalization, diagnosis of chronic illness in child and potential long-term affects of illness as evidenced by family's presence in hospital, missed work, demonstration of inadequate coping

Outcome Identification and Evaluation

Family will maintain functional system of support and demonstrate adequate coping, adaptation of roles and functions, and decreased anxiety: *Parents are involved in child's care, ask appropriate questions, express fears and concerns, and are able to discuss child's care and condition calmly.*

Interventions: Promoting Adequate Family Processes

- Encourage parents and family members to verbalize concerns related to child's illness, diagnosis, and prognosis: *allows the nurse to identify concerns and areas where further education may be needed. Demonstrates family-centered care.*
- Explain therapies, procedures, child's behaviors, and plan of care to parents: *understanding the child's current status and plan of care helps decrease anxiety.*
- Encourage parental involvement in care: *allows parents to feel needed and valued with a sense of control over their child's health.*
- Identify support system for family and child: *helps nurse identify needs and resources available for coping.*
- Educate family and child on additional resources available: *to help them develop a wide base of support.*

or as a nonepileptic event (see Box 37.1 for a list of nonepileptic events). It is rare to actually observe the child having a seizure; therefore a complete, accurate, and detailed history from a reliable source is essential. *Questions should include:*

- Where did the event occur—while sleeping, eating, playing, or just after waking?
- Description of child's behavior during the event—what types of movements, progression, length, respiratory status, apnea?
- How did the child act after the event?
- Have the episodes been recurrent? If so, how frequent?
- Any precipitating factors such as a fever, fall, activity, anxiety, infection, or exposure to strong stimuli such as flashing lights or loud noises?

Explore the client's current and past medical history for risk factors such as:

- Family history of seizures or epilepsy
- Any complications during the prenatal, perinatal, or postnatal periods
- Changes in developmental status or delays in developmental milestones
- Any recent illness, fever, trauma, or toxin exposure

TABLE 37.2 Common Types of Seizures

Type	Description	Characteristics
Infantile spasms	Uncommon type of generalized seizure seen in an epilepsy syndrome of infancy and childhood Usually seen between 3–12 months of age and usually stops by 2–4 years of age	Presents as a sudden jerk followed by stiffening May see: • Head flexed, arms extended, and legs drawn up • Arms flung out, knees are pulled up, and the body bends forward (referred to as "jackknife seizures") • Cry may precede or follow Majority of infants have some brain disorder before seizures begin. The infant seems to stop developing and may lose skills that he or she has already attained after the onset of infantile spasms. Steroid therapy and anticonvulsants are common forms of treatment.
Absence (formerly *petit mal*)	Type of generalized seizure; occurs more frequently in girls than boys Uncommon before age 5	Sudden cessation of motor activity or speech with a blank facial expression or rhythmic twitching of the mouth or blinking of the eyelids Complex absence seizure consists of myoclonic movements of the face, fingers, or extremities and possible loss of body tone. Lasts less than 30 seconds Child may experience countless seizures in a day. Not associated with a post-ictal (after seizure) state May go unrecognized or mistaken for inattentiveness because of subtle change in child's behavior
Tonic-clonic (formerly *grand mal*)	Extremely common generalized seizures. Most dramatic seizure type	Associated with an aura Loss of consciousness occurs and may be preceded by a piercing cry. Presents with entire body experiencing tonic contractions followed by rhythmic clonic contractions alternating with relaxation of all muscle groups Cyanosis may be noted due to apnea. Saliva may collect in the mouth due to inability to swallow. Child may bite tongue. Loss of sphincter control, especially the bladder, is common. Postictal phase: child will be semicomatose or in a deep sleep for approximately 30 minutes to 2 hours; usually responds only to painful stimuli. Child will have no memory of the seizure; may complain of headache and feeling fatigue. Safety of the child is a primary concern. See Teaching Guideline 37.1.
Myoclonic	Type of generalized seizure that involves the motor cortex of the brain. May occur along with other seizure forms.	Sudden, brief, massive muscle jerks that may involve the whole body or one body part Child may or may not lose consciousness.
Atonic	Type of generalized seizure often referred to as "drop attacks." Seen in children with Lennox-Gastaut syndrome	Sudden loss of muscle tone. In children, may only be a sudden drop of the head. Child will regain consciousness within a few seconds to a minute. Can result in injury related to violent fall

Type	Description	Characteristics
Simple partial	Type of partial seizure that occurs in part of the brain. The symptoms seen will depend on which area of the brain is affected.	Motor activity characterized by clonic or tonic movements involving the face, neck, and extremities Can include sensory signs such as numbness, tingling, paresthesia, or pain Usually persists for 10–20 seconds Child remains conscious and may verbalize during the seizure. No post-ictal state
Complex partial	Common type of partial seizure. May begin with a simple partial seizure then progress	May or may not have a preceding aura Consciousness will be impaired. Automatisms and complex purposeful movements are common features in infants and children. Infants will present with behaviors such as lip smacking, chewing, swallowing, and excessive salivation; can be difficult to distinguish from normal infant behavior In older children, will see picking or pulling at bed sheets or clothing, rubbing objects, or running or walking in a nondirective and repetitive fashion These seizures can be difficult to control.
Status epilepticus	Common neurologic emergency in children. Can occur with any seizure activity. Febrile seizures are the most common type. In children with epilepsy, it commonly occurs early in the course of epilepsy. Can be life threatening.	Prolonged or clustered seizures where consciousness does not return between seizures. The age of the child, cause of the seizures, and duration of status epilepticus influence prognosis. Prompt medical intervention is essential to reduce morbidity and mortality. Treatment: • Basic life support—ABCs (airway, breathing, circulation) • Administration of anticonvulsants to cease seizures is crucial. Common medications include benzodiazepines such as lorazepam and diazepam, and fosphenytoin. (See Drug Guide 37.1 and Table 37.3) • Blood glucose levels and electrolytes along with evaluation of the underlying cause should be initiated.

Children known to have epilepsy are often admitted to the hospital for other health-related issues or complications and treatment of their seizure disorder. The health history should include questions related to:

- Age of onset of seizures
- Seizure control—what medications is the child taking and has he or she been able to take them; when was his or her last seizure?
- Description and classification of seizures—does the child lose consciousness; does the child become apneic?
- Precipitating factors that may contribute to onset of seizures
- Adverse effects related to anticonvulsant medications
- Compliance with medication regimen

Physical Examination

Perform a complete neurologic examination. Careful assessment of the child's mental status, language, learning, behavior, and motor abilities can help provide information about any neurologic deficits. If seizure activity is observed directly, provide a thorough and accurate description of the event. This description needs to include:

- Time of onset and length of seizure activity
- Alterations in behavior such as a cry or changes in facial expression, motor abilities, or sensory alterations prior to the seizure that may indicate an aura
- Precipitating factors such as fever, anxiety, just waking, or eating
- Description of movements and any progression
- Description of respiratory effort and any apnea noted
- Changes in color (pallor or cyanosis) noted
- Position of mouth, any injury to mouth or tongue, inability to swallow, or excessive salivation
- Loss of bladder or bowel control
- State of consciousness during seizure and postictal (after seizure) state—during the seizure the nurse may

TABLE 37.3 Common Anticonvulsant Medications

Medication	Nursing Implications
Phenytoin (IV and PO; IM administration is contraindicated)	Monitor serum levels to ensure therapeutic dosing. Be aware that gingival hyperplasia appears most commonly in children and adolescents. If on prolonged therapy, ensure adequate intake of vitamin D–containing foods. Monitor serum calcium and magnesium levels.
Fosphenytoin (IM or IV only)	Adverse effects are said to be less common than with phenytoin. It does not cause local irritation, but it is a more expensive drug than phenytoin. It is water soluble, therefore allowing faster and easier administration than phenytoin. All dosing is in phenytoin sodium equivalents. It does not precipitate in commonly used IV diluents.
Phenobarbital	Assess for excessive sedation. Monitor serum levels to ensure therapeutic dosing. Monitor for drug interactions. Increase vitamin D–fortified foods or administer supplement if prescribed. Withdrawal symptoms will occur if drug is stopped abruptly. Valproic acid interferes with this drug, causing increased phenobarbital levels.
Felbamate	Monitor for drug interactions, especially if client is taking phenytoin or carbamazepine.
Valproic acid (divalproex sodium, sodium valproate)	Monitor serum levels to ensure therapeutic dosing. Depakote sprinkles are available and useful for children who are unable to tolerate valproate suspension, tablets, or capsules. The contents can be sprinkled on food that does not require chewing.
Carbamazepine	Monitor serum levels to ensure therapeutic dosing; toxicity can occur even with levels slightly above therapeutic range. Plasma concentration decreased by phenytoin, phenobarbital, and valproic acid.
Gabapentin	Do not administer within 2 hours of antacids. Rapidly absorbed in the gastrointestinal tract
Topiramate	Dilantin, tegretol, and valproic acid decrease concentration of topiramate.
Oxcarbazepine	Monitor phenytoin levels if administering concurrently.
Zonisamide	Presence of food will delay absorption. Phenytoin, phenobarbital, and carbamazepine all increase the metabolism of this drug.
Lamotrigine	Valproate inhibits metabolism; therefore, monitor serum blood values and decrease the dose if necessary.
Levetiracetam	Monitor phenytoin levels if administering concurrently. Monitor for difficulty with gait or coordination. B-complex vitamin supplementation can help mange side effects.
Ethosuximide	Give with food GI upset occurs. Monitor closely during periods of dosage adjustment or addition of new medications.

IM, intramuscular; IV, intravenous; PO, by mouth.

BOX 37.1 Nonepileptic Events

- Syncope
- Breath holding
- Jitteriness
- Apnea
- Gastroesophageal reflux
- Cardiac conduction abnormalities
- Migraines
- Tics

ask the child to remember a word; after the seizure, assess if child is able to recall it, to help accurately establish current mental state
- Assess: orientation to person, place, and time; motor abilities; speech; behavior; alterations in sensation postictally
- Duration of postictal state

Laboratory and Diagnostic Tests

Laboratory and diagnostic tests are used to evaluate the cause of, and also aid in identifying the type of, seizure activity (refer to Common Laboratory and Diagnostic

Tests 37.1). Common laboratory and diagnostic studies ordered for the diagnosis and assessment of epilepsy include:

- Serum glucose, electrolytes, and calcium—to rule out metabolic causes such as hypoglycemia and hypocalcemia
- Lumbar puncture (LP)—to analyze CSF to rule out meningitis or encephalitis
- Skull x-ray examinations—to evaluate for the presence of fracture or trauma
- Computed tomography (CT) and magnetic resonance imaging (MRI) studies—to identify abnormalities and intracranial bleeds and rule out tumors
- Electroencephalographs (EEGs)—EEG findings may be noted with certain seizure types, but a normal EEG does not rule out epilepsy because seizure activity rarely occurs during the actual testing time. EEGs are useful in evaluating seizure type and assisting in medication selection. They can be useful in differentiating seizures from nonepileptic activity.
- Video EEGs—provide the opportunity to see the child's actual behavior on video, accompanied with EEG changes; can improve the chance of catching a seizure because the monitoring is done over a period of time

Nursing Management

Nursing management focuses on preventing injury during seizures; administering appropriate medication and treatments to prevent or reduce seizures; and providing education and support to the child and family to help them cope with the challenges of living with a chronic seizure disorder. See Box 37.2 for a list of basic seizure precautions. In addition to the nursing diagnoses and related interventions discussed in Nursing Care Plan 37.1, interventions common to epilepsy follow.

Relieving Anxiety

Seizures produce fear and anxiety due to their unpredictable nature along with the uncontrolled, forceful, and at times violent appearance. Instruct parents and family members, along with those in the community who may care for the child, on how to respond in case of a seizure (see Teaching Guidelines 37.1). This will help to empower the parents, family, and other caregivers, and in turn alleviate some of the anxiety that they may feel.

Managing Treatment

Provide child and family teaching and instruction regarding the administration of anticonvulsant therapy and its importance. Included in this discussion should be common adverse effects, the need to continue the medication unless instructed otherwise by the physician, and the need to call the physician if the child is ill and vomiting and unable to take his or her medication. Encourage parents to discuss unwanted adverse effects with the physician so that they can be addressed and noncompliance with the medication regimen can be reduced. The most common cause of breakthrough seizures is noncompliance.

Providing Family Support and Education

Having a child with a chronic seizure disorder can place stress and anxiety on the family that is often due to fears and misconceptions they may have. An important nursing function is to educate not only the child and family but also the community, including the child's teachers and care-

BOX 37.2 Seizure Precautions

- Padding of side rails and other hard objects
- Side rails raised on bed at all times when child is in bed
- Oxygen and suction at bedside
- Supervision, especially during bathing, ambulation, or other potentially hazardous activities
- Use of a protective helmet during activity may be appropriate.
- Child should wear a medical alert bracelet.

TEACHING GUIDELINES 37.1

How to Respond When Your Child Has a Seizure

Instruct parents and caregivers:

- Remain calm.
- Time seizure episode.
- If child is standing or sitting, ease child to the ground if possible.
- Tight clothing and jewelry around the neck should be loosened if possible.
- Place child on one side and open airway if possible.
- Do not restrain the child.
- Remove hazards in the area.
- Do not forcibly open jaw with a tongue blade or fingers.
- Document length of seizure and movements noted, also cyanosis or loss of bladder or bowel control and any other characteristics.
- Remain with child until fully conscious.
- Call emergency medical services (EMS) if:
  - The child stops breathing
  - Any injury has occurred
  - Seizure lasts for more than 5 minutes
  - This is the child's first seizure
  - Child is unresponsive to painful stimuli after seizure

givers, on the reality and facts of the disorder. Encourage parents to be involved in the management of their child's seizures but to allow the child to learn about the disorder and its management as soon as he or she is old enough. Encourage parents to treat the child with epilepsy just as they would a child without this disorder. Children who are brought up no differently than children without epilepsy will be more likely to develop a positive self-image and have increased self-esteem. Any activity restrictions, such as limiting swimming or participation in sports, will be based on the type, frequency, and severity of the seizures the child has. Educate parents and children on any restrictions and encourage parents to place only the necessary restrictions on the child.

The needs of the child and family will change as the child grows and develops. The nurse needs to recognize theses changes and provide appropriate education and support. Referral to support groups is appropriate. The Epilepsy Foundation can be accessed at www.epilepsyfoundation.org. Additional resources can be found at www.paceusa.org and www.epilepsyinstitute.org.

FEBRILE SEIZURES

Febrile seizures are the most common type of seizure seen during childhood. They usually affect children who are less than 5 years of age, with the peak incidence occurring in children between 18 and 24 months old. It is rare to see febrile seizures in children younger than 6 months and older than 7 years of age. This type of seizure is more commonly seen in boys and there is an increased risk for children who have a family history of febrile seizures. Febrile seizures are associated with a fever, usually related to a viral illness. These seizures are usually benign but can be very frightening for both the child and family. The prognosis is generally excellent for febrile seizures. However, febrile seizures may indicate a serious underlying infectious disease, such as meningitis or sepsis. Though rare, complications associated with febrile seizures include status epilepticus, motor coordination deficits, mental retardation, and behavioral problems.

Therapeutic Management

Treatment includes determination of the cause of the fever and interventions to control the fever. The American Academy of Pediatrics does not recommend long-term or intermittent anticonvulsant therapy for the child who has suffered one or more simple febrile seizures (Shinnar & O'Dell, 2004). Rectal diazepam has been shown to be safe and effective in terminating febrile seizures and may be used in children at high risk for febrile seizures or in children whose parents are extremely anxious. Although anticonvulsant prophylaxis is no longer recommended (Behrman et al., 2004), intermittent use of anticonvulsants at the time of a fever may be used in select groups of children.

Nursing Assessment

A febrile seizure is usually associated with a core temperature that increases rapidly to 39°C (102.2°F) or higher. The seizure usually presents as a generalized tonic-clonic seizure that lasts a few seconds to 10 minutes and is followed by a brief postictal period of drowsiness. A simple febrile seizure is defined as a generalized seizure lasting less than 15 minutes that occurs once in a 24-hour period and is accompanied by a fever. It is likely to have stopped by the time a child receives medical attention. Diagnosis is made based on a thorough history and physical examination, accompanied by a determination of the source of the fever. In some cases an LP may be performed to rule out meningitis or encephalitis. This will be based on the age and the clinical presentation of the child.

Risk factors for recurrence of a febrile seizure include young age at first febrile seizure and family history of febrile seizures and high fever. Children who experience one or more febrile seizures are at no greater risk of developing epilepsy than the general population. No evidence exists that febrile seizures cause structural damage or cognitive declines.

Nursing Management

Provide parental support and education regarding febrile seizures. Reassure parents of the benign nature of febrile seizures. Counsel parents on controlling fever; discuss how to keep a child safe during a seizure; and provide instruction and demonstration in the administration of rectal diazepam at the onset of a seizure (if applicable). Instruct parents when to call their physician and when to take their child to the emergency room. Reinforce that any recurrent seizure activity will require prompt medical attention.

NEONATAL SEIZURES

The incidence of seizures is higher in the neonatal period than in any other age group. The immature brain is more prone to seizure activity. Neonatal seizures are seizures that occur within the first 4 weeks of life and are most commonly seen within the first 10 days. They are different from those in the child or adult because generalized tonic-clonic seizures tend not to occur during the first month of life. Seizures in newborns are associated with underlying conditions such as hypoxic-ischemic encephalopathy, metabolic disorders (hypoglycemia and hypocalcemia), neonatal infection (meningitis and encephalitis), and intracranial hemorrhage. The prognosis depends mainly on the underlying cause of the seizures and the severity of the

insult. There is increasing evidence that neonatal seizures have an adverse effect on neurodevelopment and may predispose the infant to cognitive, behavioral, or epileptic complications later in life.

Therapeutic Management

Acute neonatal seizures should be treated aggressively because repeated seizure activity may result in injury to the brain. Treatment focuses on ensuring adequate ventilation; correcting any underlying metabolic disturbance that may exist, such as hypoglycemia; and possibly administering anticonvulsant therapy. Phenobarbital is often used in the initial management of neonatal seizures but efficacy remains uncertain. The dosage of anticonvulsants may be higher in the neonate because neonates metabolize drugs more rapidly than older infants.

Nursing Assessment

Neonatal seizures may be difficult to recognize clinically and may be accompanied by a normal EEG. Several clinical features may help distinguish seizures from nonepileptic activity, such as tremors or jitteriness, in neonates. Autonomic changes such as tachycardia and elevated blood pressure are common with seizures in neonates, but do not occur with nonepileptic events. Also, nonepileptic movements can be suppressed by gently restraining the limb; in true seizures this is not the case. Ocular deviation may be seen with seizure activity but will not be present with nonepileptic activity. The characteristics of seizures seen in the neonatal period differ from those seen in older children. Five major seizure types have been recognized in the neonatal period. See Table 37.4 for information on types of seizures seen in newborn infants.

Laboratory and diagnostic tests including serum testing (e.g., serum glucose, electrolytes, calcium), LP (to analyze CSF), cranial ultrasound, CT, and MRI may be performed to help determine the cause of the seizures. EEGs and video EEGs may assist in the characterization of neonatal seizures and their medical management.

Nursing Management

Nursing management will focus on carrying out interventions to cease seizure activity; monitoring neurologic status closely; recognizing the seizures; preventing injury during seizure activity; and providing support and education to the parents and family.

Structural Defects

Due to the sensitivity of the development of the neurologic system in the first weeks of embryonic life, there exists a potential for defects to occur. These structural defects include neural tube defects, microcephaly, Arnold-Chiari malformation, hydrocephalus, intracranial arteriovenous malformation, and craniosynostosis.

NEURAL TUBE DEFECTS

Neural tube defects account for the majority of congenital anomalies of the CNS. They affect 0.6 per 1,000 live births in the United States, where there are approximately 3,000 pregnancies annually that are complicated by neural tube defects (Becske & Jallo, 2007; CDC, 2004). They are the second most common major congenital anomaly worldwide, behind cardiac malformations (CDC, 2004). They are serious birth defects of the spine and the brain and include disorders such as spina bifida occulta, myelomeningocele, meningocele, anencephaly, and encephalocele. The neural tube closes between the third and fourth week *in utero*. The cause of neural tube defects is not known but many factors such as drugs, malnutrition, chemicals, and genetics can adversely affect normal CNS development. Strong evidence exists that maternal preconception supplementation of folic acid can decrease the incidence of neural tube defects in pregnancies at risk by 50% (Behrman et al., 2004). In 1992, the United States Public Health Service recommended that all women of childbearing age who are capable of becoming pregnant

TABLE 37.4 TYPES OF SEIZURES SEEN IN NEWBORN INFANTS

Type	Age Affected	Characteristics
Subtle	Preterm and full term	Chewing motions, excessive salivation, alterations in respiratory rate, apnea, blinking, and pedaling movements
Tonic	Preterm	Rigid posturing of the extremities and trunk May be associated with fixed deviation of the eyes
Focal clonic	Full term	Rhythmic twitching of local muscle groups such as the extremities or face
Multifocal clonic	Full term	Similar to focal clonic, except many muscle groups are involved, frequently simultaneously
Myoclonic	Rare in neonatal period	Brief focal jerks, involving one extremity; or multifocal jerks, involving several body parts

take 0.4 mg (400 mcg) of folic acid daily (Merereau et al., 2004). According to the Centers for Disease Control and Prevention (CDC), the number of pregnancies affected by neural tube defects has decreased from 4,000 (1995–1996) to 3,000 (1999–2000) (Merereau et al., 2004). Prenatal screening of maternal serum for alpha-fetoprotein (AFP) and ultrasound examination at 16 to 18 weeks' gestation can help identify fetuses at risk. Anencephaly and encephalocele are discussed below. Refer to Chapter 43 for information on spina bifida occulta, meningocele, and myelomeningocele.

Anencephaly

Anencephaly is a defect in brain development resulting in small or missing brain hemispheres, skull, and scalp. It occurs when the cephalic or upper end of the neural tube fails to close during the third to fourth week of gestation. These infants are born without both a forebrain and a cerebrum, and the condition is incompatible with life. The remaining brain tissue may be exposed. The incidence of anencephaly is 1 in 1,000 live births (Behrman et al., 2004).

Nursing Assessment

Anencephalic infants have a distinctive appearance, with a large defect noted in the vault of the skull (Fig. 37.7). The mother may have had a difficult labor due to the malformation of the head not allowing it to engage in the cervix. The majority of infants will be stillborn. If not, most anencephalic infants die within hours to several days of birth. There have been a few cases in which the infant has lived for several months. The infant is usually blind, deaf, unconscious, and unable to feel pain. Some infants born with anencephaly may be born with a brainstem, but the lack of cerebrum rules out the possibility of gaining consciousness. Reflex actions such as respirations, reactions to sound and touch, and ability to suck may be present.

FIGURE 37.7 Anencephalic infant.

Nursing Management

The prognosis is extremely poor. Nursing management is supportive in nature and focuses on comfort measures for the dying infant. Some parents may have been aware of the diagnosis prenatally due to screening tests such as AFP and ultrasounds. Parents and family will need support and understanding from all health care professionals during this difficult time. Fear of what the child will look like may be overwhelming. Use of an infant cap can be helpful and allow parents to feel more comfortable holding and comforting their infant. Assisting with anticipatory grieving and decision making related to end-of-life care will also be key nursing interventions.

Encephalocele

Encephalocele is a protrusion of the brain and meninges through a skull defect. It results from failure of the anterior portion of the neural tube to close. Infants born with an encephalocele are at risk for visual problems, microcephaly, mental retardation, and seizures. The prognosis, including the extent of complications and cognitive deficits, will depend on the size and location of the encephalocele and involvement of other brain structures. Encephaloceles are often accompanied by craniofacial and other abnormalities such as hydrocephalus, microcephaly, spastic quadriplegia, ataxia, developmental delay, mental and growth retardation, and seizures. Some children who are affected may display normal intelligence.

Treatment consists of surgical repair, including placement of tissues back into the skull and removal of the sac; possible shunt placement to correct associated hydrocephalus; and corrective repair of any craniofacial abnormalities.

Nursing Assessment

Initial assessment postdelivery will reveal a visible external sac protruding from the skull area. It occurs most commonly in the occipital region but can occur elsewhere, such as frontally or nasofrontally. Generally the lesion is covered by skin, but it may also be open. Therefore, assessment to ensure that the sac covering is intact remains important. Assess neurologic status carefully. Before surgical correction, the infant will be thoroughly examined to determine brain tissue involvement or associated anomalies. Diagnostic procedures such as CT, MRI, and ultrasound may be performed.

Nursing Management

Nursing management will consist of preoperative and postoperative care, along with symptomatic and supportive care. Preoperative and postoperative care will be similar to that for the child with myelomeningocele, with a focus on preventing rupture of the sac, preventing infection, and providing adequate nutrition and hydration. Infants with an encephalocele are at an increased risk for developing hydrocephalus Therefore, monitor for signs and symptoms of increased ICP and head circumference.

MICROCEPHALY

Microcephaly is defined as a head circumference that is more than three standard deviations below the mean for the age and sex of the infant (Behrman et al., 2004). It may be congenital or it may be acquired and develop in the first few years of life. It generally results in mental retardation due to the lack of functioning brain tissue. There are many causes. Microcephaly can be caused by abnormal development during gestation or follow intrauterine infections such as rubella, toxoplasmosis, and cytomegalovirus. It can also be caused by chromosomal abnormalities or be associated with other syndromes. Acquired microcephaly may occur due to severe malnutrition, perinatal infections, or anoxia in early infancy.

Nursing Assessment

Microcephalic infants will present at birth with a normal or reduced head size. As the child ages, head growth will fail while the face will continue to grow at a normal rate. This results in a small head, a large face, and a loose, often wrinkled scalp. As the child grows older, this smallness of the skull becomes more pronounced. Development of motor functions and speech may be delayed. The degree of mental retardation varies, but it is a common occurrence. Convulsions may be present, and motor deficit ranges from clumsiness to spastic quadriplegia.

Nursing Management

There is no treatment. Nursing care will be supportive and focus on determining the extent of neurologic and cognitive deficits, as well as teaching parents the care of a child with such impairments.

ARNOLD-CHIARI MALFORMATION

Arnold-Chiari malformation consists of two major subgroups—type I and type II. In type I, symptoms are typically seen in adolescence and adulthood. This type is usually not associated with hydrocephalus and is the more benign form. The deformity is a result of the cerebellar tonsils displacing into the upper cervical canal. The client will usually complain of neck pain, recurrent headaches, lower extremity spasticity, and urinary frequency. Type II is the most common and is usually associated with hydrocephalus and myelomeningocele. The deformity results from the cerebellum, the medulla oblongata, and the fourth ventricle displacing into the cervical canal, resulting in an obstruction of the CSF and causing hydrocephalus. The prognosis depends on the extent of the defect. Symptomatic type II Chiari malformation is the leading cause of death in infants and young children with open neural tube defects (Stevenson, 2004). Treatment of the type II Chiari malformation includes surgical decompression.

Nursing Assessment

Approximately 10% of type II Arnold-Chiari malformations result in symptoms in infancy (Behrman et al., 2004). Symptoms consist of weak cry, stridor, and apnea. These symptoms require prompt medical treatment to reduce mortality. Gastrointestinal disturbances along with a history of chronic aspiration, choking, gagging, prolonged feeding times, and weight loss may also be present. Physical signs include coarse upper airway sounds heard on auscultation and diminished or absent gag reflex. In the older child, signs and symptoms seen are subtler and less frequently life threatening. Upper extremity weakness, spasticity, ataxia, and headaches are frequent signs found. Assessment of shunt function is extremely important in the infant and older child presenting with type II Chiari malformation and associated hydrocephalus (refer to "Hydrocephalus" section). An MRI may be performed to help evaluate and diagnose Chiari malformations.

Nursing Management

Nursing management will focus on preoperative and postoperative care; preventing infection; monitoring of blood loss; improvement of preoperative symptoms in the postoperative period; any signs and symptoms of increased ICP; and any resultant CNS injury.

HYDROCEPHALUS

Hydrocephalus is not a specific disease, but results from underlying brain disorders. It is one of the most frequently seen disorders of the nervous system. It results from an imbalance in the production and absorption of CSF. In hydrocephalus, CSF accumulates within the ventricular system and causes the ventricles to enlarge and increases in ICP to occur. Common disorders or illnesses that are associated with hydrocephalus include neural tube defects such as myelomeningocele; intraventricular hemorrhage in premature infants; meningitis; intrauterine viral infections; lesions or malformations of the brain such as posterior fossa brain tumors; Chiari malformations; and nonaccidental injury. Hydrocephalus may be congenital or acquired. Congenital hydrocephalus is present at birth

and is often due to environmental influences during fetal development or a genetic disposition. Causes of congenital hydrocephalus include abnormal intrauterine development, as is the case with myelomeningocele, or intrauterine infections. Acquired hydrocephalus develops at the time of birth or at some point after. It can occur at any age and can result from injury or disease. Acquired hydrocephalus can result from trauma, hemorrhage, neoplasms, or infections.

Hydrocephalus is also classified as obstructive or noncommunicating vs. nonobstructive or communicating. Obstructive or noncommunicating hydrocephalus occurs when the flow of CSF is blocked within the ventricular system. Neural tube defects, neonatal meningitis, trauma, tumors, or Chiari malformations usually result in this type of hydrocephalus. One of the most common causes of obstructive or noncommunicating hydrocephalus in children is aqueductal stenosis, which results from the narrowing of the aqueduct of Sylvius (a passageway between the third and fourth ventricles in the middle brain). Nonobstructive or communicating hydrocephalus occurs when the flow of CSF is blocked after it exits from the ventricles. This form of hydrocephalus, in which the CSF can still flow between the ventricles, is most often caused by defective absorption of CSF. Examples include hydrocephalus that results from subarachnoid hemorrhage and intrauterine infections.

Prognosis for the child with hydrocephalus depends mainly on the cause and whether or not brain damage has occurred prior to recognition and treatment. These children are at increased risk for developmental disabilities, visual problems, abnormalities in memory, and reduced intelligence. Long-term follow-up and multidisciplinary care are necessary.

Pathophysiology

CSF is formed primarily in the ventricular system by the choroid plexus. It flows as a result of the pressure gradient that exists between the ventricular system and the venous channels. CSF is absorbed primarily by the arachnoid villi. Hydrocephalus results when there is an obstruction in the ventricular system or obliteration or malfunction of the arachnoid villi. This results in impaired absorption or circulation of the CSF. In rare cases, hydrocephalus can be caused by an overproduction of CSF by the choroid plexus.

Therapeutic Management

Hydrocephalus must be identified early. Treatment needs to be initiated in order to prevent brain tissue damage that can result from the increased ICP that hydrocephalus creates. Specific treatment will depend on the cause. The goals of treatment include relieving hydrocephalus and managing complications associated with the disorder, such as growth and developmental delay. With few exceptions, most cases of hydrocephalus are treated with the surgical placement of an extracranial shunt. Most often a ventriculoperitoneal shunt (VP shunt) is placed. See Figure 37.8 for an illustration of a shunt. The shunt will need to be replaced as the child grows. Therefore, the child will undergo shunt revision surgery at various times during his or her life. It is important for health care professionals and parents to be able to recognize when a shunt needs replacing or when complications are occurring, to decrease the possibility of death or disability that may occur due to increased ICP.

FIGURE 37.8 To treat hydrocephalus, a ventriculoperitoneal (VP) shunt catheter is placed in an enlarged ventricle. The shunt diverts the flow of cerebrospinal fluid (CSF) within the central nervous system to the peritoneum, where CSF is now absorbed across the peritoneal membrane into the body's circulation.

Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1140. Assessment findings pertinent to hydrocephalus are discussed below.

Health History

Explore the pregnancy history and past medical history for:

- Intrauterine infections
- Prematurity with intracranial hemorrhage
- Meningitis
- Mumps encephalitis

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history of the undiagnosed child might include:

- Irritability
- Lethargy
- Poor feeding
- Vomiting
- Complaints of headache in older children
- Altered, diminished, or changes in LOC

Children known to have hydrocephalus are often admitted to the hospital for shunt malfunctions or other complications of the disease. The health history should include questions related to:

- Neurologic status—have there been changes or decreases in LOC; changes in personality; deterioration in school performance?
- Complaints of headache
- Vomiting
- Visual disturbances
- Any other changes in physical or cognitive state

Physical Examination

Physical examination of the infant or child with hydrocephalus will include inspection and observation; palpation; and percussion.

Inspection and Observation

Observe general appearance and affect. Pay particular attention to the size of the skull and note any asymmetry. Note LOC and motor function. Changes or decreases in LOC may be noted along with brisk reflexes and spasticity of the lower extremities. Symptoms seen vary by age, primarily due to the fact that the infant's skull is able to accommodate the buildup of CSF because the sutures have not closed. In the infant, the most obvious indication is often a rapid increase in head circumference (Fig. 37.9). In the older child, loss of development and changes in personality may be seen. Signs and symptoms associated with increased ICP may be seen (refer to Comparison Chart 37.1).

Palpation

In the infant, palpation of the fontanels may reveal wide-open, bulging fontanels. They will be nonpulsatile and feel tense and very full.

Percussion

Upon percussion of the skull, by advanced practitioners, a positive Macewen's sign may be noted. This is when a "cracked pot" sound is heard during percussion and can indicate separation of the sutures.

Laboratory and Diagnostic Tests

Common laboratory and diagnostic tests ordered for the diagnosis and assessment of hydrocephalus include:

- Skull x-ray studies (may reveal separation of sutures)
- CT
- MRI

CT and MRI are used to evaluate for the presence of hydrocephalus and can also aid in identifying the cause of hydrocephalus. Refer to Common Laboratory and Diagnostic Tests 37.1.

▶ *Consider THIS!*

Sandra and Michael Graham have brought their 6-month-old son, Thomas, to the pediatric unit for observation. Thomas's head circumference has increased from the 25th percentile at the 4-month check-up to the 75th percentile at the 6-month check-up. Upon assessment, the nurse notes a bulging anterior fontanel and persistent primitive reflexes.

What do you think is going on?
Identify early signs.
Identify late signs.
Describe nursing care for Thomas.
What teaching will the nurse do with Sandra and Michael?

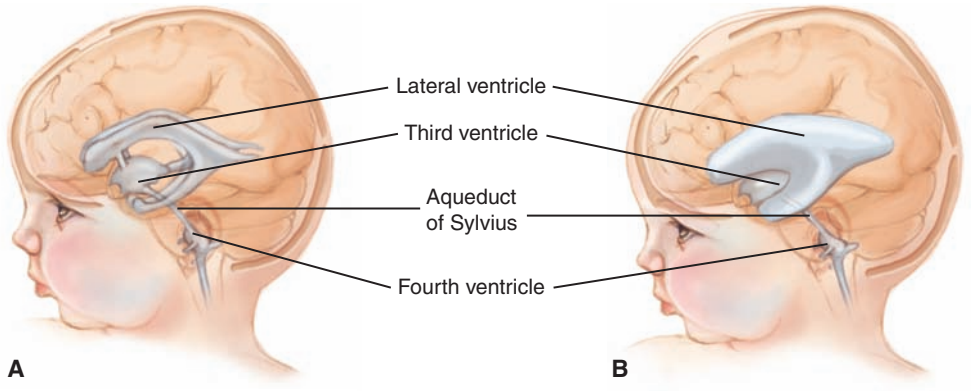

FIGURE 37.9 (**A**) Infant without hydrocephalus. (**B**) Infant with hydrocephalus. Note broadening of the forehead and large head size.

Nursing Management

Nursing management of the child with hydrocephalus will focus on maintaining cerebral perfusion, minimizing neurologic complications, maintaining adequate nutrition, promoting growth and development, and supporting and educating the child and family. In addition to the nursing diagnoses and related interventions discussed in Nursing Care Plan 37.1, interventions common to hydrocephalus are discussed below.

Preventing and Recognizing Shunt Infection and Malfunction

The major complications associated with shunts are infection and malfunction. Due to the serious nature and potentially devastating affects of shunt infection or malfunction, parents and health professionals need to be aware of the signs and symptoms to provide early recognition and prompt treatment. Signs and symptoms of a shunt infection include elevated vital signs, poor feeding, vomiting, decreased responsiveness, seizure activity, and signs of local inflammation along the shunt tract. Signs and symptoms of shunt malfunction include vomiting, drowsiness, and headache. Signs and symptoms of increased ICP, as listed in Comparison Chart 37.1, can also be indicative of shunt complications. See Evidence-Based Practice 37.1.

Infection can occur at any time but is more common 1 to 2 months after placement. Infection is treated with intravenous antibiotics and, if the infection is persistent, the shunt will be removed and an external ventricular drainage (EVD) system will be put into place until the CSF is sterile (refer to Common Medical Treatments 37.1 and Box 37.3).

▶ *Take* NOTE!

Rapid drainage of CSF, which may occur if the client sits up without the EVD system being clamped, will decrease ICP and can lead to extreme headache, collapse of the ventricles, formation of subdural hematomas, and neurologic deterioration.

A new shunt will be placed after the infection has cleared. Intrathecal administration of antibiotics may be performed by the physician or advanced practitioner. Keeping the peritoneal surgical incision free of feces and

EVIDENCE-BASED PRACTICE 37.1

Clinical Features, Pathogens, and Outcomes of Patients With CSF Shunt Infections

Infection is the most common complication of shunt implantation. Infections of the CNS are a major cause of morbidity and mortality in patients with shunts. Treatment of shunt infections usually results in an increase in hospital stay by 2 or 3 weeks. Many factors have been attributed to increasing the risk of infection, including age, cause of hydrocephalus, type of shunt implanted, and the surgeon's experience.

● Study

A chart review was performed on 124 consecutive patients having a CNS shunt placed over a 4-year period. The patients were analyzed according to age, etiology of hydrocephalus, prognosis, clinical infection features, and clinical outcome. Among these 124 patients, 22 (17.7%) were determined to have a shunt infection.

▲ Findings

The most common causes of hydrocephalus in patients with an infected shunt were congenital hydrocephalus-myelomeningocele (32%) and meningitis (23%). The most common causative microorganism was *Staphylococcus aureus.* The rate of infection did not differ greatly between type of shunt placed. Children, especially those under 2 years, were more likely than adults to acquire a shunt infection. Fever was the most common symptom noted. Presentation of other manifestations such as nausea, vomiting, malaise, and headache was variable.

■ Nursing Implications

Intraoperative nurses must follow strict aseptic technique during surgical insertion or repair of shunts. Postoperatively, closely monitor the child for signs and symptoms of infection, especially fever. In the child with suspected shunt infection, ensure that CSF examination and blood cultures are performed prior to administration of antibiotics. Timely administration of antibiotic treatment according to the antimicrobial susceptibility and sensitivity is imperative.

Sacar, S., Turgut, H., Toprak, S., Cirak, B., Coskun, E., Yilmaz, O., & Tekin K. (2006). A retrospective study of central nervous system shunt infections diagnosed in a university hospital during a 4-year period [Electronic Version]. *BMC Infectious Disease.* Retrieved December 27, 2007 online at http://www.pubmedcentral.nih.gov/articlerender.fcgi?artid=1421408.

BOX 37.3 Nursing Management of External Venticular Drainage (EVD) Device

- Ensure all connections are secure and label line as EVD.
- Regularly check that drip chamber of manometer is set at the height prescribed in relation to the client (i.e., zero at clavicle).
- Clamp the drain in the event of client movement or movement anticipated with care. Rezero and open clamps when done.
- Accurately document volume and color of CSF every hour (CSF is normally clear and colorless; cloudiness indicates infection). Notify MD or charge nurse of any significant increase in amount of drainage (if exceeds 10 mL more than previous volumes).
- If minimal or no drainage, check tubing for kinks, blockage, or closed clamps. Check to see if CSF is oscillating in tubing. If blockage is suspected, notify neurosurgery department immediately.
- Entry site into skull should be dressed with a sterile occlusive dressing and should be changed if soiled or nonocclusive.
- Routine CSF samples may be sent for culture and analysis.
- Client may be taking prophylactic antibiotics due to increased risk of infection from the drain.

urine can help prevent infection. Additionally, inspect surgical incisions after shunt placement for signs and symptoms of infection and any signs of leaking CSF.

Malfunction of the shunt can occur due to kinking, clogging, or separation of the tubing. Blockage is the most common reported complication. A shunt that has been placed within the past year is at higher risk of malfunction. Early recognition and operative intervention are essential to prevent neurologic deficits or possible death from occurring.

Supporting and Educating the Child and Family

Hydrocephalus is a serious and chronic illness. It will require lifelong follow-up and regular evaluations. It requires early recognition of complications to prevent neurologic damage. Children will require future surgeries and hospitalizations, which can place a strain on the family and its finances. Potential growth and developmental disabilities are an additional strain. The support of the family in establishing realistic goals and helping the child to achieve his or her developmental and educational potential is important.

The family should be involved in the child's care from the time of diagnosis. Initially parents may be frightened because shunt placement involves entering the brain. Provide parents with accurate information regarding the procedure, and be available to listen to parents' concerns and to answer questions that arise. Ongoing education about the illness and its treatment are important, including signs and symptoms of shunt complications. As the family becomes more comfortable with the diagnosis, treatment, and signs and symptoms of complications, they will become experts on the child's care and will often recognize subtle changes in him or her that may be indicative of shunt complications. Referral to support groups can be helpful for both the family and the child. The National Hydrocephalus Foundation can be accessed at www.nhfonline.org. Additional resources can be found at www.hydroassoc.org and www.hydrocephalus.org.

INTRACRANIAL ARTERIOVENOUS MALFORMATION (AVM)

Intracranial arteriovenous malformation is a rare congenital disorder. It is caused by an abnormal development of blood vessels and can occur in the brain, brainstem, or spinal cord. AVMs that hemorrhage can lead to serious neurologic deficits and even death. However, some cases of AVMs never cause problems. AVMs are the most common cause of hemorrhagic stroke in infants (Molofsky, 2006).

Therapeutic Management

More aggressive treatment strategies are used in children. Treatment options used include surgical excision; endovascular embolization, which involves closing off the vessels of the AVM by injecting glue into them; and radiosurgery, which involves focusing radiation on the AVM. The treatment approach will be based on the age of the client and size and location of the malformation in the brain. The client will usually require at least 24 hours of intensive care monitoring following surgery.

Nursing Assessment

The most common symptoms seen include intracranial hemorrhage (children are more likely to present with hemorrhage than adults), seizures, headaches, and progressive neurologic deficits such as vision problems, loss of speech, problems with memory, and paralysis. In children less than 2 years of age, presentation may include cardiac failure due to arteriovenous shunting in neonates and infants; a large head secondary to hydrocephalus; and seizure activity. Diagnosis is made using diagnostic imaging procedures such as MRI, CT, and arteriography. Due to advances in brain imaging techniques, an increasing number of AVMs are detected before rupture.

Nursing Management

Nursing management for these clients is aimed at supportive care. Monitor for changes in neurologic status, noting any seizure activity, signs or symptoms of increased ICP, or signs and symptoms of intracranial hemorrhage. Hydrocephalus may occur as a result of intracranial hemorrhage secondary to the AVM. An EVD and eventual shunt placement may be necessary (refer to "Hydrocephalus" section).

CRANIOSYNOSTOSIS

Craniosynostosis is premature closure of the cranial sutures (Fig. 37.10). Complete closure of all sutures does not normally occur until late in childhood. Premature closure can inhibit brain growth and a distorted skull appearance will be evident. In cases where only one suture is fused, neurologic impairments are rarely seen. When two or more sutures are fused, neurologic complications such as hydrocephalus with increased ICP are more likely to occur. The incidence of craniosynostosis is approximately 1 in 2,000 births (Behrman et al., 2004). The cause is unknown, but in 10% to 20% of cases a genetic disorder such as Carpenter's syndrome or Apert's, Crouzon's, or Pfeiffer's disease is present (Behrman et al., 2004). There are numerous different types of craniosynostosis; they are listed and illustrated in Table 37.5. The prognosis is good for the majority of infants presenting with craniosynostosis, and normal brain development will occur. Exceptions to this are the infant or child who has associated genetic disorders that involve brain function and development.

Surgical correction may be done and allows for normal expansion of the brain and acceptable appearance of the head and skull. If one suture is fused, the surgical intervention is done mainly for cosmetic reasons. If more than one suture is fused, operative intervention is essential to prevent neurologic complications.

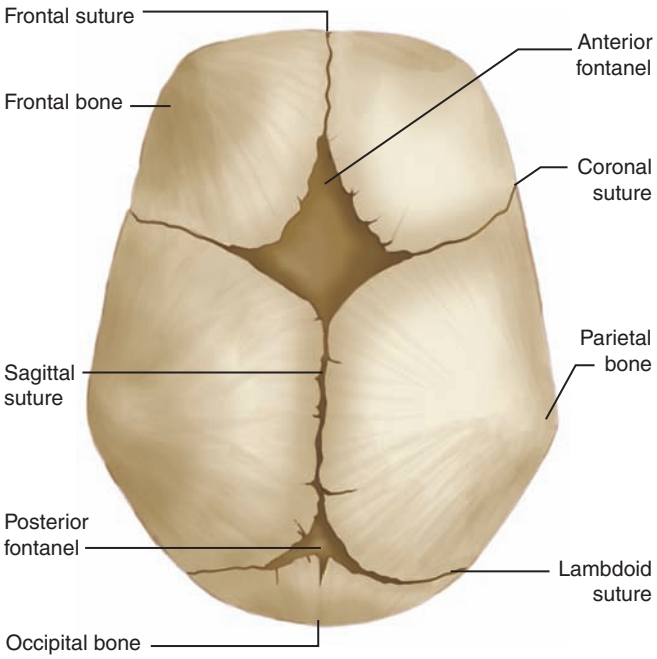

FIGURE 37.10 Skull sutures in the infant.

Nursing Assessment

Most cases of craniosynostosis are present at birth. Skull deformity is evident as well as a prominent bony ridge that can be palpated. X-ray studies can confirm fusion of the sutures. It is important that craniosynostosis be detected early if it is not evident at birth because premature closure of the suture lines will inhibit brain development. Therefore, measure head circumference in all children less than 3 years old and compare findings with normal head circumference parameters as well as past measurements of the infant or child.

Nursing Management

Nursing management includes observing hemoglobin and hematocrit levels due to large volumes of blood loss that can occur, and observing for pain, hemorrhage, fever, infection, and swelling. Due to the location of the surgery and incision line, large amounts of facial swelling may be present. This can result in an inability of the child to open his or her eyes for a few days postoperatively. Make sure that parents are aware of this. Encourage the parents to talk to, hold, and comfort their child during this time. Provide support and education to the parents before, during, and after the procedure. Refer families to the Craniosynostosis and Positional Plagiocephaly Support Group, accessible at www.cappskids.org/index.html and 6905 Xanadu Court, Fredericksburg, VA 22407.

POSITIONAL PLAGIOCEPHALY

Since the inception of the "back to sleep" program, which recommends placing all infants supine to sleep to decrease the risk of sudden infant death syndrome (SIDS), there has been a dramatic increase in the incidence of positional plagiocephaly. Positional plagiocephaly refers to asymmetry in head shape without fused sutures. It results from gravitational force exertion on the developing cranium. Plagiocephaly in the infant may lead to torticollis.

Medical treatment for positional plagiocephaly is generally conservative, such as changing the infant's position, encouraging "tummy time," and avoiding excessive use of the car seat for infant seating outside of the automobile. Some infants may benefit from the use of a molding helmet (Fig. 37.11).

TABLE 37.5 Types of Craniosynostosis

Types	Description	
Sagittal synostosis (scaphocephaly)	Sagittal suture is closed. Head grows long and narrow in anterior–posterior direction. Broad forehead and a prominent occiput are present. Most common form	Metopic synostosis (trigonocephaly)	Metopic suture is closed. Usually a ridge down the forehead can be seen or felt. Triangular-shaped forehead Eyebrows may appear "pinched" on either side. Eyes may also appear close together.	
Unilateral coronal synostosis (anterior plagiocephaly)	Early closure of one side of the coronal suture Forehead and orbital rim (eyebrow) have a flattened appearance on that side.	
Bicoronal synostosis (brachycephaly)	Very flat, recessed forehead Skull is shortened in the anterior–posterior direction. Commonly seen in Apert's and Crouzon's disease	Lambdoid (posterior plagiocephaly)	Early closure of one lambdoid suture Trapezoid-shaped head in craniosynostosis. Similar to shape found in positional molding or positional plagiocephaly	
Nursing Assessment

View the infant's head from the top, noting asymmetry ranging from flattening on one side posteriorly to posterior flattening associated with anterior bulging (Fig. 37.12). Assess neck range of motion to determine if torticollis is also present. Palpate the cranial sutures, which will not feel overlapped as they do when they are fused. Skull x-ray examination or head CT scan will rule out craniosynostosis by demonstrating evidence of open sutures.

Nursing Management

Nursing management is directed toward repositioning the infant to decrease time spent with the flattened area in the dependent position. Position the infant so that turning

FIGURE 37.11 Molding helmet for positional plagiocephaly.

away from the affected side is necessary for him or her to view objects of interest. Place the infant on the abdomen when awake and supervised. Discourage use of the car seat outside of the automobile. Place a rolled washcloth along the affected side of the head to discourage turning the head in that direction. Following these recommendations may prevent positional plagiocephaly in the infant without congenital torticollis.

FIGURE 37.12 Note flattening of the right posterior parietal and occipital regions of the skull in this infant with positional plagiocephaly.

Infectious Disorders

Infectious disorders of the neurologic system include bacterial meningitis, aseptic meningitis, encephalitis, Reye's syndrome, botulism, and rabies.

BACTERIAL MENINGITIS

Bacterial meningitis is an infection of the meninges, the lining that surrounds the brain and spinal cord. It is a serious illness in children and can lead to brain damage, nerve damage, deafness, stroke, and even death. It requires rapid assessment and treatment. The leading cause of bacterial meningitis in newborns is group B streptococcus and gram-negative enteric bacilli like *Escherichia coli* (Spiro & Spiro, 2004). In children, the leading causative agents are *Neisseria meningitidis* and *Streptococcus pneumoniae* (Spiro & Spiro, 2004). See Table 37.6 for types of meningitis seen in different age groups. In developed countries, disease resulting from *Haemophilus influenzae* type B, once the most common cause of meningitis in children, has decreased dramatically since the introduction of the Hib vaccine. In less developed countries, infection with *H. influenzae* type B still remains a concern. Most cases of bacterial meningitis occur in the winter and early spring, but it can occur year round (Spiro & Spiro, 2004).

Pathophysiology

Bacterial meningitis causes inflammation, swelling, purulent exudates, and tissue damage to the brain. It can occur as a secondary infection to upper respiratory infections, sinus infections, or ear infections, and can also be the result of direct introduction through LP; skull fracture or severe head injury; neurosurgical intervention; congenital structural abnormalities, like spina bifida; or the presence of foreign bodies, like a ventricular shunt or cochlear implants.

TABLE 37.6 Common Causes of Meningitis in Different Age Groups

Causative Organism	Age Affected
Escherichia coli	Newborns and infants
Streptococcus group B	Infants less than 1 month old
Haemophilus influenzae type B	1 month–6 years, typically 6–9 months old
Streptococcus pneumoniae	Children older than 3 months of age and adults
Neisseria meningitidis	Children older than 3 months of age and adults

Therapeutic Management

Bacterial meningitis is a medical emergency and requires prompt hospitalization and treatment. Deterioration may be rapid and occur in less than 24 hours, leading to long-term neurologic damage and even death. Intravenous antibiotics will be started immediately after the LP and blood cultures have been obtained if bacterial meningitis is suspected. The length of therapy and specific antibiotic will be determined based on the analysis and the culture and sensitivity of the CSF. Corticosteroids may be ordered to help reduce the inflammatory process. Specific medical treatment varies based on the suspected causative organism and will be determined by the physician.

Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1140. Assessment findings pertinent to bacterial meningitis are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Sudden onset of symptoms
- Preceding respiratory illness or sore throat
- Presence of fever, chills
- Headache
- Vomiting
- Photophobia
- Stiff neck
- Rash
- Irritability
- Drowsiness
- Lethargy
- Muscle rigidity
- Seizures

Symptoms in infants can be more subtle and atypical, but the history may reveal:

- Poor sucking and feeding
- Weak cry
- Lethargy
- Vomiting

Explore the client's current and past medical history for risk factors such as:

- Young age: 1 month to 5 years, with most cases in children less than 1 year of age and young adults 15 to 24 years of age
- Any fever or illness during pregnancy or around delivery (for infants less than 3 months of age)
- Exposure to ill persons
- Exposure to tuberculosis
- Travel history
- History of maternal illness
- Recent neurosurgical procedure or head trauma
- Presence of a foreign body, such as a shunt or a cochlear implant
- Immunocompromised status
- Close-contact living spaces such as dormitories or military bases
- Daycare attendance

Physical Examination

Observe the general appearance of the client. The infant with bacterial meningitis may rest in the **opisthotonic** position (Fig. 37.13), and the older child may complain of neck pain. In the infant a bulging fontanel may be present, which is often a late sign, and the infant may be consolable when lying still as opposed to being held. Presence of positive Kernig's and Brudzinski's signs can indicate irritation of the meninges (Fig. 37.14). Inspect the client for presence of a rash; a petechial, vesicular, or macular rash may be seen.

▶ ***Take*** *NOTE!*

Abrupt eruption of a petechial or purplish rash can be indicative of meningococcemia (infection with N. meningitidis*). Immediate medical attention is warranted.*

Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of bacterial meningitis include:

- LP—Fluid pressure will be measured and a sample is obtained for analysis and culture. CSF will reveal increased white blood cells (WBCs) and protein and low glucose (the bacteria present feed on the glucose).
- Complete blood count (CBC)—WBCs will be elevated.
- Blood culture—Performed to rule out sepsis. Blood culture will be positive in cases of septicemia.

FIGURE 37.13 Infant in opisthotonic position: head and neck are hyperextended to relieve discomfort.

Figure 37.14 (**A**) Kernig's sign is tested by flexing legs at the hip and knee (**A1**), then extending the knee (**A2**). A positive report of pain along the vertebral column is a positive sign and indicates irritation of meninges. (**B**) Brudzinski's sign is tested by the child lying supine with the neck flexed (**B1**). A positive sign occurs if resistance or pain is met. The child may also passively flex hip and knees in reaction, indicating meningeal irritation (**B2**).

Nursing Management

Quickly initiate supportive measures to ensure proper ventilation, reduce the inflammatory response, and help prevent injury to the brain. Interventions are aimed at reducing ICP and maintaining cerebral perfusion along with treating fluid volume deficit, controlling seizures, and preventing injury that may result from altered LOC or seizure activity. Initiate appropriate isolation precautions. In addition to standard precautions, infants and children diagnosed with bacterial meningitis will be placed on droplet isolation until 24 hours of antibiotics have been received to help prevent transmission to others. Refer to Nursing Care Plan 37.1 for nursing diagnoses and related interventions. In addition to those diagnoses and interventions, reducing fever and preventing bacterial meningitis should be noted.

Reducing Fever

Hyperthermia related to infectious process, increased metabolic rate, and dehydration as evidenced by increased body temperature; warm, flushed skin; and tachycardia may be present. Reducing fever is important to help maintain optimal cerebral perfusion by reducing the metabolic needs of the brain. Administer antipyretics such as acetaminophen and NSAIDS such as ibuprofen, per order. Institute nonpharmacologic measures if needed. Reduction of environmental temperature and the use of cooling blankets, fans, cold compresses, and tepid baths may be helpful in reducing fever. Avoid measures that cause shivering because it increases heat production and is therefore counterproductive as well as uncomfortable for the client.

Preventing Bacterial Meningitis

Bacterial meningitis is a serious illness and prevention is important. It is transmitted by direct close contact with respiratory droplets from the nose or throat. Most at risk are those living with the client or anyone with whom the client played or was in close contact. Postexposure prophylaxis and postexposure immunization may be effective. Control measures should be initiated in environments where risk exists. Disinfect toys and other shared objects to decrease transmission of the microorganisms to others.

To reduce group B streptococcus infection in neonates, screen pregnant women; if the screening results

are positive, administer intrapartal antibiotics. Vaccines are available for some specific causative organisms, but complete vaccination prevention is not possible at this time. The Hib vaccine is routine starting at 2 months of age and all children should be immunized to continue the reduction of bacterial meningitis caused by *H. influenzae* type B. The pneumococcal vaccine is also routine for all children starting at 2 months of age and should be considered for preschoolers who are at risk. Children at risk include those with immune deficiency; sickle-cell disease; asplenia; chronic pulmonary, cardiac, or renal disease; diabetes mellitus; cochlear implants; cerebrospinal leaks; and organ transplants.

Since the 1990s, a dramatic increase in the incidence of meningococcal meningitis (and the often fatal blood infection meningococcemia) among adolescents and young adults has occurred. Living in close quarters, sleeping less than usual, and sharing personal items such as drinking glasses and lip balm contribute to the increase in disease. For these reasons, the AAP recommendations advise meningococcal vaccination for all children aged 11 to 12 years; adolescents at high school entry or age 15 (whichever comes first) who have not been previously vaccinated; all college freshmen living in dormitories; and children who are at high risk, such as children with chronic conditions or immune suppression or those who travel to high-risk areas or live in crowded conditions (AAP, 2005). Further information and a resource for families can be obtained through the National Meningitis Association, which can be accessed at www.nmaus.org. (See Healthy People 2010.)

ASEPTIC MENINGITIS

Aseptic meningitis is the most common type of meningitis, and the majority of children affected are less than 5 years of age. If the causative organism can be identified, it is usually a virus. Enteroviruses, like echovirus and coxsackievirus, account for many cases of aseptic meningitis. Less common causes include mumps, herpesvirus, human immunodeficiency virus (HIV), measles, varicella, and polio.

HEALTHY PEOPLE 2010

Objective	Significance
Reduce bacterial meningitis in young children.	• Encourage appropriate immunization as recommended. • Educate families to complete prescribed courses of antibiotics (to avoid progression of minor bacterial infections to meningitis).

Therapeutic Management

Prompt diagnosis and treatment are essential to improve outcomes. The child is treated aggressively as if he or she has bacterial meningitis until the diagnosis is confirmed. Antibiotics are administered and continued until the causative organism is recognized. If the cause is viral, antibiotics may be discontinued and antiviral agents may be started at this time. After diagnosis is confirmed, treatment is mainly supportive in nature and the illness is usually self-limiting, lasting 3 to 10 days.

Nursing Assessment

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- General malaise
- Headache
- Photophobia
- Poor feeding
- Nausea
- Vomiting
- Irritability
- Lethargy
- Neck pain
- Positive Kernig's and Brudzinski's signs

The onset of symptoms may be abrupt or gradual. Assessment is similar to that of the child with bacterial meningitis. Signs and symptoms are similar to those seen in bacterial meningitis, but the child is usually less ill.

Nursing Management

Nursing management is similar to the nursing care of the child with bacterial meningitis and will focus on comfort measures to reduce pain and fever. Aseptic meningitis can be managed successfully at home if the child's neurologic status is stable and he or she is tolerating oral intake.

ENCEPHALITIS

Encephalitis is an inflammation of the brain that may also include an inflammation of the meninges. It is a rare complication and can be caused by protozoan, bacterial, fungal, or viral invasion. In children it is most often associated with a viral illness. Most cases of viral encephalitis in children are of unknown cause. In the United States, common causative organisms include the herpes simplex virus; enteroviruses, such as poliovirus and coxsackievirus; and arthropod-borne viruses. Arthropod-borne viruses (e.g., West Nile and St. Louis encephalitis) are spread by the bites of insects, especially mosquitoes and ticks. Enteroviral infections are usually seen in the late summer and early fall, and arthropod-borne viruses are seen in the summer months.

Recovery from encephalitis can occur in a few days or may be complicated and involve severe neurologic damage with residual effects. Prognosis depends on the age of the child and the causative organism. Prompt diagnosis and treatment are essential. The child suspected of having encephalitis should be hospitalized. Treatment is mainly supportive in nature and focuses on maintaining optimal cerebral perfusion; hydration and nutrition; and injury prevention.

Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1140. Assessment findings pertinent to encephalitis are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Fever
- Flu-like symptoms
- Altered LOC
- Headache
- Lethargy
- Drowsiness
- Generalized weakness
- Seizure activity

Explore the client's current history for risk factors such as:

- Recent travel
- Recreational activities, such as hiking and camping
- Animal contacts

Physical Examination

Perform a neurologic examination to distinguish between encephalitis and viral meningitis. In encephalitis, a neurologic examination will reveal changes in sensorium and focal neurologic changes. Neurologic findings vary and reflect the areas of the brain that are involved.

Laboratory and Diagnostic Tests

An LP may be done and the CSF may show an elevated leukocyte count and elevated protein and glucose levels. However, in some cases, levels may be normal. MRI, CT, and EEG procedures may be performed to help identify early changes and provide useful clues in developing a diagnosis.

Nursing Management

Nursing management is similar to nursing care for the child with meningitis. Teach children and their families how to prevent encephalitis. Encephalitis can result from complications of childhood illnesses such as measles, mumps, or chickenpox. Explain the importance of keeping children up-to-date in their immunizations. Effective vaccines are available for a few viral pathogens that cause encephalitis (such as rabies virus and Japanese encephalitis virus), but these vaccines are not routine; they are recommended for those at high risk. For example, postexposure rabies vaccines can be administered to a child who was bitten by a suspected rabid animal. Also, those traveling to areas where Japanese encephalitis is endemic, such as India and China, and planning a prolonged stay or extreme outdoor activity should receive the appropriate vaccine. Vector control and avoiding mosquito and tick bites are the best prevention of arthropod-borne infection. Using insect repellent (repellents containing DEET should be used cautiously in children less than 12 years of age and not at all in children less than 1 year of age); wearing clothing that covers the arms and legs; controlling mosquito populations by eliminating areas of standing water where mosquitoes can breed; and using insect traps and public measures such as sprayed insecticides to reduce the mosquito population can all be helpful in reducing the risk of infection with arthropod-borne viruses. Specific antiviral therapy may be used for diseases caused by the herpes simplex virus.

REYE'S SYNDROME

Reye's syndrome is a disease that primarily affects children less than 15 years of age who are recovering from a viral illness. The exact cause of Reye's syndrome is unknown. It has been found that Reye's syndrome is a reaction that is triggered by the use of salicylates or salicylate-containing products to treat a viral infection. This reaction causes brain swelling, liver failure, and death in hours if treatment in not initiated. In the 1980s, the adverse effects of salicylates used to treat viral illnesses began to be publicized and the U.S. Food and Drug Administration (FDA) required warning labels to be placed on all salicylate-containing products, such as aspirin. Since then there has been a dramatic decrease in the occurrence of Reye's syndrome.

Nursing Assessment

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Severe and continual vomiting
- Changes in mental status
- Lethargy
- Irritability
- Confusion
- Hyperreflexia

Explore the client's current and past medical history for risk factors such as:

- A prodromal viral illness, like chickenpox, croup, flu, or an upper respiratory infection
- Ingestion of salicylate-containing products within 3 weeks of the start of the viral illness

Diagnosis can be confirmed by elevated liver function tests and elevated serum ammonia levels.

Nursing Management

Early recognition and treatment are the most important aspects of managing this illness. Nursing management is aimed at maintaining cerebral perfusion, managing and preventing increased ICP, providing safety measures due to changes in LOC and risk for seizures, and monitoring fluid status to prevent dehydration and overhydration.

Education is an important aspect of preventing this disease. Salicylates are found in many products, including many over-the-counter products such as Alka-Seltzer and Pepto-Bismol. For a complete list, go to www.reyessyndrome.org. Recovery from Reye's syndrome is dependent on the severity of swelling of the brain; some children will make a full recovery, while others may suffer long-term neurologic damage.

BOTULISM

Botulism is a disease that is caused by a toxin produced in the immature intestines of young children resulting from infection with the bacteria *Clostridium botulinum*. It is rare, but can cause serious paralytic illness. Botulism is mainly a food-borne infection but can also be contracted through wound infections or intestinal infections in infants. *C. botulinum* is common in soil and can also be found in a variety of foods, such as improperly preserved home-canned foods. It generally occurs in infants less than 6 months of age. It has been associated with feeding honey and corn syrup to infants; thus these should be avoided in children less than 1 year of age. The disease is not contagious, and the child must ingest the bacterial spores. These spores then multiply in the intestinal tract and produce the toxin, which is absorbed in the immature intestines of the infant. It is generally not a problem for older children because the bacteria do not grow well in mature intestines due to the presence of the normal intestinal flora. Prognosis is good, but if treatment is not initiated, paralysis to the arms, legs, trunk, and respiratory system can develop.

Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1140. Assessment findings pertinent to botulism are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Signs and symptoms usually occur soon after ingestion of the bacteria. Common signs and symptoms in infants reported during the health history might include:

- Constipation
- Poor feeding
- Listlessness
- Generalized weakness
- Weak cry

Common signs and symptoms in older children reported during the health history might include:

- Double vision
- Blurred vision
- Drooping eyelids
- Difficulty swallowing
- Slurred speech
- Muscle weakness

Physical Examination and Laboratory and Diagnostic Tests

Assess for a diminished gag reflex, which is indicative of botulism. Diagnostic tests include culturing of stool and serum. Botulism is a rare disease and is difficult to diagnose because symptoms are similar to those seen in other neurologic diseases. Therefore assessment may include diagnostic tests to help rule out other diseases such as Guillain-Barré syndrome, stroke, and myasthenia gravis.

Nursing Management

Treatment is mainly supportive in nature and focuses on maintaining respiratory status and nutritional status. If ordered, administer botulism toxin early in the course of the disease to reduce the severity and progression of the disease.

Trauma

Trauma or injury is a leading cause of childhood morbidity and mortality in the United States, with the highest rates among minority populations (Morbidity and Mortality Weekly Report, 2007). The child faces significant risk of trauma to his or her developing neurologic system, often leading to neurologic disorders with life-threatening and lasting effects. Neurologic trauma may include head trauma, nonaccidental head trauma, and near drowning.

HEAD TRAUMA

In the United States, injury causes more death in children than disease. Of these injuries, head injury is the most common cause of death and disability in childhood.

Common causes of head trauma in children include falls, motor vehicle accidents, pedestrian and bicycle accidents, and child abuse. Many factors make children more susceptible to head trauma than adults. Larger head size in relation to the body, coupled with a higher center of gravity, causes the child to hit his or her head more readily when involved in motor vehicle accidents, bicycle accidents, and falls. Children are also at risk for injury related to psychosocial factors such as their high activity level, curiosity, incomplete motor development, and their lack of knowledge and judgment skills. Also, their dependence on others to care for them places them at a high risk for injuries caused by child abuse. Children younger than 3 years of age have a very mobile spine, especially in the cervical region, along with immature neck muscles. This places them at a higher risk for injury from acceleration/deceleration injuries, which occur when the head receives a blow or is shaken; the sudden acceleration causes deformation of the skull and movement of the brain, allowing brain contents to strike parts of the skull. Bruising of the brain can occur at the point of impact or at that point distant from the impact where the brain collides with the skull. Another result of brain movement is hemorrhages in the brain, which are caused by the shearing forces that may tear small arteries. The child's thin skull places him or her at increased risk for skull fractures and penetrating injuries resulting from head trauma.

Head trauma is a broad term that can include specific patterns of injury. See Table 37.7 for descriptions of common head injuries seen in children. Head trauma in children is serious because it can cause an immediate threat to the child's life as well as a number of complications that can lead to lifelong impairment of an individual's physical, cognitive, and psychosocial functioning. Prognosis for the child who has suffered a head trauma depends on the extent and severity of the injury as well as any complications (see Healthy People 2010).

Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1140. Assessment findings pertinent to head trauma are discussed below.

Health History

Take a detailed history, including past medical history along with details of the events surrounding the injury such as mental status at the time of the injury, any loss of consciousness, irritability, lethargy, abnormal behavior, vomiting (if so, how many times), any seizure activity, and any complaints of headache, visual changes, or neck pain.

Physical Examination

Perform a thorough physical examination. Initial physical assessment will focus on the ABCs (airway, breathing, and circulation) (refer to Chapter 52 for further information on emergency management). All children who experience head trauma need an assessment of their neurologic function as soon as they are seen. This includes LOC, pupillary response, and any seizure activity. Fixed and dilated pupils, fixed and constricted pupils, or sluggish pupillary reaction to light will warrant prompt intervention.

▶ Take NOTE!

A child's spine must remain stabilized after a head injury until spinal cord injury is ruled out.

Laboratory and Diagnostic Tests

Diagnostic tests that may be utilized include x-ray examinations of the head and neck and CT and MRI scans. These procedures can assist in providing a more definitive diagnosis of the severity and type of trauma.

▶ Take NOTE!

If clear liquid fluid is noted draining from the ears or nose, notification of the physician or advanced practitioner is warranted. If the fluid tests positive for glucose, this is indicative of leaking CSF.

Nursing Management

Nursing management of the child with head trauma depends on the seriousness of the injury. For all head trauma, however, the nurse provides support and education to the family and provides teaching on ways to prevent future head injuries.

Caring for the Child With Mild to Moderate Head Injury

Most children with mild to moderate closed head injury, which refers to brain injury without any penetrating injury to the brain, who suffered no loss of consciousness, no other injury to their head or body, are acting normally after the injury, and were healthy before the injury can be cared for and observed at home. Provide parents and caregivers with clear instructions regarding the care of their child at home. Explain that they must seek medical attention if the child's condition worsens at any time

TABLE 37.7 Common Head Injuries Seen in Children

Types	Description	Characteristics
Skull fractures	A break in the bone surrounding the brain	In infants and children less than 2 years old, a great deal of force is needed to produce a skull fracture. Due to the flexibility of the immature skull, it is able to withstand a great degree of deformation before a fracture will occur. Can result in little or no brain damage, but may have serious consequences if the underlying brain tissue is injured
Linear skull fracture	A simple break in the skull that follows a relatively straight line	Most common skull fracture. Can result from minor head injuries such as being struck by a rock, stick, or other object; falls; or motor vehicle accidents. Not usually serious unless there is additional injury to the brain
Depressed skull fractures	The bone is locally broken and pushed inward, causing pressure on the brain.	Can result from forceful impact from a blunt object, such as a hammer or another heavy but fairly small object Surgery is often required to elevate the bony pieces and inspect the brain for evidence of injury.
Diastatic skull fracture	A fracture through the skull sutures	Most commonly occurs in the lamboid sutures (refer to Fig. 37.10 for location of sutures) Usually treatment is not required but observation will be necessary.
Compound skull fracture	A laceration of the skin and splintering of the bone	The fracture can be linear or depressed. Generally is the result of blunt force. Usually requires medical intervention and surgery may be necessary.
Basilar skull fracture	A fracture of the bones that form the base of the skull	Can result from severe blunt head trauma with significant force. Due to the proximity to the brainstem, this is a serious head injury. Findings include CSF rhinorrhea and otorrhea, bleeding from the ear, and orbital or postauricular ecchymosis (bruising behind ear is referred to as Battle's sign), and these children are at increased risk for infection because the fracture may allow a portal of entry into the central nervous system.
Concussion	A mild brain injury that is caused by jarring or shaking and results in disruption or malfunction of the electrical activities of the brain	Most common head injury. Results from a blow or jolt to the head caused by sports injuries, motor vehicle accidents, and falls. Confusion and amnesia after the head injury are seen. Loss of consciousness may or may not occur. Noted symptoms may include increased distractibility, and difficulty with concentration. Treatment includes rest and monitoring for neurologic changes that could indicate a more severe injury, such as increased sleepiness, worsening headache, increased vomiting, worsening confusion, difficulty walking or talking, changes in LOC, and seizures.
Contusion	Bruising of cerebral tissue	Results from a blow to the head from incidents such as a motor vehicle accident, falls, or abuse such as shaken baby syndrome. May cause focal disturbances in vision, strength, and sensation. The signs and symptoms will vary based on the extent of vascular injury and can range from mild weakness to prolonged unconsciousness and paralysis. Treatment includes close monitoring for neurologic changes. Surgery is usually not necessary.

(continued)

TABLE 37.7 Common Head Injuries Seen in Children (continued)

Types	Description	Characteristics
Subdural hematoma	Collection of blood between the dura and cerebrum	Low incidence of fracture. Most common in children less than 2 years old, especially infants. Results from birth trauma, falls, bicycle injuries, and abuse such as shaken baby syndrome. Usually consists of venous bleeding. Symptoms may occur within 3 days of trauma or as late as 20 days. Symptoms include vomiting, failure to thrive, changes in LOC, seizures, and retinal hemorrhage. Treatment depends on clinical symptoms, size of clot, and area of the brain involved. In some cases, the bleed may be closely monitored for resolution. In other cases, treatment may include subdural taps in infants and surgical evacuation in older children. Close monitoring of neurologic status and for signs of increased ICP is indicated.
Epidural hematoma	Collection of blood located outside the dura but within the skull	Relatively uncommon. Often results from skull fracture. Seen when head trauma is severe. Usually arterial bleeding, therefore brain compression occurs rapidly and can result in impairment of the brainstem and respiratory or cardiovascular function. Symptoms include vomiting, headache, and lethargy. Treatment depends on clinical symptoms, the size of the clot, and the area of the brain involved. Treatment includes prompt surgical evacuation and cauterization of the artery. The earlier the bleed is recognized and treated, the more favorable the outcome. Close monitoring of neurologic status is indicated.

during the first several days after injury. See Teaching Guidelines 37.2.

Children with mild closed head injury may exhibit some cognitive and behavioral symptoms, such as difficulty paying attention, problems making sense of what has been seen or heard, and forgetting things, in the early days after the injury. The majority make a full recovery. However, some may experience ongoing cognitive and behavioral difficulties, including slow information processing and attention difficulties.

Caring for the Child With Severe Head Injury

Children with more severe head injury may require intensive care initially until stabilized. Focus will be on maintaining the child's airway; monitoring breathing, circulation, and neurologic status closely; preventing and ceasing any seizure activity; and treating any other injuries that may have occurred as a result of the trauma. Nursing management will continue to focus on evaluation of neurologic status, assessing for changes in LOC and signs and symptoms of increased ICP. Initiate seizure precautions as ordered.

Individualize care to the specific needs of the child. Maintain a quiet environment to help reduce restlessness and irritability. Manage pain and administer sedation as ordered. Observe the level of sedation closely to ensure that LOC will not become altered, which would hinder the ability to assess adequately for neurologic changes. Monitor for the development of complications, which include hemorrhage, infection, cerebral edema, and herniation.

HEALTHY PEOPLE 2010

Objective	Significance
Increase the number of states and the District of Columbia with laws requiring bicycle helmets for bicycle riders.	• Support legislation locally that calls for bicycle helmet laws. • Participate in local "safe kids" activities to demonstrate support for helmet use

▶ **Take** NOTE!

Parents are extremely helpful resources in evaluating a child's behavior for changes or abnormalities. They can provide insight into whether a behavior seen is normal or abnormal for this child. Examples include the ease at which a child is normally aroused, how much the child normally sleeps during the day, and what is the child's normal visual and hearing acuity.

TEACHING GUIDELINES 37.2

Monitoring the Child with Closed Head Injury at Home

Instruct parents and caregivers:

- Stay with the child for the first 24 hours and be ready to take the child to the hospital if necessary.
- Closely observe the child for a few days.
- Wake the child every 2 hours to ensure that he or she moves normally, wakes enough to recognize the caregiver, and responds to the caregiver appropriately.
- Call the medical provider or bring child to the emergency room if the child exhibits any of the following:
  - Constant headache that gets worse
  - Slurred speech
  - Dizziness that does not go away or happens repeatedly
  - Extreme irritability or other abnormal behavior
  - Vomiting more than two times
  - Clumsiness or difficulty walking
  - Oozing blood or watery fluid from ears or nose
  - Difficulty waking up
  - Unequal-sized pupils
  - Unusual paleness that lasts longer than 1 hour
  - Seizures
- Review signs and symptoms of increased intracranial pressure and provide parents with a number they can call if they have questions or concerns.

Head injuries can range from a temporary unconsciousness that resolves quickly to children who may remain in a comatose state for a prolonged time. Nursing management of the comatose child is similar to nursing care of the comatose adult.

Providing Support and Education

Provide support and education for the family of a child who has suffered a head trauma. Encourage involvement in the child's care. The extent of residual neurologic damage and recovery may be unclear for the child with a head injury. This can be frustrating and stressful for parents and family. Encourage verbalization of their feelings and concerns. Rehabilitation of the child with permanent brain damage is an essential component of his or her care. It should begin as soon as possible in the hospital setting and may continue for months to years. This can place a strain on the family and its finances. Families need to be involved in the rehabilitation process. The nurse will be a key member in ensuring the parents and family are involved with the interdisciplinary team.

Preventing Head Injuries

Prevention of head injuries provides the greatest benefit to children and the community. Nurses play a key role in educating the public on topics such as helmet use with certain sports; bicycle and motorcycle safety; seat belt use; and providing adequate supervision of children to help prevent injuries and accidents—and resultant head trauma—from occurring (see Healthy People 2010).

NONACCIDENTAL HEAD TRAUMA

In the United States, inflicted or nonaccidental head trauma is the leading cause of traumatic death and morbidity during infancy (Berger et al., 2006). Causes include violent shaking, referred to as shaken baby syndrome (SBS); blows to the head; and intentional cranial impacts against the wall, furniture, or the floor. The infant's large head size and weak neck muscles place him or her at an increased risk for head trauma due to violent shaking or cranial impacts from adults. The average victim is less than 9 months of age. SBS is a form of child abuse and a significant number of head traumas result from it. It differs from many other forms of child abuse in that frequently there was no intent to harm the child. Shaking happens when the parent or caregiver becomes frustrated or angry because he or she cannot get the baby to stop crying.

The full appearance of neurologic deficits resulting from nonaccidental head trauma may take several years to be identified and recovery can be very slow. Long-term outcomes are not known, but many of these infants and children have poor outcomes and may suffer neurologic defects such as profound mental retardation, spastic quadriplegia, severe motor dysfunction, and blindness. The majority of children with inflicted head injuries have some impairment of motor and cognitive abilities, language, vision, and behavior. These injuries may also contribute to later problems with education and social attainment.

HEALTHY PEOPLE 2010

Objective	Significance
Reduce hospitalization for nonfatal head injuries.	• Educate children and families about safety such as helmet use when inline skating, skateboarding, bicycling, and playing football or other sports that may result in head injury. • Encourage appropriate child car seat and seat belt use. • Use every encounter with a child and family as an opportunity to provide education related to injury prevention.

Nursing Assessment

The infant who has been a victim of nonaccidental trauma can present in many ways. Symptoms and physical findings may be similar to those seen in children with accidental head trauma or increased ICP related to infection. Therefore many nonaccidental traumas remain unidentified. Nurses are mandatory reporters of abuse (for further information on this, see Chapter 52), and early recognition of suspected child abuse is essential to prevent death and disability from repetitive inflicted head trauma.

Health History

It is important that health care providers review the child's history closely and pay particular attention to the caregivers' explanation of the child's injury. The health care provider should be alert to any discrepancies between the physical injuries and the history of injury given by the parent, if the stories are conflicting, or if the caregivers are unable to give an explanation for the injury. Also, any previous intracranial or skeletal injuries that cannot be explained should be noted.

In less severe cases, common signs and symptoms may include:

- Poor feeding or sucking
- Vomiting
- Lethargy or irritability
- Failure to thrive
- Increased sleeping
- Difficulty arousing

In more severe cases, the symptoms will be more acute and may consist of:

- Seizure activity
- Apnea
- Bradycardia
- Decreased LOC
- Bulging fontanel

Physical Examination

External bruising of the head and face may be evident in some inflicted head traumas. However, no evidence of external trauma, but the presence of intracranial or intraocular hemorrhages, is the classic presentation of SBS. Retinal hemorrhages are seen in the majority of cases, which is a rare finding in accidental or nontraumatic events.

Laboratory and Diagnostic Tests

Diagnostic tests including CT, MRI, ophthalmologic examination to rule out retinal hemorrhages, and skeletal survey x-rays to rule out or confirm other injuries may be performed to help determine the extent and type of injury.

Nursing Management

Treatment and nursing management will be similar to that for the child with accidental head trauma (see earlier section, "Head Trauma"). Prevention of nonaccidental head trauma, including SBS, is a major concern for all health care professionals. Be aware of risk factors related to the potential for SBS to occur. Recognizing these risk factors will allow appropriate intervention and protection of the child to take place. See Box 37.4 for risk factors related to SBS.

Educating parents and caregivers on appropriate ways to handle stress and ways to cope with a crying infant can help to prevent nonaccidental head trauma (see Teaching Guidelines 37.3). Many parents and caregivers may perceive shaking a child as a less violent way to react than other means of enforcing discipline. They need to be aware that shaking a baby, even for only a few seconds, can cause serious brain damage and death. Decreasing mortality and morbidity associated with SBS and nonaccidental injury through early preventive education is an essential nursing concern. Information about the dangers of shaking a baby should be a part of prenatal care and standard discharge teaching on postpartum units. In addition, this information should be provided to the community and in health education classes to reach young potential child care providers.

NEAR DROWNING

Drowning rates have declined, but drowning remains a leading cause of injury-related death in children between the ages of 1 and 19 years (Schnitzer, 2006). Drowning is a preventable problem that is far too prevalent, especially in children. Those at greatest risk of drowning are toddlers and adolescent males.

Near drowning is described as an incident in which a child has suffered a submersion injury and has survived for at least 24 hours. Near-drowning events result in a significant number of injured children and can result in long-term neurologic deficits. In children between the ages of 1 and 4 years, most drowning and near-drowning incidents occur in residential swimming pools (Saluja et al., 2006). Most incidents are accidental and result from inadequately supervising children who are in or near water; lack of use of personal flotation devices while on recreational water apparatus such as boats; and diving accidents.

BOX 37.4 Risk Factors Associated with Shaken Baby Syndrome

- Single parent
- Young parent
- Substance abuse by a parent
- Any external factors present such as financial, social, or physical burdens that place stress on the parent
- Premature or sick infant
- Infant with colic

TEACHING GUIDELINES 37.3

Tips to Calm a Crying Baby

Instruct parents and caregivers
- Try to figure out what is upsetting the baby.
  - Is the baby hungry?
  - Is the baby's diaper dry?
  - Is the baby cold or hot?
  - Is the baby overtired or overstimulated?
  - Is the baby in pain?
  - Is the baby sick or running a fever?
- Try to help the baby relax.
  - Turn down the lights.
  - Swaddle the baby.
  - Walk the baby.
  - Rock the baby.
  - Give the baby a breast, bottle, or pacifier.
  - Shhh, talk to, or sing to the baby.
  - Talk the baby for a stroller or car ride.
- Sometimes the baby may continue to cry after all your efforts. If you feel overwhelmed, frustrated, or angry, focus on keeping the baby safe.
  - Stop what you are doing, take a deep breath, and count to 10.
  - Place the baby in a safe place, such as the crib or playpen.
  - Leave the room and shut the door, and find a quiet place for yourself.
  - Check on the baby every 5–15 minutes.
  - Do not be afraid to call for help; call a friend, relative, or neighbor.

Nursing Assessment

Hypoxia is the primary problem resulting from near drowning. Nursing assessment needs to begin with resuscitative measures. The child may be comatose, hypothermic, lack spontaneous respirations, and present with hypoxia and hypercapnea. Gain information about the site of submersion (was it fresh or salt water), the water temperature, the time of submersion, and how long it was until the child received interventions such as cardiopulmonary resuscitation (CPR) and emergency medical services (EMS).

Nursing Management

Resuscitative measures should be started as soon as the child is pulled from the water, and the child should be transported to a hospital immediately. Management will be based on the degree of cerebral insult that has occurred. The child who has been successfully resuscitated will usually require intensive nursing care and monitoring. Promotion of oxygenation and monitoring for infection related to aspiration of water are primary nursing concerns. Chronic neurologic damage occurs in many near drownings secondary to hypoxia. The child may need rehabilitation and long-term follow-up. Provide parents with support and education relating to their child's condition. Educating children, families, and the community is an important nursing intervention to help prevent drowning (see Teaching Guidelines 37.4).

Blood Flow Disruption

The incidence of pediatric cerebral vascular disorders is estimated to be between 2 and 3 per 100,000 with the highest incidence in the younger child (Molofsky, 2006). Although they occur less often than in adults, they are still an important cause of mortality and chronic morbidity in children. Many children will develop lifelong cognitive and motor impairments. Improvements in imaging techniques have led to an increase in the reported incidence and prevalence of cerebral vascular disorders in children in recent years. Childhood cerebral vascular disorders (stroke) are usually seen after the first month of life. Periventricular/intraventricular (PVH/IVH) hemorrhage is seen in preterm infants and in infants up to 1 month of age (refer to Chapter 24 for further information on PVH/IVH).

CEREBRAL VASCULAR DISORDERS (STROKE)

A cerebral vascular disorder is a sudden disruption of the blood supply to the brain. It affects neurologic functioning, such as movement and speech. Two major types of cerebral vascular disorders are seen in children just as in adults: ischemic stroke and hemorrhagic stroke. Ischemic stroke is more common than hemorrhagic stroke in children. In children, there is a wide array of risk factors and

TEACHING GUIDELINES 37.4

Teaching to Prevent Drowning

Instruct parents and caregivers
- Install proper pool fencing.
- Start water safety training at a young age.
- Never leave an infant or young child without adult supervision in or near water (this includes bathtubs).
- Empty water from all containers, such as 5-gallon buckets, immediately after use.
- Use personal flotation devices at all times when near water.
- Learn cardiopulmonary resuscitation (CPR) and keep emergency numbers handy (make sure babysitters are CPR qualified).
- Know the depth of water before permitting a child to jump or dive.

causes as compared to adults (see Comparison Chart 37.2), but in many cases the cause remains unidentified. The outcomes reported for cerebral vascular disorders in children vary, but many children will develop some neurologic or cognitive deficit.

Nursing Assessment

The clinical presentation will vary according to age, the underlying cause, and the location of the stroke. Signs and symptoms of acute stroke are similar to those seen in the adult and depend on the area of the brain that has been affected. Common signs include:

- Weakness on one side or hemiplegia
- Facial droop
- Slurred speech
- Speech deficits

Strokes in children are diagnosed in the same manner as strokes in adults. However, further tests may need to be run in the child, such as metabolic studies, coagulation tests, echocardiogram, and LP to help identify the cause of the stroke.

Nursing Management

Historically, children have been excluded from adult stroke studies. Therefore, many treatments used in children have had to be adapted from adult studies. Acute treatment is supportive and requires intensive care. The exact treatment will depend on the underlying cause. Nursing management will be similar to that for the adult client who has suffered a stroke. Care will focus on assessing neurologic status, increasing mobility, providing adequate nutrition and hydration, and encouraging self-care. Rehabilitative care may be initiated, depending on the long-term deficits, to help the child attain optimal function. Parental support and education will be essential in helping them care for a child who has new disabilities..

Chronic Disorders

Chronic disorders in children necessitate multidisciplinary care. Parents and children are in need of a large amount of education and support from the health care team. Chronic neurologic disorders commonly seen in children include headaches and breath holding.

HEADACHES

Acute and chronic headaches, including migraines, are common reasons why children miss school, visit their primary care physicians, and receive subsequent referrals to neurologists. Children with reports or symptoms of headaches need to be examined thoroughly. Headaches may result from sinusitis or eyestrain or can be indicative of more serious conditions such as brain tumors, acute meningitis, or increased ICP. Migraines are a specific

COMPARISON CHART 37.2 Risk Factors and Causes of Stroke in the Pediatric Client vs. the Adult Client

	Risk Factors and Causes in Children	Risk Factors and Causes in Adults
Ischemic stroke	Cardiac disorders and intracardiac defects (congenital such as ventricular septal defect, atrial septal defect, and aortic stenosis, or acquired such as rheumatic heart disease) Coagulation abnormalities that lead to thrombosis Sickle-cell disease Infection, such as meningitis Arterial dissection Genetic disorders	Cardiac disease, including atherosclerosis Diabetes mellitus Hyperlipidemia Hypercoagulability states Polycythemia Sickle-cell disease Smoking Increased age Male gender Obesity Excessive alcohol consumption
Hemorrhagic stroke	Vascular malformations such as intracranial arteriovenus malformation (AVM) Aneurysms Warfarin therapy Cavernous malformations Malignancy Trauma Coagulation disorders such as hemophilia Thrombocytopenia Liver failure Leukemia Intracranial tumors such as medulloblastomas	Hypertension Aneurysms Use of anticoagulant medications Smoking Increased age Male gender Obesity Excessive alcohol consumption

type of headache. They are benign, recurrent, throbbing headaches often accompanied by nausea, vomiting, and photophobia. Acute migraines can occur in children as young as 3 to 4 years old. The cause of migraine headaches is not well understood.

Therapeutic Management

After other acute or chronic conditions are ruled out, management will focus on treating the child's pain. Pharmacologic measures may be utilized in the treatment of chronic headaches and migraines. Medications used in children to treat and prevent headaches are similar to the medications used to treat adults. Recent attention has been paid to headaches caused by medication overuse. The client may have a primary headache disorder that is exacerbated by the frequent use of medications. Although medication overuse headaches are common in children, they are frequently underrecognized and underdiagnosed.

Nursing Assessment

Elicit a description of the present illness and chief complaint. Important health history information to obtain is onset of the pain, aggravating and alleviating factors, frequency and duration of the pain, time of day the pain usually occurs, location of the pain, and quality and intensity of the pain.

In young children, symptoms of headache may be hard to recognize. However, common signs and symptoms may include:

- Irritability
- Lethargy
- Head holding
- Head banging
- Sensitivity to sound or light

Assessment also includes a thorough physical examination to rule out any life-threatening illness, such as a brain tumor or increased ICP. A detailed neurologic exam is warranted. Neuroimaging may be performed based on the child's history and physical exam, if needed, to rule out a brain tumor or mass as the cause of the headaches.

Nursing Management

Nursing measures will focus on support and education. Reassure the child and family that no serious medical or neurologic disease is present. Because headaches are recurring and the cause may be unknown, pain management can be difficult. Provide education to help the child and parents gain control over the headaches. Teach the child and family to a keep very accurate record of headaches and activities surrounding the headaches to help establish a pattern of occurrence and identify triggering factors. Encourage parents and the child to recognize the triggering factors and to avoid them (Box 37.5). Teach the child and family about pain medications and how to use them. Teach other management techniques, which may include exercise, regular attendance at school, use of biofeedback, stress reduction techniques, and possible psychiatric assessment.

BOX 37.5 Potential Headache Triggers

- Foods, such as chocolate, caffeine, or monosodium glutamate (MSG)-containing foods
- Changes in hormone levels, around menses and ovulation
- Changes in:
  - Weather
  - Season
  - Sleep patterns
  - Meal schedule
- Stress
- Intense activity
- Bright or flickering lights
- Odors, such as strong perfumes

BREATH HOLDING

Breath holding is a benign behavior of childhood, although it is extremely frightening for parents. It is normally seen in children 1 to 3 years old and typically is outgrown by 5 years of age. It is usually triggered by the child becoming angry or stressed after not getting his or her way. It can also occur as a reflexive response to fear, pain, or being startled. The child stops inhaling and exhaling or hyperventilates, the brain becomes anoxic, and the child becomes cyanotic and then passes out. It usually resolves spontaneously. With the loss of consciousness the child will begin breathing on his or her own and will often begin crying, screaming, and trying to catch his or her breath. The spells usually only last 30 to 60 seconds and, as long as the child does not sustain an injury while falling, have no consequences.

Nursing Assessment

The first time a spell occurs, a doctor should evaluate the child because the event could indicate a seizure. Breath holding also has been shown to be aggravated by iron deficiency anemia and, in rare cases, it could indicate a more serious neurologic condition and therefore warrant a full evaluation. Elicit a full description of the episode and events leading up to it. Also, collect a thorough past medical history and perform a complete physical examination.

Nursing Management

If no underlying condition is found, the child needs no therapy. Nursing management should focus on educating and supporting the parents. Breath holding is a scary event and

parents will want information on the effects of the behavior and how to prevent the behavior from recurring. Reassure parents that the child will suffer no ill effects from breath holding and that they should not reinforce the breath holding behavior or give in to the child. Encourage parents to maintain a safe environment when an episode is occurring, but to avoid giving extra attention to the child after the event because this could encourage repetition of the behavior.

Key Concepts

- Development of the brain and spinal cord occurs early in gestation, in the first 3 to 4 weeks. Infection, trauma, teratogens, and malnutrition during this period can result in malformations and may affect normal CNS development.
- The brain of the newborn is highly vascular, leading to an increased risk for hemorrhage.
- The head of the infant and young child is large in proportion to the body and the neck muscles are not well developed, which places the infant at an increased risk of head injury from falls and accidents.
- Neurologic disorders in children can result from congenital problems as well as infections or trauma.
- LP and CSF analysis can be useful in the diagnosis of hemorrhage, infection, or obstruction.
- CT and MRI studies can be useful in diagnosing congenital abnormalities such as neural tube defects, hemorrhage, tumors, fractures, demyelinating, or inflammation.
- EEGs measure the electrical activity of the brain and can be used in diagnosing seizures or brain death.
- Antibiotics are utilized in the treatment of bacterial meningitis and shunt infections.
- Anticonvulsants are used in the treatment and prevention of seizures and are often used in combination.
- Corticosteroids are used to reduce cerebral edema and must be tapered before discontinuing.
- Risk factors associated with neurologic disorders include prematurity, difficult birth, infection during pregnancy, family history of genetic disorders with a neurologic manifestation, seizure disorders, and headaches.
- Alterations in motor function, such as changes in gait or muscle tone or strength, may indicate certain neurologic problems such as increased ICP, head injury, and cerebral infections.
- Increased ICP is a sign that may occur with many neurologic disorders. It may result from head trauma, birth trauma, hydrocephalus, infection, and brain tumors. It is essential that the nurse observes for signs and symptoms associated with increased ICP while caring for a child with a potential or suspected neurologic disorder.
- Sunset eyes may indicate increased ICP as seen in hydrocephalus.
- A bulging fontanel can be a sign of increased ICP and is seen in such neurologic disorders as hydrocephalus and head traumas.
- Cortical control of motor function is lost in certain neurologic disorders; postural reflexes reemerge and are directly related to the area of the brain that is damaged. Decorticate posturing occurs with damage of the cerebral cortex. Decerebrate posturing occurs with damage at the level of the brainstem.
- Hydrocephalus results from an imbalance in the production and absorption of CSF. Key assessment findings include a rapid increase in head circumference seen in the infant, or loss of development and changes in personality in the older child. Signs and symptoms associated with increased ICP may be seen.
- Bacterial meningitis requires rapid assessment and treatment. On assessment, the nurse may find the infant with bacterial meningitis resting in the opisthotonic position, and the older child may complain of neck pain.
- Nursing management of seizures focuses on preventing injury during seizures, instituting seizure precautions, maintaining a patent airway, administering appropriate medication and treatments to prevent or reduce seizures, and providing education and support to the child and family to help them cope with the challenges of living with a chronic seizure disorder.
- Nursing management of the child with hydrocephalus will focus on maintaining cerebral perfusion, minimizing neurologic complications, recognizing and preventing shunt infection and malfunction, maintaining adequate nutrition, promoting growth and development, and supporting and educating the child and family.
- Nursing management of the child with bacterial meningitis will include administration of intravenous antibiotics, reducing ICP, and maintaining cerebral perfusion along with treating fluid volume deficit, controlling seizures, and preventing injury that may result from altered LOC or seizure activity.
- Nurses play a key role in educating the public on topics such as helmet use with certain sports, bicycle and motorcycle safety, seat belt use, and providing adequate supervision of children to help prevent injuries and accidents and resultant head trauma from occurring.
- Many neurologic disorders affect multiple body systems with lifelong deficits that require long-term rehabilitation. Adjusting to the demands this condition places on the child and family is difficult. Parents may need time to accept their child's condition but as soon as possible they should be involved in the child's care.
- Children with neurologic disorders and their families often need large amounts of education and support throughout the child's lifetime. As the child grows, the needs of the family and child will change. The nurse needs to provide ongoing education and support.
- Some neurologic disorders require complete intensive daily care. Adjusting to these demands can be difficult for the family. Encourage respite care and provide meaningful education programs that emphasize independence for the child in the least restrictive educational environment.

Refer caregivers to local resources, including education services and support groups.

Chapter Worksheet

Multiple Choice Questions

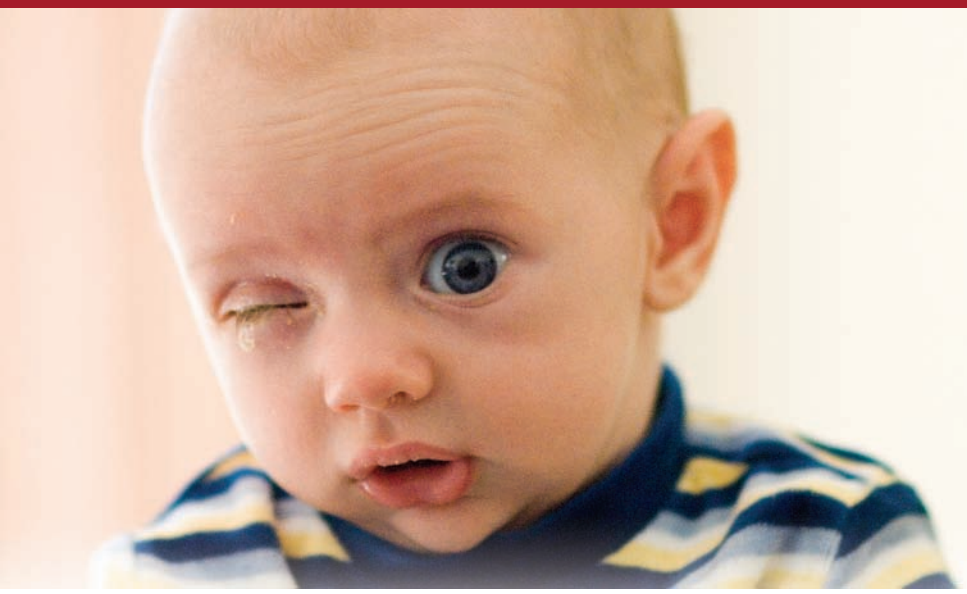
1. When compared with adults, why are infants and children at an increased risk of head trauma?
   a. The head of the infant and young child is large in proportion to the body and the neck muscles are not well developed.
   b. The development of the nervous system is complete at birth but remains immature.
   c. The spine is very immobile in infants and young children.
   d. The skull is more flexible due to the presence of sutures and fontanels.
2. At a well-child visit, hydrocephalus may be suspected in an infant if upon assessment the nurse finds:
   a. Narrow sutures
   b. Sunken fontanels
   c. A rapid increase in head circumference
   d. Increase in weight since last visit
3. A 10-year-old child is admitted to the hospital due to history of seizure activity. As his nurse, you are called into the room by his mother who states he is having a seizure. What would be the priority nursing intervention?
   a. Prevention of injury by removing the child from his bed
   b. Prevention of injury by placing a tongue blade in the child's mouth
   c. Prevention of injury by restraining the child
   d. Prevention of injury by placing the child on his side and opening his airway
4. A 6-month-old infant is admitted to the hospital with suspected bacterial meningitis. She is crying, irritable, and lying in the opisthotonic position. The priority nursing intervention would be:
   a. Educate the family on ways to prevent bacterial meningitis.
   b. Initiate appropriate isolation precautions and begin intravenous antibiotics.
   c. Assess the infant's fontanels.
   d. Encourage the mother to hold the infant and feed her.

Critical Thinking Exercises

1. A child is seen in the doctor's office after hitting his head while skateboarding. The child suffered no loss of consciousness, and has no external injuries and no significant past medical history. He is acting appropriately at this time. His only complaint is a dull headache. What instructions would you give the parents regarding his care at home? Include when they should seek further medical care.
2. A 10-year-old child is admitted to the pediatric unit after experiencing a seizure. A complete, accurate, and detailed history from a reliable source is essential. What information would you ask for while obtaining the history?
3. A 6-year-old child is admitted to the hospital because of a possible seizure. The child's mother calls the nurse to the room because the child is "jerking all over" and won't respond when she calls the child's name. List appropriate nursing interventions for this child. Prioritize the list of interventions.
4. Describe the impact of cerebral vascular accident in the child as compared with the adult. How does it affect the child's future? How will the nurse provide care differently for the child stroke victim as compared with the adult?

Study Activities

1. A 4-month-old child with a history of hydrocephalus has undergone surgery for placement of a VP shunt. What information would you include in the teaching plan?
2. Develop an example of a "headache log" that could be used by the family for chronicling the child's headaches, including triggers, relieving factors, and precipitating events. Ensure that the log is developed at a 6th-grade reading level to make it practical for low literacy parents.
3. In the clinical setting, interview the parent of a child who has suffered significant brain trauma or injury (such as head trauma, IVH, or stroke). Talk with the family about the types of care the child requires. Reflect upon this interview in your clinical journal, and compare how the ongoing care for this child compares with that for a typical child.



CHAPTER 38

Nursing Care of the Child With a Disorder of the Eyes or Ears

Enrique Baxter, a 9-month-old, is brought to the clinic by his mother. His mother tells you, "Enrique has been fussy and not eating or sleeping well for the past 2 days."

KEY TERMS

acuity
amblyopia
blindness
conductive hearing loss
deaf
decibel
hearing impairment
nystagmus
pressure-equalizing tubes (PE tubes)
ptosis
sensorineural hearing loss
strabismus
tympanometry
tympanostomy
vision impairment

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Differentiate between the anatomic and physiologic differences of the eyes and ears in children as compared with adults.
2. Identify various factors associated with disorders of the eyes and ears in infants and children.
3. Discuss common laboratory and other diagnostic tests useful in the diagnosis of disorders of the eyes and ears.
4. Discuss common medications and other treatments used for treatment and palliation of conditions affecting the eyes and ears.
5. Recognize risk factors associated with various disorders of the eyes and ears.
6. Distinguish between different disorders of the eyes and ears based on the signs and symptoms associated with them.
7. Discuss nursing interventions commonly used in regard to disorders of the eyes and ears.
8. Devise an individualized nursing care plan for the child with a sensory impairment or other disorder of the eyes or ears.
9. Develop patient/family teaching plans for the child with a disorder of the eyes or ears.
10. Describe the psychosocial impact of sensory impairments on children.

Wow

With the help of a nurse's care and healing, the child's senses provide him or her with an antenna to the universe.

Children commonly suffer from disorders related to the eyes and ears. Conjunctivitis and otitis media are two very common disorders in childhood. Other inflammatory and infectious conditions also affect the child's eyes or ears. Various alterations such as refractive error, strabismus, and amblyopia affect the development of visual acuity in children. Any alteration in the ear that contributes to hearing loss may have a significant impact on the child's language acquisition. It is important for nurses to be familiar with the most common disorders of the eyes and ears in order to provide appropriate care to these children and to encourage optimal development in all children. In addition, the nurse may be caring for a child with another problem who is also either visually or hearing impaired. The nurse must take these developmental differences into account when planning care for these children.

Variations in Pediatric Anatomy and Physiology

It is important for the nurse to understand the impact of eye and ear disorders on the child's development. Some children may be born with anomalies of the eyes or ears that will have a significant impact on vision and hearing, as well as psychomotor development. On the other hand, disorders affecting the eyes or ears, particularly if chronic or recurrent, can have a significant impact on the development of visual acuity or may cause hearing impairment.

Eyes

Light-skinned children are often born with blue eyes. The iris becomes pigmented over time and eye color is determined by 6 to 12 moths of age. The newborn's sclera may be slightly bluish-tinged but becomes white within weeks. The eyeball of the infant and young child occupies a relatively larger space within the orbit than the adult's does, making it more susceptible to injury (Fig. 38.1).

The spherical shape of the newborn's lens does not allow for distance accommodation, so the newborn sees best at a distance of about 8 to 10 inches. The optic nerve is not completely myelinated, so color discrimination is incomplete. Visual acuity develops over the first few years of the child's life. At birth, acuity ranges from 20/100 to 20/400. By age 2 to 3 years, the visual acuity of most children is 20/50, with 20/20 achieved by age 6 to 7 years. The rectus muscles are uncoordinated at birth and mature over time so that binocular vision (the ability to focus with both eyes simultaneously) may be achieved by 4 months of age. In the very preterm infant, retinal vascularization is incomplete, so visual acuity may be affected.

Ears

Congenital deformities of the ear are often associated with other body system anomalies and genetic syndromes. The presence of ear anomalies may lead to the search for and subsequent diagnosis of the other anomalies or syndromes. The infant's relatively short, wide, and horizontally placed eustachian tubes allow bacteria and viruses to gain access to the middle ear easily, resulting in increased numbers of ear infections as compared to the adult. As the child matures, the tubes assume a more slanted position, so older children and adults generally have fewer cases of middle ear effusion and infection (Fig. 38.2). Sometimes enlargement of the adenoids contributes to obstruction of the eustachian tubes, leading to infection.

Common Medical Treatments

A variety of interventions are used to treat disorders of the eyes and ears in children. The treatments listed in Common Medical Treatments 38.1 and Drug Guide 38.1 usually require a physician's order when a child is hospitalized.

Nursing Process Overview for the Child With a Disorder of the Eyes or Ears

Care of the child with a disorder of the eyes and ears includes assessment, nursing diagnosis, planning, interventions, and evaluation. There are a number of general concepts related to the nursing process that can be applied

Figure 38.1 The relatively larger space that the infant's and young child's eyeball occupies within the orbit makes it more susceptible to injury as compared with the adult's eye.

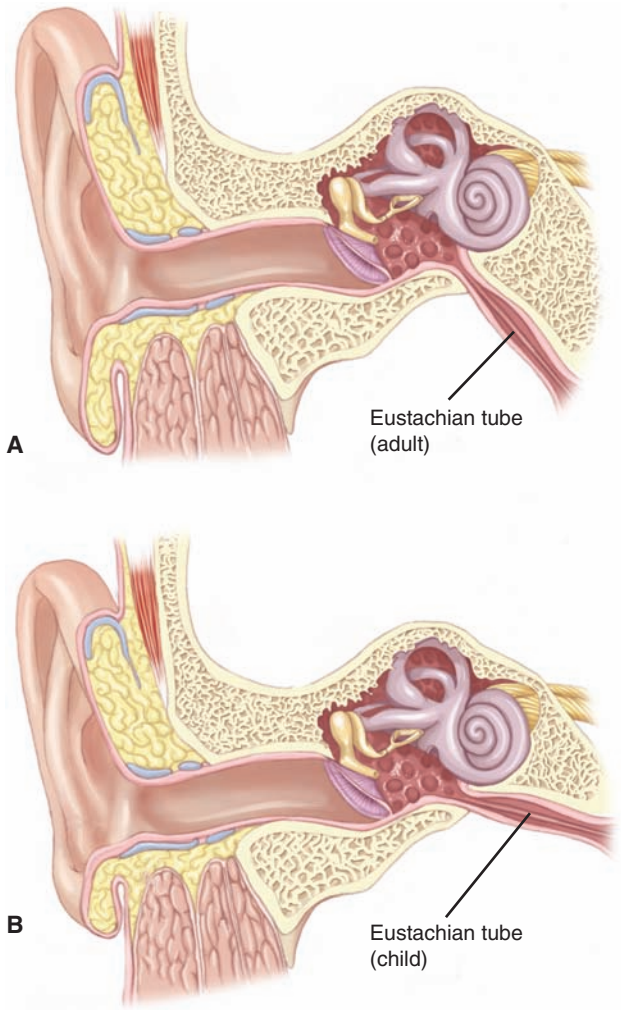


FIGURE 38.2 Note the child's relatively shorter, wider eustachian tubes and their horizontal positioning (**B**) as compared with the adult's (**A**).

to disorders of the eyes and ears. From a general understanding of the care involved for a child with alterations in the eyes or ears, the nurse can then individualize the care based on client specifics.

Assessment

Assessment of disorders of the eyes and ears in children includes health history, physical assessment, and laboratory or diagnostic testing.

Remember Enrique, the 9-month-old with fussiness and poor feeding who was not sleeping well? What additional health history and physical examination assessment information should you obtain?

Health History

The health history comprises past medical history, family history, history of present illness, as well as treatments used at home. The past medical history may be significant for prematurity, genetic defect, eye or ear deformities, visual acuity deficit or blindness, hearing impairment or deafness, recurrent ear infections, or ear surgeries. Family history might be significant for eye or ear deformities or vision or hearing impairment or may reveal contacts for infectious exposure.

When eliciting the history of the present illness, inquire about its onset and progression and the presence of fever, nasal congestion, eye or ear pain, eye rubbing, ear pulling, headache, lethargy, or behavioral changes. Document if the child has corrective lenses or hearing aids prescribed and to what extent these devices are actually used.

Physical Examination

When assessing the eyes and ears, begin with inspection and observation. Additionally, testing of visual activity and hearing may be performed.

Inspection and Observation

The physical examination should begin with inspection and observation. Note whether the child uses eyeglasses, corrective lenses, or a hearing aid. Observe the eyes: note their positioning and symmetry, presence of strabismus, nystagmus, and squinting. The eyelids should open equally (failure to open fully is termed **ptosis**). Note variations in eye slant and the presence of epicanthal folds. Assess the eyes for presence of eyelid edema, sclera color, discharge, tearing, and pupillary equality, as well as size and shape of the pupils. Evert the eyelid to inspect the palpebral conjunctivae for redness. Test for extraocular movements and pupillary light response and accommodation. Note symmetry of corneal light reflex. Note presence of red reflex with an ophthalmoscope. Perform an age-appropriate visual acuity test. Refer to Chapter 30 for more detailed information related to visual acuity testing.

▶ ***Take*** NOTE!

Attempts to inspect the palpebral conjunctivae may be frightening to children. Ask the older, cooperative child to evert the eyelid himself or herself, while the nurse inspects the conjunctivae.

▶ ***Take*** NOTE!

Though the sclerae are bluish in newborns, they become white in the first few weeks of life. Blue sclerae that persist beyond a few weeks of life may be an indicator of osteogenesis imperfecta type I, an inherited connective tissue disorder.

COMMON MEDICAL TREATMENTS 38.1

Treatment	Explanation	Indication	Nursing Implications
Warm compress	Warm, moist washcloth	Conjunctivitis	• Use very warm water from the tap (to avoid risk of burning, do not microwave).
Corrective lenses	In eyeglass form or as contact lenses	Correction of astigmatism, refractive error, strabismus	• Use a safety strap to help young children wear their eyeglasses.
Patching	An adhesive patch is applied to the healthier eye for several hours each day.	Strabismus, amblyopia, any other eye condition that results in one eye being weaker than the other	• Inform parents that though difficult to obtain, compliance with patching is critical. • A "pirate patch" may coax preschoolers into compliance.
Eye muscle surgery	Surgical alignment of the eyes	Strabismus	• Protect the operative site with patching. • Use elbow restraints if necessary.
Pressure-equalizing (PE) tubes (tympanostomy tubes)	Tiny plastic tubes inserted in the tympanic membrane	Chronic otitis media with effusion	• Teach parents "dry ears" precautions if prescribed or preferred by the surgeon.
Hearing aids	Amplification device worn in the ear	Hearing impairment	• Ensure appropriate fit and adequate amplification. • Direct families to outfitters that provide loaner aids of various brands and styles to determine best fit and amplification for the child.
Cochlear implants	Surgically inserted electronic prosthetic device	Sensorineural hearing loss	• Inform families that the usual minimum age for this procedure is 12 months.

Inspect the ears: note their size and shape, position, and the presence of skin tags, dimples, or other anomalies (Fig. 38.3). Upon otoscopic examination, note presence of cerumen, discharge, inflammation, or a foreign body in the ear canal. Visualize the tympanic membrane and observe its color, landmarks, and light reflex, as well as presence of perforation, scars, bulging, or retraction. Tympanic membrane mobility may be tested with pneumatic otoscopy. Auditory acuity is tested via the whisper test, audiometry, or other age-appropriate test (refer to

DRUG GUIDE 38.1 Common Drugs for Ear and Eye Disorders

Medication	Action	Indication	Nursing Implications
Antibiotics (oral, otic, ophthalmic)	Treatment of bacterial infections of the eyes and ears	Acute otitis media, otitis externa, conjunctivitis	Teach families to complete the entire course as prescribed. Check for drug allergies prior to administration.
Antihistamines	Block histamine reaction	Allergic conjunctivitis	Topical drops used. Oral agents usually prescribed if allergic rhinitis accompanies the conjunctivitis.
Analgesics	Pain relief	Otitis media, otitis externa, after eye or ear surgery	Narcotic analgesics may be necessary in some instances.

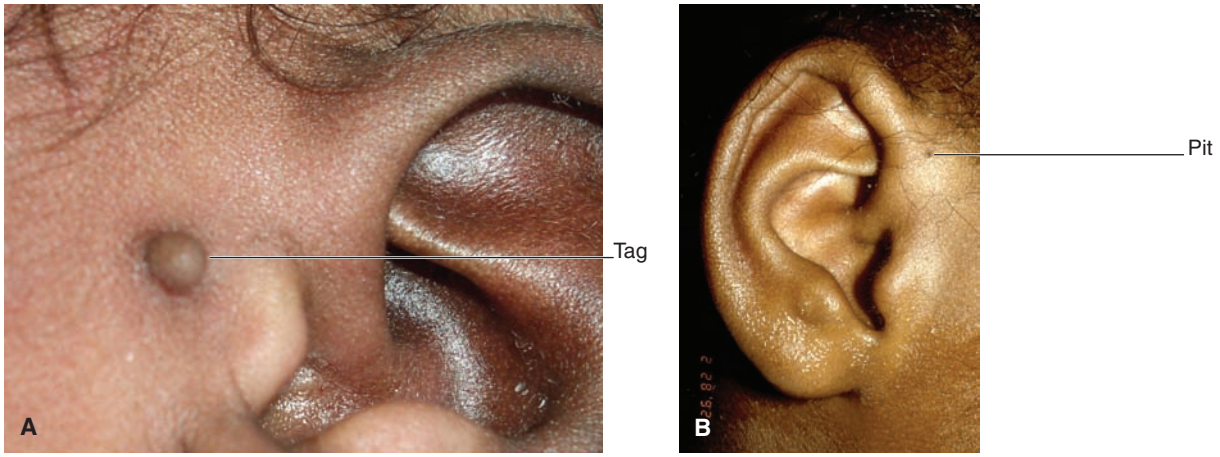

FIGURE 38.3 Note the skin tag (**A**) and preauricular pit (**B**) (in front of the ear).

Chapter 30 for a more detailed explanation of hearing testing).

Palpation

Usually, the eyes are not palpated. In the case of injury the upper eyelid may be everted for examination purposes. Palpate the ear for tenderness over the tragus or pinna. Note the presence of tenderness over the mastoid area (tenderness may be present when otitis media progresses to mastoiditis). Palpate for enlarged cervical lymph nodes (this occurs when the eyes or ears are infected).

Laboratory and Diagnostic Testing

The Common Laboratory and Diagnostic Tests display offers an explanation of the laboratory and diagnostic tests most commonly used for disorders of the eyes and ears. These tests can assist the physician in diagnosing the disorder and/or can be used as guidelines in determining ongoing treatment. Laboratory or non-nursing personnel obtain some of the tests, while the nurse may obtain others. In either instance the nurse should be familiar with how the tests are obtained, what they are used for, and normal versus abnormal results. This knowledge will also be necessary when providing patient and family education related to the testing.

Nursing Diagnoses and Related Interventions

Upon completion of a thorough assessment, the nurse might identify several nursing diagnoses, including:

- Disturbed sensory perception
- Risk for infection
- Pain
- Delayed growth and development
- Impaired verbal communication
- Deficient knowledge
- Interrupted family processes
- Risk for injury

COMMON LABORATORY AND DIAGNOSTIC TESTS 38.1

Test	Explanation	Indication	Nursing Implications
Culture of eye or ear discharge	Fluid draining from the eye or ear is cultured	To determine specific bacteria present and appropriate antibiotic coverage	Easy to collect, relatively pain-free. If drainage must be removed from within the ear canal, more likely to be painful.
Tympanic fluid culture	Culture of fluid aspirated from the middle ear	To determine specific bacteria present and appropriate antibiotic coverage	Painful; usually performed only by specially trained physicians.
Tympanometry	Probe in ear canal measures movement of the eardrum	Determines extent of effusion of the middle ear	Quick and easy to perform (seconds). Requires accurate-sized probe for adequate seal of the ear canal.

After completing an assessment of Enrique, the nurse noted the following: fever, tugging at his ears, and increased crying when lying down. Based on the assessment findings, what would your top three nursing diagnoses be for Enrique?

Nursing goals, interventions, and evaluation for the child with an eye or ear disorder are based on the nursing diagnoses. Nursing Care Plan 38.1 may be used as a guide in planning nursing care for the child with an eye or ear disorder, but it should be individualized based on the patient's symptoms and needs. Refer to Chapter 35 for the nursing care plan for pain management. Additional information will be included later in the chapter as it relates to specific disorders.

Based on your top three nursing diagnoses for Enrique, describe appropriate nursing interventions.

Infectious and Inflammatory Disorders of the Eyes

Infectious and inflammatory disorders of the eyes include conjunctivitis, nasolacrimal duct obstruction, eyelid lesions, and periorbital cellulitis.

CONJUNCTIVITIS

Inflammation of the bulbar or palpebral conjunctiva is referred to as conjunctivitis. It can be infectious, allergic, or chemical in nature. Viruses or bacteria may cause infectious conjunctivitis. Adenoviruses and influenza account for the bulk of cases of viral conjunctivitis. The most common bacterial cause is *Staphylococcus aureus,* but many cases are also caused by *Streptococcus pneumoniae, Haemophilus influenzae,* and other bacteria. In the newborn, *Chlamydia trachomatis* and *Neisseria gonorrhoeae* are more common causes. Infectious conjunctivitis is very contagious, so epidemics are common, particularly in young children. Risk factors for acute infectious conjunctivitis include age less than 2 weeks; daycare, preschool, or school attendance; concomitant viral upper respiratory infection; pharyngitis; or otitis media. Concurrent acute otitis media may occur depending upon the bacterial cause (Cook & Walsh, 2005). Complications from simple infectious conjunctivitis are uncommon. Neonates with chlamydial conjunctivitis may be at risk for the development of chlamydial pneumonia.

Allergic conjunctivitis results from exposure to particular allergens. Allergic conjunctivitis may be a seasonal or year-round complaint. A genetic predisposition to allergic conjunctivitis exists, just as it does for asthma, allergic rhinitis, and atopic dermatitis. Allergic conjunctivitis occurs more frequently in school-age children and adolescents than it does in infants and young children because of repeat exposure to allergens over time. In the case of seasonal allergic conjunctivitis, the severity of symptoms and the number of children affected are directly related to the pollen count in the area.

Therapeutic Management

Therapeutic management of conjunctivitis is prescribed depending upon the cause. Bacterial conjunctivitis is generally treated with an ophthalmic antibiotic preparation (drops or ointment). Viral conjunctivitis is a self-limiting disease and does not require topical medication. Eye drops with an antihistamine or mast cell stabilization effect may be helpful in alleviating symptoms of allergic conjunctivitis. If other allergy signs and symptoms are also present, an oral antihistamine may also be prescribed. Table 38.1 compares bacterial, viral, and allergic conjunctivitis.

Pathophysiology

When bacteria or viruses come in contact with the bulbar or palpebral conjunctiva, they are recognized as foreign antigens and an antigen–antibody immune reaction occurs, resulting in inflammation. Allergic conjunctivitis occurs through a different mechanism. Contact with the allergen results in an allergic response (overreaction of the immune response). The mast cell and histamine mediators are then activated, resulting in inflammation.

Nursing Assessment

Nursing assessment of the child with conjunctivitis, regardless of the cause, is similar. It includes health history, physical examination, and in rare instances laboratory testing.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Redness
- Edema
- Tearing
- Discharge
- Eye pain
- Itching of the eyes (usually with allergic conjunctivitis)

Determine the onset of symptoms and their progression as well as response to treatments used at home. Assess for risk factors for infectious conjunctivitis, such as daycare or school attendance. Note any history of an upper respiratory infection, sore throat, or earache. Question parents about possible infectious exposures. Review the health history for risk factors for allergic conjunctivitis such

Nursing Care Plan 38.1

OVERVIEW FOR THE CHILD WITH A DISORDER OF EYES OR EARS

NURSING DIAGNOSIS: Sensory perception, disturbed (visual) related to visual impairment or blindness as evidenced by lack of reaction to visual stimuli, squinting, holding items close

Outcome Identification and Evaluation

Child will reach maximal vision potential: *Child uses corrective lenses appropriately and is able to participate in play and schoolwork.*

Intervention: Improving Vision

- Encourage corrective lens use *for enhancement of vision.*
- For the severely impaired or blind child, identify yourself via voice and name items in environment for the child *so that the child is aware of his or her surroundings.*
- Support the family's efforts at vision therapy and other habilitation programs *to promote vision enhancement.*
- Engage the parents in bedside caregiving *because the parents' voice and presence are reassuring to the child.*

NURSING DIAGNOSIS: Sensory perception, disturbed (auditory) related to hearing loss as evidenced by lack of reaction to verbal stimuli, delayed attainment of language milestones

Outcome Identification and Evaluation

Child will reach maximal hearing and speech potential: *Child uses aids appropriately and communicates effectively.*

Intervention: Improving Hearing

- Assess hearing ability frequently *because early detection of hearing loss allows for earlier intervention and correction.*
- Assess language development at each visit *to allow for early detection of hearing loss (earlier intervention and correction).*
- Encourage hearing aid use *for amplification of sound.*
- Teach about hearing aid battery safety *to avoid aspiration of battery.*
- Assist child with focusing on sounds in the environment *to encourage listening skills.*
- Refer for and encourage attendance at communication habilitation program *to maximize communication potential.*

NURSING DIAGNOSIS: Risk for infection related to presence of infectious organisms as evidenced by fever, presence of virus or bacteria on laboratory screening.

Outcome Identification and Evaluation

Child will exhibit no signs of secondary infection and will not spread infection to others: *Symptoms of infection decrease over time, and others remain free from infection.*

Intervention: Reducing Infection Risk

- Maintain aseptic technique and practice good hand washing *to prevent introduction of further infectious agents.*
- Limit number of visitors, screening for recent illness, *to prevent further infection.*
- Administer antibiotics if prescribed *to prevent or treat bacterial infection.*
- Encourage nutritious diet according to child's preferences *to assist body's natural infection-fighting mechanisms.*
- Isolate the child as required *to prevent nosocomial spread of infection.*
- Teach child and family preventive measures such as good hand washing, covering mouth and nose when coughing or sneezing, adequate disposal of used tissues, *to prevent nosocomial or community spread of infection.*

(continued)

Nursing Care Plan 38.1 (continued)

NURSING DIAGNOSIS: Growth and development delay, related to sensory impairment as evidenced by delay in attainment of developmental milestones

Outcome Identification and Evaluation

Child will achieve optimum independence for age: *Child participates in age-appropriate developmental activities.*

Intervention: Encouraging Growth and Development

- Encourage attainment of developmental milestones with use of assistive devices as needed *for timely developmental achievements.*
- Foster independence in ADLs *to promote sense of accomplishment.*
- Encourage participation in play with another child or within a group *to promote socialization.*
- Assist family to set limits and apply discipline *because structure and routine provide a secure environment in which the developing child can grow.*
- Encourage friendships with other children with a sensory impairment *to promote socialization and let the child know that he or she is not the only one with these challenges.*

NURSING DIAGNOSIS: Impaired verbal communication related to hearing loss as evidenced by lack of or inarticulate speech, lack of alternate communication channel

Outcome Identification and Evaluation

The child will communicate effectively with the method chosen by the family (this may be sign language, oral/deaf speech, cued speech, or augmentative alternative communication device).

Intervention: Improving Communication

- Encourage choice of and attendance at communication habilitation program *to promote continued learning.*
- Provide consistency between home and hospital in regard to communication style/devices *to promote continued learning.*
- Support the child's efforts at correct speech *to promote speech development through reinforcement and praise.*
- Encourage family to use spoken language and read books at home *to continue to promote appropriate language development.*

NURSING DIAGNOSIS: Deficient knowledge related to sensory impairment (vision or hearing) as evidenced by new diagnosis and parents' questions

Outcome Identification and Evaluation

Parents express understanding of diagnosis and care of child: *Parents verbalize understanding, demonstrate use of assistive devices, or independently perform medical treatments.*

Intervention: Educating the Family

- Review diagnosis and plan of care with the parents *to promote understanding of the disease process.*
- Refer family to resources available for sensory impaired children *to provide further education and support to the parents.*
- Demonstrate medical treatments prescribed or use of assistive devices, requiring a return demonstration, *which shows the parents' ability to provide the prescribed care for the child.*
- Encourage exploration of different communication and learning modes available for the sensory impaired child *to allow the child and family to find the right educational and communication style fit.*

Nursing Care Plan 38.1 (continued)

NURSING DIAGNOSIS: Family processes, interrupted, related to child's sensory impairment as evidenced by parent verbalization, nonverbal communication, altered coping

Outcome Identification and Evaluation

Parents demonstrate adequate coping and decreased anxiety: *Parents are involved in child's care, ask appropriate questions, and are able to discuss child's care and condition calmly.*

Intervention: Encouraging Appropriate Family Interactions

- Encourage parents' verbalization of grief if child is hearing or vision impaired. *Parents must deal with their own feelings of loss to successfully care for the child with an impairment.*
- Encourage parents' verbalization of concerns related to child's illness. *This allows for identification of concerns and demonstrates to the family that the nurse also cares about them, not just the child.*
- Explain therapy, procedures, and child's behavior to parents; *developing an understanding of the child's current status helps decrease anxiety.*
- Encourage parental involvement in care *so that parents may continue to feel needed and valued.*

NURSING DIAGNOSIS: Risk for injury related to vision loss as evidenced by difficulty navigating surroundings

Outcome Identification and Evaluation

The infant or child will remain free from injury.

Intervention: Preventing Injury

- Orient the child to hospital surroundings *because awareness is the first step to preventing injury.*
- Encourage parent to be at bedside *so that the child feels more comfortable.*
- Encourage use of assistive devise *to promote safety.*

as a family history and a history of asthma, allergic rhinitis, or atopic dermatitis. Determine seasonality related to the symptoms and whether the symptoms occur after exposure to particular allergens, such as pollen, hay, or animals.

Physical Examination

Observe for eyelid swelling or redness. Inspect the conjunctivae for redness (Fig. 18.4). Note quantity, color, and consistency of discharge. Bacterial infections generally result in a thick, colored discharge, whereas a clear or white discharge is generally seen with viral conjunctivitis. Allergic conjunctivitis often results in a watery discharge, sometimes profuse, which is usually present bilaterally. Contact with an allergen rubbed into one of the eyes may result in unilateral symptoms. Observe the child for other signs of allergic or atopic disease, and document presence of runny nose or cough as well.

Laboratory and Diagnostic Tests

Cases of bacterial, viral, and allergic conjunctivitis are generally diagnosed based on history and clinical presentation. Cases of viral and allergic conjunctivitis do not warrant laboratory testing. If bacterial conjunctivitis is suspected, then a bacterial culture of the eye drainage may be performed to determine the exact causative organism, thus allowing the most appropriate antibiotic to be prescribed.

TABLE 38.1 TYPES OF CONJUNCTIVITIS

Type of Conjunctivitis	Conjunctivae	Discharge	Additional Findings	Eyelid Edema	Treatment
Bacterial	Inflamed	Purulent, mucoid	Mild pain	Occasional	Antibiotic drops or ointment
Viral	Inflamed	Watery, mucoid	Lymphadenopathy, photophobia, tearing	Usually present	Symptom relief; anti-herpetic agent if cause is herpes
Allergic	Inflamed	Watery or stringy	Itching	Usually present	Antihistamine and/or mast cell stabilizer drops

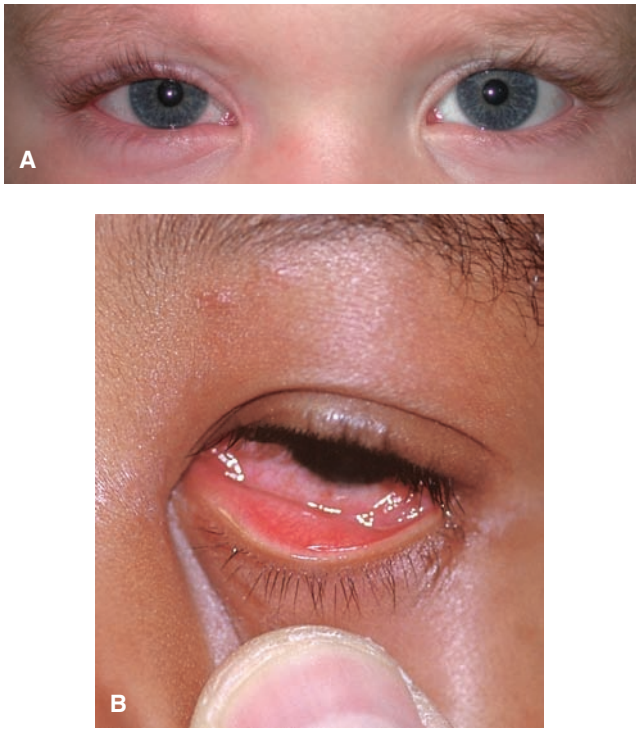

FIGURE 38.4 (**A**) Bacterial conjunctivitis: note redness of conjunctiva, and eyelid swelling. (**B**) Allergic conjunctivitis: note redness of conjunctiva, clear watery discharge.

Nursing Management

Nursing management of the various types of conjunctivitis focuses on alleviating symptoms and, for infectious causes, preventing spread.

Alleviating Symptoms

Teach parents how to apply eye drops or ointment (antibiotic for bacterial causes and antihistamine or mast cell stabilizer for allergic). Warm compresses may be used to help loosen the crust that accumulates on the eyelids overnight when drainage is copious, particularly with bacterial conjunctivitis.

The child with allergic conjunctivitis may experience perennial or seasonal allergies (or both). Encourage the child to avoid perennial allergens once the offending allergen is determined (refer to Chapter 39 for additional information related to education about perennial allergen avoidance). Seasonal allergies may include tree pollen in the winter or spring, grass pollen in the summer and ragweed, or flower pollen in the fall.

It is impossible to completely eliminate seasonal allergic responses, partly because it is important for children to participate in physical activity outdoors. Teach families to minimize seasonal allergens on the child's skin and hair. Educate families to:

- Encourage the child not to rub or touch the eyes.
- Rinse the child's eyelids periodically with a clean washcloth and cool water.
- When the child comes in from outdoors, wash the child's face and hands.
- Ensure that the child showers and shampoos before bedtime.

▶ *Take* NOTE!

The itching of allergic conjunctivitis may be relieved with cool compresses. An easy way to accomplish this is to have the child hold a tube of yogurt over the affected eye.

Preventing Infectious Spread

Because infectious conjunctivitis is extremely contagious, the parent must wash hands diligently after caring for the child. Teach parents and children about appropriate hand washing, and discourage them from sharing towels and washcloths. Children with viral conjunctivitis may return to school or daycare when symptoms lessen. When mucopurulent drainage is no longer present (usually after 24 to 48 hours of treatment with a topical antibiotic), the child with bacterial conjunctivitis may safely return to daycare or school (Brady, 2005).

▶ *Take* NOTE!

Avoid the use of vasoconstricting eye drops such as Visine to rid the eyes of redness. Rebound vasodilation may occur, and with it the redness returns. This leads to repeated frequent use of the drops to keep the eyes from being red but does not treat the actual cause of the redness.

▶ *Consider* THIS!

Bryn Carle, a 6-year-old, is brought to the clinic by her mother. She presents with redness of the left eye, edema, and drainage. What other assessment information would be helpful? Based on the history and clinical presentation, Bryn is diagnosed with conjunctivitis. What education will be necessary for the family to assist in alleviating symptoms and preventing infectious spread?

NASOLACRIMAL DUCT OBSTRUCTION

Stenosis or simple obstruction of the nasolacrimal duct is a common disorder of infancy, occurring in about 6% to 20% of the general population (Casady et al., 2006). It is unilateral in about 65% of cases. Chronic tearing occurs

and build-up in the lacrimal sac causes a mucoid or mucopurulent drainage. Over 90% of all cases resolve spontaneously by 1 year of age (American Association for Pediatric Ophthalmology and Strabismus, 2005). No apparent risk factors exist for the development of nasolacrimal duct obstruction or stenosis. Therapeutic management involves a "wait-and-see" approach. Massage may be prescribed, and if secondary bacterial infection is suspected or confirmed, antibiotic ointment or drops may be ordered. If the obstruction does not resolve by 12 months of age, then the pediatric ophthalmologist may probe the duct to relieve the obstruction (a brief outpatient procedure).

Nursing Assessment

Tearing or discharge from one or both eyes is often first noted at the 2-week checkup. Obtain a thorough history about the eye drainage to distinguish it from neonatal conjunctivitis. Determine the onset and progression of symptoms, as well as the newborn's response to any interventions attempted so far. Upon physical examination, note redness of the lower lid of the affected eye. If drainage is present, note its consistency, color, and quantity. Nasolacrimal duct obstruction is usually a diagnosis based upon clinical presentation, but culture of the eye drainage may be used to rule out conjunctivitis or secondary bacterial infection (Fig. 38.5).

Nursing Management

As previously stated, the majority of cases of nasolacrimal duct stenosis resolve spontaneously by 12 months of age. Nevertheless, the continual tearing and discharge is quite upsetting to the parents. Teach parents to clean the eye area frequently with a moist cloth. In addition, teach parents to massage the nasolacrimal duct, which may change the pressure and cause it to open, allowing drainage to occur. Refer to Teaching Guidelines 38.1 for appropriate nasolacrimal duct massage technique. Ensure that parents are educated about when and how to administer antibiotic eye drops if ordered.

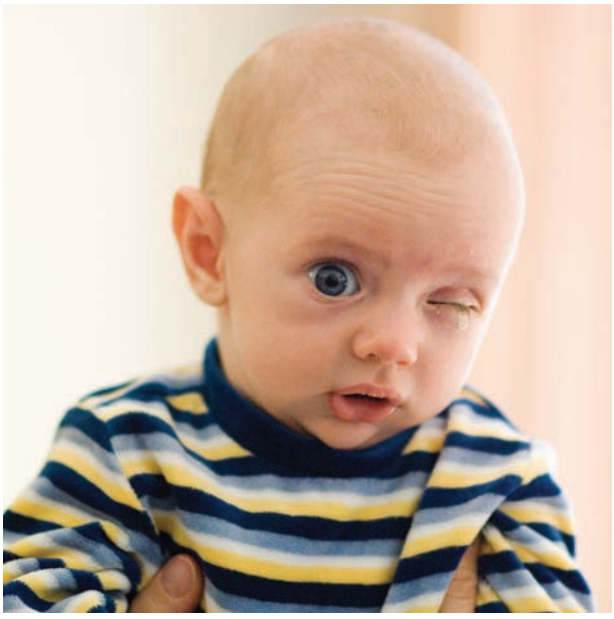

FIGURE 38.5 Mild eyelid redness and tearing are present in the infant with nasolacrimal duct stenosis. Note the presence of obstruction.

EYELID DISORDERS

Disorders of the eyelid include hordeolum (stye), chalazion, and blepharitis. Hordeolum is a localized infection of the sebaceous gland of the eyelid follicle, usually caused by bacterial invasion. Chalazion is a chronic painless infection of the meibomian gland. Blepharitis refers to chronic scaling and discharge along the eyelid margin. Chalazion may resolve spontaneously. Therapeutic management of hordeolum and blepharitis usually involves the use of antibiotic ointment.

Nursing Assessment

Determine the child's health history, noting onset of symptoms, extent and character of eye discharge, and presence of pain (hordeolum is usually painful). Inspect the eyelids, noting redness along the eyelid margin and presence of eyelid edema (hordeolum, blepharitis). Hordeolum may also be quite visible as an enlarged lesion along the lid margin, with purulent drainage present (Fig. 38.6). Chalazion may be visible as a small nodule on the lid margin. The conjunctivae remain clear with all three of these disorders.

Nursing Management

For hordeolum and blepharitis, instruct parents in the administration of antibiotic ointment. Encourage the use of hot, moist compresses. Inform parents that the stye may require several weeks to resolve completely. Also inform parents that chalazion will usually resolve spontaneously; if it does not, it may require minor surgical drainage.

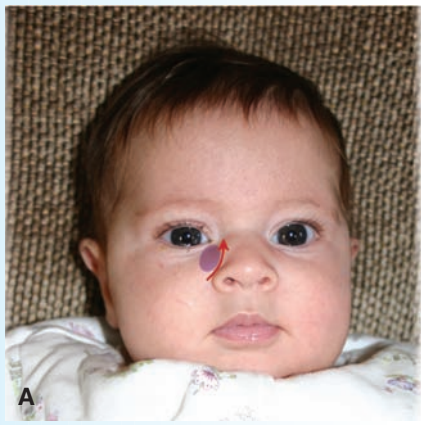
PERIORBITAL CELLULITIS

Periorbital cellulitis is a bacterial infection of the eyelids and tissue surrounding the eye. The bacteria may gain entry to the skin via an abrasion, laceration, insect bite, foreign body, or impetiginous lesion. Periorbital cellulitis may also result from a nearby bacterial infection, such as sinusitis. *Staphylococcus aureus, Streptococcus pyogenes,* and

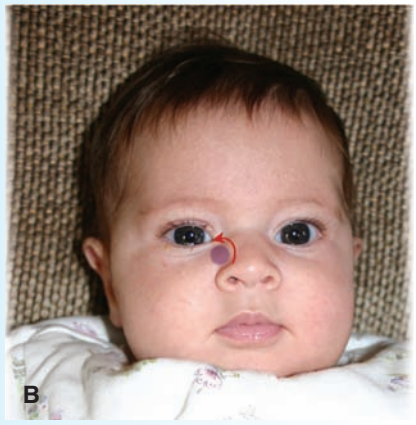
TEACHING GUIDELINES 38.1

Nasolacrimal Duct Massage

- Using the forefinger or little finger, push on top of the bone (the puncta must be blocked).



- Gently push in and up.



- Then gently push downward along the side of the nose.

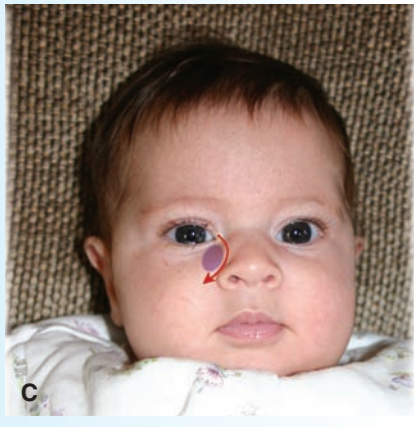


FIGURE 38.6 Hordeolum.

Streptococcus pneumoniae are the most commonly implicated bacteria. The bacteria produce either an enzyme or endotoxins that initiate the inflammatory response. Redness, swelling, and infiltration of the skin by the inflammatory mediators occur.

Therapeutic management of periorbital cellulitis focuses on intravenous antibiotic administration during the acute phase followed by completion of the course with oral antibiotics. Complications of periorbital cellulitis include bacteremia and progression to orbital cellulitis, which is a more extensive infection involving the orbit of the eye.

Nursing Assessment

Note the onset and duration of symptoms, as well as any treatment used so far. Document any history of fever. The child may complain of pain around the eye as well as restricted movement of the eye area. Inspect the eye, noting marked eyelid edema as well as a purplish or red color of the eyelid (Fig. 38.7). Usually the conjunctivae are clear and no discharge is present. If the extent of the edema allows the child to open the eye, assess visual acuity, which should be normal.

FIGURE 38.7 Periorbital cellulitis.

▶ **Take** NOTE!

Notify the physician immediately if any of these signs of progression to orbital cellulitis occur: conjunctival redness, change in vision, pain with eye movement, eye muscle weakness or paralysis, or proptosis.

Nursing Management

Apply warm soaks to the eye area for 20 minutes every 2 to 4 hours. Administer intravenous antibiotics as prescribed. Teach families the importance of completing the entire course of oral antibiotic treatment at home. Instruct parents to call the physician or have the child evaluated again if:

- The child is not improving.
- The child reports inability to move the eye.
- Visual acuity changes.
- Proptosis occurs.

Eye Injuries

As mentioned earlier, infants and young children are more susceptible to eye injuries than adults since the eyeball is relatively larger in relation to the space within the orbit. Developmental maturity may also play a part in eye injuries. For example, as infants and toddlers learn to walk and run, they do not have the awareness and maturity to avert disaster. Older children involved in sports and school science experiments are also at risk for eye injuries. A few of the more common eye injuries are eyelid injuries, contusion, scleral hemorrhage, corneal abrasion, a foreign body in the eye, and chemical injury.

Therapeutic management depends on the type of injury. Eyelid lacerations may require suturing. Deep lacerations may result in ptosis at a later date, so these patients should be referred to an ophthalmologist. Simple contusions (black eye) usually need only observation, ice, and analgesics. Scleral hemorrhages resolve gradually without intervention over a few weeks. Corneal abrasions may be allowed to self-heal, or antibiotic ointment may be prescribed. Foreign bodies in the eye require removal to prevent further irritation or abrasion. Chemical injuries require irrigation and vision evaluation.

Nursing Assessment

When a child presents with an eye injury, it is very important to obtain an accurate history related to the injury, followed by a focused physical examination, which consists mostly of inspection and observation. The nurse must determine whether an eye injury is non-emergent or emergent in order to provide rapid and appropriate treatment in the case of an emergency so that vision may be preserved.

Health History

Obtain an accurate history. Determine the mechanism of injury and obtain as much detail about the injury as possible. Questions that should be asked during the health history include:

- When did the injury occur?
- What exactly happened?
- Was an object involved? If so, what type of object, and how fast was it going?
- Was it a splash injury?
- Was the child wearing eye protective gear or eyeglasses when the injury occurred?

Determine the extent of pain if present. Document photosensitivity, sensation of a foreign body in the eye, and blurry or lost vision. Inquire about past medical history, including previous eye injury or surgery or vision problems. Determine the child's immunization status.

Physical Examination

Regardless of the type of eye injury, the examination of the child's eye can be quite difficult. The nurse plays an important role in assisting the child and family to cope with the examination. Children with an eye injury often are in acute pain. The area surrounding the eye swells quickly after blunt trauma. The edema and tearing make the eye examination more difficult. Children are very frightened because of the pain and difficulty seeing. Approach the child in a calm and gentle manner. Soothe and coax the child as the eye is examined. Younger children may need to be restrained briefly in order for the examination to proceed safely.

Note the eyelid placement and look for signs of trauma such as bleeding, edema, and eyelid malformation. Evaluate the child's ability to open the eyes. Use a penlight to evaluate the pupils' response to light and accommodation (in the case of non-emergent eye trauma, the pupils should remain equally round and reactive to light and accommodation [PERRLA]). Note redness or irritation of the sclerae and/or conjunctivae. Observe for excessive tearing. Figure 38.8 shows appropriate technique for eversion and examination of the interior of the eyelid.

In a non-emergent situation, evaluate visual acuity via the use of an age-appropriate vision screening tool (refer to Chapter 30 for additional information related to visual acuity screening). Generally, radiologic testing is used only in emergency situations. Table 38.2 provides assessment information specific to eyelid laceration, simple contusion, scleral hemorrhage, corneal abrasion, and foreign body in the eye.

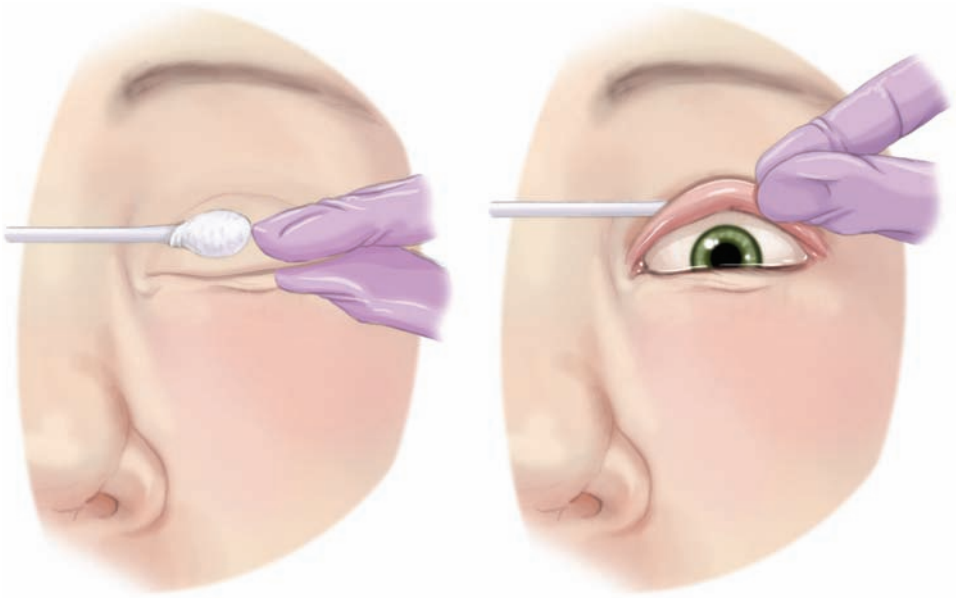

FIGURE 38.8 Eversion of the eyelid for examination. Place a cotton-tipped applicator over the eyelid. Pull the eyelid outward and up over the applicator.

▶ *Take NOTE!*

If pupillary reaction is abnormal, vision is affected (decreased acuity from the child's norm, diplopia, or blurriness), or extraocular movements are affected, the child should be immediately referred to an ophthalmologist for further evaluation.

Nursing Management

Children with urgent or emergent conditions must be referred to an ophthalmologist immediately to preserve vision. Urgent and emergent conditions include:

- Traumatic hyphema
- Blowout fracture
- Ruptured globe

TABLE 38.2 Assessment of Eye Injuries

Description of Injury	Nursing Assessment
Eyelid Injuries: May occur as laceration to the eyelid	• Laceration is noted at any point along the lid • Vision is unaffected
Simple Contusion (Black Eye): Occurs as a result of blunt trauma to the eye area	• Bruising and edema of lids or area surrounding eye • PERRLA • Extraocular movements intact • Visual acuity intact • No diplopia or blurred vision • Pain surrounding eye but not within the eye
Scleral Hemorrhage: Caused by blunt trauma or increased pressure such as with coughing	• Painless • Appears as erythema in the sclera; can be quite large initially • Vision unaffected
Corneal Abrasion: Results from foreign body such as sand, grit, or other small object scratching the cornea	• May have tearing • Eye pain • PERRLA • Vision may be blurry • Photophobia may be present
Foreign Body: May be dirt, glass, or other small particle	• Tearing • Complaint of "something in the eye" • PERRLA • Vision may be blurry

- Thermal injury/corneal flash burn
- Extensive animal bite
- Lid laceration with underlying structural involvement
- Corneal abrasion in which corneal penetration is suspected
- Foreign body embedded in the globe

Managing Non-emergent Eye Injuries

Non-emergent eye injuries usually need only simple management. Assist the physician with positioning and distraction of the child for eyelid laceration suturing. The child may require sedation or pain medication for this procedure.

To decrease edema in the child with a black eye (simple contusion), instruct the parent to apply an ice pack to the area for 20 minutes, then remove it for 20 minutes, and continue to repeat the cycle. Tell the parents and child that bruising of the surrounding eye area may take up to 3 weeks to resolve.

The appearance of a scleral hemorrhage may be frightening. Instruct the parents and child about the benign nature of the hemorrhage and its natural history of resolution without intervention over a period of a few weeks.

If the child with a corneal abrasion has pain, analgesics may be helpful. Tell parents that most corneal abrasions heal on their own. If an antibiotic ointment is prescribed, instruct the parents in appropriate administration of the ointment.

▶ *Take* NOTE!

Patching of the eye with a corneal abrasion is no longer recommended, as children are often able to open the eye under the patch, which causes drying of the eye and further irritation, possibly contributing to prolonged recovery from the abrasion.

Foreign bodies may be removed from the eye by gently everting the eyelid and wiping the foreign body away with a sterile cotton-tipped applicator. Irrigation with normal saline may also wash the foreign body away.

For chemical injury, irrigate the eye with copious amounts of water. Consult ophthalmology for further evaluation and management.

▶ *Take* NOTE!

Refer the child with a large foreign body in the eye or one that is imbedded in the globe of the eye to the ophthalmologist for appropriate, safe removal.

Eye injuries can be prevented, and nurses play a vital role in educating the public about prevention of eye injuries and use of appropriate safety equipment. See Healthy People 2010 and Evidence-Based Practice 38.1.

Visual Disorders

Adequate visual development requires appropriate sensory stimulation to both eyes over the first few years of life. When one or both eyes are deprived of this stimulation, visual development does not progress appropriately, and visual impairment or blindness may result. This may occur when the eyes are not aligned properly, visual acuity between the eyes is disparate, or other problems with the eyes exist. If vision disorders are diagnosed at an early age and treatment is begun, then vision may progress normally. However, when these disorders go untreated, the young child's developing vision may be significantly reduced. Children must be appropriately screened for these disorders.

Common visual disorders in childhood include refractive errors, astigmatism, strabismus, amblyopia, nystagmus, glaucoma, and cataracts.

REFRACTIVE ERRORS

The most common cause of visual difficulties in children is refractive errors. When the light that enters the lens does not bend appropriately to allow it to fall directly on the retina, then a refractive error occurs. Young children naturally have hyperopia (farsightedness) because the depth of the eye globe is not fully developed until about age 5 years. These children may have blurriness at close range, but by school age this blurriness usually resolves.

HEALTHY PEOPLE 2010

Objective	Significance
(Developmental) Increase the proportion of public and private schools that require use of appropriate head, face, eye, and mouth protection for students participating in school-sponsored physical activities; increase the use of appropriate personal protective eyewear in recreational activities and hazardous situations around the home	• Educate the family about appropriate use of eye protective equipment during sports, lawn care, chemical use, and other potentially hazardous activities. • Encourage families to provide appropriate supervision of children (particularly young children) to reduce the risk of injury. • Educate families to teach their children safe practices in and around the home (not running with scissors, etc.).

EVIDENCE-BASED PRACTICE 38.1
The Effect of Patching for Corneal Abrasion on Healing and Decreased Pain

● Study
Simple corneal abrasions are a common eye complaint. Eye patching with or without antibiotic ointment has often been used despite a lack of evidence for its use. Additionally, patches are difficult to keep on young children and may be associated with corneal erosion. The authors included quasi-randomized and randomized studies evaluating patching versus no patching for treatment of simple corneal abrasion. Eleven trials with a total of 1014 participants were included in the review.

▲ Findings
The authors found that patching for simple corneal abrasions did not improve healing on day 1, nor did it decrease the amount of pain experienced. Additionally, binocular vision is lost when one eye is patched. Based on these results, it is not recommended that patching be used for treatment of simple corneal abrasions.

■ Nursing Implications
Parents worry significantly when their child experiences even a very mild eye injury. Teach parents about the ability of the cornea to heal quickly from a minor abrasion. Emphasize that non-patched corneal abrasions have been shown to heal more rapidly than those that are patched.

Turner, A. & Rabiu, M. (2007). Patching for corneal abrasion. *The Cochrane Library 2007, 4.*

When the light entering the eye focuses in front of the retina, it results in myopia (nearsightedness). Children who are nearsighted may see well at close range but have difficulty focusing well on the blackboard or other objects at a distance.

The treatment for both hyperopia and myopia is prescription eyeglasses or contact lenses. Generally, a child 12 years of age can demonstrate the responsibility necessary to wear and care for contact lenses. Contact lenses may be used in younger children but are lost or damaged more readily. Because of the continuing refractive development in the child's vision through adolescence, laser surgery for vision correction is not recommended by the American Academy of Ophthalmology until 18 years of age, though it may be done experimentally in some children (AAO, 2007).

Nursing Assessment

Elicit the health history, noting blurred vision, complaints of eye fatigue with reading, or complaints of eye strain (headache, pulling sensation, or eye burning). Note complaints of difficulty concentrating on or maintaining a clear focus on objects up close, avoidance of up-close work, or poor work performance (hyperopia). Note the risk factor of family history of myopia. Observe for squinting when the child looks at objects at a distance. Observe the hyperopic child for the presence of esotropia. Readily observable physical findings are not noted in the myopic child. Test visual acuity using an age-appropriate screening tool (for more information related to visual acuity screening, refer to Chapter 30). Hyperopia is usually not identified with visual acuity screening alone; it usually requires a retinal examination by an ophthalmologist.

Nursing Management

Nursing management of the child with a refractive error focuses on providing education about corrective lens use and monitoring for the need for new eyeglasses or contact lenses.

Educating About Eyeglass Use

Children may or may not be compliant with wearing eyeglasses. Glasses still carry a stigma, and the child may be teased or bullied. However, many children enjoy the improved vision they achieve when wearing their eyeglasses, and this can help them overcome the teasing they might suffer. Encourage the child with newly prescribed eyeglasses to wear them by having the parent spend "special time" with the child doing an activity that requires the glasses (such as reading or drawing). Teach the parent and child to remove eyeglasses with both hands and to lay them on their side (not directly on the lens on any surface). Instruct the child and family about cleaning the glasses daily with mild soap and water or a commercial cleansing agent provided by the optometrist. Use a soft cloth to clean the glasses, not paper towels, tissues, or toilet paper.

Educating About Contact Lens Use

Teach the older child or adolescent how to care for the contact lenses properly, including lens hygiene and lens insertion and removal. Inform the child and parents that protective eyewear should be worn when the child is participating in contact sports. If the eye becomes inflamed, remove the contact lens and wear eyeglasses until the eye is improved. Consult with the child's eye care provider to determine if medications prescribed for an eye problem can be used while the contact lens is in.

Monitoring for Fit and Visual Correction

Encourage the family to complete visual assessments as scheduled. Since the child's vision is continuing to develop and refraction is not stable, the corrective lens prescription may change more frequently than it does in an adult. As the young child in particular is continuing to grow at a rapid rate, the head size is also changing. Eyeglass frames may hurt or pinch the child as the child's head becomes larger. Teach families to check the fit of the glasses monthly. Monitor for signs of ill fit, such as constant removal of the glasses in an older child or rubbing at the glasses or eyes in the very young child. Monitor for squinting, eye fatigue or strain, and complaints of headache or dizziness, which may indicate the need for a change in the lens prescription. See Healthy People 2010.

ASTIGMATISM

In astigmatism the cornea's curvature is uneven, which results in an irregular quality of vision because the light rays are refracted unevenly. Sometimes the lens is irregularly shaped, having the same result.

Nursing Assessment

Explore the health history for symptoms of astigmatism. Children with astigmatism often have blurry vision and difficulty seeing letters as a whole, so their ability to read is affected. They may have headaches or dizziness. Older children may complain of eye fatigue or strain. Children with astigmatism often learn to tilt their heads slightly so that they can focus more effectively. This may lead to "normal" vision screenings, but the headache and dizziness still warrant further examination by an eye specialist. The diagnosis of astigmatism requires not only a visual acuity test but also a refractive error evaluation by an optometrist or ophthalmologist.

HEALTHY PEOPLE 2010

Objective	Significance
(Developmental) Reduce uncorrected visual impairment due to refractive errors; reduce blindness and visual impairment in children and adolescents aged 17 years and under	• Ensure that visual acuity testing begins with an age-appropriate screening tool by 3 years of age and continues yearly throughout childhood and adolescence. • Refer for an eye evaluation any children with complaints of difficulty seeing the front of the classroom or complaints of eye strain or difficulty with close work. • Screen infants and children for asymmetric corneal light reflex for early detection of amblyopia.

Nursing Management

Corrective lenses can help to, in effect, smooth out the curvature of the cornea, making the light ray refraction occur smoothly. As with refractive errors, encourage the child who requires corrective lenses for astigmatism to wear the eyeglasses or contact lenses regularly.

STRABISMUS

Strabismus refers to misalignment of the eyes. It is common and occurs in about 4% of children (Optometrists Network, 2006). The most common types of strabismus are exotropia and esotropia. In exotropia the eyes turn outward; in esotropia they turn inward. Because of this unequal alignment, visual development in each eye may proceed at different rates. Diplopia (double vision) may result, so vision in one eye may be "turned off" by the brain to avoid diplopia. Many infants have strabismus intermittently, but this usually resolves by 3 months of age. Intermittent strabismus that persists past 3 months of age or constant strabismus at any age warrants referral to an ophthalmologist for further evaluation.

Therapeutic management of strabismus may include patching of the stronger eye or eye muscle surgery. Corrective lenses are also used for strabismus. Complications of strabismus include amblyopia and visual deficits.

Nursing Assessment

Parents may be the first persons to notice that the child's eyes do not face in the same direction. Question parents about the onset of the problem and whether it is continuous or intermittent. If intermittent, does it occur more often when the child is tired? Elicit the health history, noting complaints of blurred vision, tired eyes, squinting or closing one eye in bright sunlight, tilting the head to focus on an object, or a history of bumping into objects (depth perception may be limited).

Observe the child's eyes for obvious exotropia or esotropia. In the absence of an obvious finding, assessment of the symmetry of the corneal light reflex is extremely helpful (Fig. 38.9). The "cover test" is also a useful tool for the identification of strabismus.

True strabismus should not be confused with pseudostrabismus. In pseudostrabismus, the eyes may appear slightly crossed (as in the child with wide nasal bridge and epicanthal folds), but the corneal light reflex remains symmetric.

FIGURE 38.9 Esotropia. Test for strabismus by observing symmetry of the corneal light reflex. The reflex falls to the left of one pupil and to the right of the other.

Nursing Management

It is extremely important to treat strabismus appropriately in the developing years so that equal visual acuity may be achieved in both eyes. When patching is prescribed, encourage the family to comply with this modality. Encourage eyeglass wearing if prescribed. Provide appropriate postoperative care by protecting the operative site with eye patching.

AMBLYOPIA

Amblyopia refers to poor visual development in the otherwise structurally normal eye. It develops within the first decade of life and if untreated, causes more cases of vision loss than all other conditions together in persons younger than 40 years of age. It occurs in about 2% to 3% of children (Dubowy, 2005). The vision in one eye is reduced because the eye and the brain are not working together properly. While the eyes are fighting to focus differently because of their differences in visual acuity, one eye is stronger than the other. This is why amblyopia is often referred to as "lazy eye."

Amblyopia may be caused by any disorder that affects normal visual development, including strabismus and differences in visual acuity or astigmatism between the two eyes. It may also result from eye trauma, ptosis, or cataract. Children with amblyopia, if untreated, will have worsening of the poorer eye and strain in the better eye, which may also lead to worsening of acuity in that eye. Eventually blindness will result in one or both eyes.

Therapeutic management of amblyopia focuses on strengthening the weaker eye. This may be achieved through patching for several hours per day, using atropine drops in the better eye (once daily), vision therapy, or eye muscle surgery if the cause is strabismus.

Nursing Assessment

One of the most important functions of the nurse is to identify on screening the preschool child with amblyopia. Begin visual acuity testing using an age-appropriate tool by 3 years of age. Observe for asymmetry of the corneal light reflex in the child of any age. This may be the only sign in the preverbal child.

Nursing Management

It is very important for children with amblyopia to receive appropriate treatment during the early years of visual development. Patching the better eye for several hours each day encourages the eye with poorer vision to be used appropriately and promotes visual development in that eye. The once-daily use of atropine drops in the better eye results in blurring in that eye, similarly encouraging use and development of the weaker eye. Support and encourage children and parents to comply with the patching protocol or atropine drop use.

Promoting eye safety is extremely important for the child with amblyopia; if the better eye suffers a serious injury, both eyes may become blind.

NYSTAGMUS

Nystagmus refers to a very rapid, irregular eye movement. It is described by some as "bouncing" of the eyes. It may occur in children with congenital cataracts, but the most common cause is a neurologic problem. It is difficult for the brain and eyes to communicate when the eyes are in continuous motion; thus, visual development may be affected. Children with nystagmus must receive further evaluation by an ophthalmologist and possibly a neurologist.

INFANTILE GLAUCOMA

Infantile glaucoma is an autosomal recessive disorder that is more common in interrelated marriages or relationships. It is often associated with other genetic disorders. It occurs in about 1 of 10,000 live births (Lighthouse International, 2007). Infantile glaucoma is characterized by obstruction of aqueous humor flow and increased intraocular pressure that results in large, prominent eyes. Vision loss may occur as a result of corneal scarring, optic nerve damage, or, most commonly, amblyopia.

Unlike adult glaucoma, in which medical management is the first step, therapeutic management of infantile glaucoma is focused on surgical intervention. Infantile glaucoma is treated surgically via goniotomy (removal of obstruction of the aqueous humor). Laser surgery is being used as well. Sometimes several surgeries may be necessary to correct the problem. Ongoing medication therapy may also be required.

Nursing Assessment

Note any family history of infantile glaucoma or other genetic disorders. Elicit the health history, noting history

of the infant keeping the eyes closed most of the time or rubbing the eyes. Observe the eye for corneal enlargement and clouding; the eye may appear enlarged. Photophobia may occur, so bright light may bother the infant. Tearing or conjunctivitis and eyelid squeezing or spasm may also occur. The pediatric ophthalmologist may use a tonometer to measure the intraocular pressure during the diagnostic phase.

Nursing Management

The main goal of nursing care for the infant with glaucoma is postoperative care. Family education will also be important.

Providing Postoperative Care

Postoperatively the eye will be patched and the child should be maintained on bed rest. Nursing care focuses on protection of the surgical site. Infants and toddlers may require elbow restraints to prevent them from rubbing the affected eye. These children may be quite anxious with one or both eyes patched, since their ability to see will be affected. Use a calm and soothing approach with these children, as well as distraction and developmentally appropriate play activities.

Educating the Family

Instruct parents and children to make sure the child avoids roughhousing and contact sports for at least 2 weeks after surgery. Before the first surgery occurs, prepare parents for the possibility that three or four operations may be necessary. Teach families how to administer postoperative medications. Encourage parents to comply with ongoing recommended visual assessments.

CONGENITAL CATARACT

A congenital cataract is an opacity of the lens of the eye that is present at birth. Sensory amblyopia will result if the infant goes untreated. Complications include visual developmental delay related to amblyopia. In children younger than 5 years of age, congenital cataract causes 16% of the cases of legal blindness (Lighthouse International, 2007). Bilateral cataracts may be associated with metabolic or genetic syndromes. Surgery to remove the opaque lens can be done as early as 2 weeks of age. The infant is then fitted with a contact lens. Intraocular lens implants are also being used (Watkinson & Graham, 2005). The best visual outcomes occur when cataracts are removed prior to 3 months of age. Glaucoma may occur as a complication after cataract surgery.

Nursing Assessment

Note history of lack of visual awareness. Observe the eyes for apparent cloudiness of the cornea (not always visible).

HEALTHY PEOPLE 2010

Objective	Significance
(Developmental) Reduce visual impairment due to glaucoma (Developmental) Reduce visual impairment due to cataract	• Appropriately screen infants and children for glaucoma or cataract. • Refer suspected cases to a pediatric ophthalmologist for further evaluation.

Upon ophthalmoscopic examination, the red reflex will not be observed in the affected eye.

Nursing Management

Postoperative care focuses on protecting the operative site and providing developmentally appropriate activities. Ensure that the protective eye patch is secure. Elbow restraints may be necessary in the older infant to prevent accidental injury to the operative site. Teach families how to administer antibiotic or corticosteroid ophthalmic drops if prescribed for postoperative use. Once the surgical site is healed, the "good" eye may be patched for several hours a day to promote visual development in the eye with the contact or intraocular lens. Regular visual assessments are critical for determining the adequacy of visual development after cataract removal. Instruct parents about the importance of using sunglasses that block ultraviolet rays in the child who has had a lens removed.

Retinopathy of Prematurity

Retinopathy of prematurity (ROP) is a disorder characterized by rapid growth of retinal blood vessels in the premature infant. In the fetus, retinal vascularization begins at 4 months and progresses until completion at 9 months or shortly after birth. The premature infant is born with incomplete retinal vascularization, yet new vessels continue to grow between the vascularized and nonvascularized retina. Risk factors include low birthweight, early gestational age, sepsis, high light intensity, and hypothermia. Changes in oxygen tension resulting from hypoxia, oxyhemoglobin dissociation curve changes that occur when adult blood is transfused to the premature infant, and the duration/concentration of supplemental oxygen are thought to play an important role in the development of ROP.

Premature infants should have serial examinations by an ophthalmologist until the ROP has regressed and normal vascularization is seen. If ROP continues to progress, laser surgery may be necessary to prevent blindness (Hack & Klein, 2006). Complications of ROP include myopia, glaucoma, and blindness. Strabismus may occur even in cases of regressed (resolved) ROP. Refractive errors and amblyopia may occur as early as 3 months corrected age. In the first year of life, ophthalmologic examinations

may occur frequently so that if corrective lenses are needed, they may be prescribed at the earliest possible time. After 1 year corrected age, former premature infants should continue to have yearly ophthalmologic examinations to detect and treat visual deficits early (Verma, Sridhar, & Spitzer, 2003).

Nursing Assessment

Ensure that all former premature infants are routinely screened for visual deficits. Discuss developmental progress with the parents. Observe for the development of strabismus, manifested by an asymmetric corneal light reflex.

Nursing Management

Nursing management of infants with ROP mainly focuses on ensuring that the family is compliant with the ophthalmologist's follow-up recommendations. Recurrent illness or rehospitalization of premature infants may interfere with scheduled eye follow-up appointments. Ensure that these appointments are rescheduled and that the family understands the importance of them. Many children who have regressed ROP or who require cryotherapy have refractive errors, so even when the ROP is considered resolved, these children should still maintain appropriate ophthalmology follow-up.

Visual Impairment

Vision impairment in children refers to acuity of between 20/60 and 20/200 in the better eye on examination. "Legal blindness" is a term used to refer to vision of less than 20/200 or peripheral vision less than 20 degrees. In most cases, vision may be augmented with corrective lenses. Some blind children can differentiate light versus dark, while others live in total darkness.

Visual impairment in children may result from a number of different causes. In the United States, visual impairment and blindness are most often caused by refractive error, astigmatism, strabismus, amblyopia, nystagmus, infantile glaucoma, congenital cataract, retinopathy of prematurity, and retinoblastoma. Factors that increase the risk for developing visual impairment include: prematurity, developmental delay, genetic syndrome, family history of eye disease, African-American heritage, previous serious eye injury, diabetes, HIV, and chronic corticosteroid use. Trauma is also an important cause of blindness in children.

Children with visual impairments often exhibit motor and cognitive delays as well. With one less sense with which to experience their environment, these children may lag behind in developmental milestones. Visual impairments are associated with many other syndromes. For example, many children with fetal alcohol syndrome have visual impairments, and albinism is associated with blindness.

▶ *Take* NOTE!

Laser pointers pose a risk of retinal damage in infants and young children. Damage occurs if the child stares at the red light for longer than 10 seconds. They should not be used as toys.

Nursing Assessment

Nursing assessment for visual impairment includes a careful health history, physical examination, and visual acuity testing.

Health History

Parents and nurses alike should be alert to signs of potential visual impairment. One of the most important functions of the nurse is to recognize signs of visual impairment as early as possible. These signs may include:

At any age:
- Dull, vacant stare

Infants:
- Does not "fix and follow"
- Does not make eye contact
- Unaffected by bright light
- Does not imitate facial expression

Toddlers and older children:
- Rub, shut, cover eyes
- Squinting
- Frequent blinking
- Holds objects close or sits close to television
- Bumping into objects
- Head tilt, or forward thrust

Physical Examination

Assess for symmetry or asymmetry of corneal light reflex. Perform the "cover test." Use an age-appropriate visual acuity screening tool (refer to Chapter 30 for additional information on visual acuity screening).

Nursing Management

Important nursing functions in relation to visual impairment and blindness are supporting the child and family and promoting socialization, development, and education. In addition, when the child with a visual impairment is hospitalized for any reason, the nurse must plan appropriate care for that child, taking into consideration the child's level of disability. Box 38.1 provides tips on working with the visually impaired child, and these tips should also be taught to families.

Supporting the Child and Family

Provide emotional support to the family with a visually impaired child. Ensure that the child's environment pro-

BOX 38.1 Tips for Interacting With the Visually Impaired Child

- Use the child's name to gain attention.
- Identify yourself and let the child know you are there before you touch the child.
- Encourage the child to be independent while maintaining safety.
- Name and describe people/objects to make the child more aware of what is happening.
- Discuss upcoming activities with the child.
- Explain what other children or individuals are doing.
- Make directions simple and specific.
- Allow the child additional time to think about the response to a question or statement.
- Use touch and tone of voice appropriate to the situation.
- Use parts of the child's body as reference points for the location of items.
- Encourage exploration of objects through touch.
- Describe unfamiliar environments and provide reference points.
- Use the sighted-guide technique when walking with a visually impaired child.

Adapted from the Delta Gamma Center for Children with Visual Impairments.

vides familiarity and security. Encourage activities that stimulate development; these activities will vary from child to child depending upon whether the child also demonstrates impairment in other areas, such as hearing or motor skills. The blind infant will not provide the eye contact that parents are looking for, so educate the parents about other indicators that the infant is acknowledging the parents' presence, such as:

- Increased motor activity
- Eyelid movement
- Changes in breathing pattern
- Making sounds

Encourage the family of a visually impaired child to display affection through touch and tone of voice. Refer families to support networks and other resources for the blind and visually impaired. Box 18.2 lists some on-line resources for families of children who are visually impaired or blind.

Promoting Socialization, Development, and Education

Blind children, since they lack the visual stimulation that children usually receive, may develop self-stimulatory actions in compensation ("blindisms"). Examples of blindisms are eye pressing, rocking, spinning, bouncing,

and head banging. These repetitive behaviors may interfere with the child's ability to socialize. Work with the parents to plan a strategy for the development of alternative behaviors specific to the individual child.

Refer the blind or visually impaired child who is younger than 3 years of age to the local district of Early Intervention to establish case management services for the child's developmental needs. After age 3, state laws provide for public education and related services for children with disabilities. An individualized education plan (IEP) should be developed to maximize the child's learning ability. Nurses may be one of the professionals involved in the development of the IEP.

The severely visually impaired or blind child will need to learn to read Braille and will also need to learn to navigate the environment with the use of a cane or via another method.

Otitis Media

Otitis media is defined as inflammation of the middle ear with the presence of fluid. It can be subdivided into two categories. Acute otitis media (AOM) refers to an acute infectious process of the middle ear that may produce a rapid onset of ear pain and possibly fever. Otitis media with effusion (OME) refers to a collection of fluid in the middle ear space without signs and symptoms of infection. Chronic otitis media with effusion (chronic OME) is defined as OME lasting longer than 3 months.

ACUTE OTITIS MEDIA

AOM is a common illness in children, resulting from infection (bacterial or viral) of fluid in the middle ear. AOM has a peak incidence between 3 and 18 months of age (Donaldson, 2006). Increased susceptibility in infants may be partly explained by the short length and horizontal positioning of the eustachian tube, limited response to antigens, and lack of previous exposure to common pathogens. AOM occurs mostly in the fall through spring, with the highest incidence in the winter. AOM often recurs in infants and young children when the fluid in the middle ear becomes reinfected. The most significant risk factors for otitis media are eustachian tube dysfunction and susceptibility to recurrent upper respiratory infections.

Pathophysiology

An upper respiratory infection frequently precedes AOM. Fluid and pathogens travel upward from the nasopharyngeal area, invading the middle ear space. Fluid behind the eardrum has difficulty draining back out toward the nasopharyngeal area because of the horizontal positioning of the eustachian tube. A viral upper respiratory infection may cause AOM or may place the child at risk for bacterial invasion. Pathogens gain access to the eustachian tube, where they proliferate and invade the mucosa. Fever and pain occur acutely. Increased pressure behind the tympanic membrane may result in perforation. This may result in decreased pain and yield drainage in the ear canal. Most perforations heal spontaneously and are completely benign.

AOM is most commonly caused by viral pathogens, *Streptococcus pneumoniae*, *Haemophilus influenzae*, and *Moraxella catarrhalis*. Viral causes of AOM resolve spontaneously.

After clearance of the infection, fluid remains in the middle ear space behind the tympanic membrane, sometimes for several months (otitis media with effusion). This may occur because of the positioning of the eustachian tubes, resulting in difficulty in draining fluid back to the nasopharyngeal area. OME may also occur because of the high frequency of upper respiratory infections in infants and young children, which again result in back-up of fluid from the nasopharyngeal area.

The most common complications of AOM include:

- Hearing loss
- Expressive speech delay
- Tympanosclerosis (scarring of the tympanic membrane; usually has no effect on hearing)
- Tympanic membrane perforation (acute with resolution or chronic)
- Chronic suppurative otitis media (chronic drainage via perforation or **tympanostomy** tubes)
- Acute mastoiditis (infection of the mastoid process)
- Intracranial infections, including bacterial meningitis and abscesses

Therapeutic Management

Viral causes of AOM usually resolve spontaneously, but bacterial causes may require treatment with an antibiotic. It is unreasonable to obtain a culture of middle ear fluid with every episode of AOM to determine the specific cause. Scientific studies of fluid obtained via tympanostomy in children with AOM have been performed, and clinical decision making is based upon this research. There is great concern in the health care community about the development of antibiotic resistance due to the overuse of antibiotics. For this reason, clinical practice guidelines have been developed for a number of disorders based upon large quantities of research.

Certain diagnosis of AOM is based upon rapid onset of symptoms, signs of fluid in the middle ear, and signs or symptoms of inflammation in the middle ear (complaint of ear pain or visible erythema of the tympanic membrane) (American Academy of Pediatrics & American Academy of Family Physicians, 2004). The choice of antibiotic will depend upon the timing, the child's age, and whether the episode is a first or subsequent infection. The current recommendations by the American Academy of Pediatrics and American Academy of Family Physicians allow for a

period of observation or "watchful waiting" in certain children. This allows for natural resolution of AOM related to viral causes and decreases the overuse of antibiotics in the pediatric population.

Recommendations for AOM treatment in previously healthy children are found in Table 18.3. Pain management is also an important component of AOM treatment, as is appropriate follow-up to ensure disease resolution.

Nursing Assessment

Nursing assessment of the child with AOM consists of health history and physical examination.

Health History

Elicit a description of the present illness and chief complaint. Note acute, abrupt onset of signs and symptoms. Common signs and symptoms reported during the health history might include:

- Fever (may be low grade or higher)
- Complaints of otalgia (ear pain)
- Fussiness or irritability
- Crying inconsolably, particularly when lying down
- Batting or tugging at the ears (may also occur with teething or OME, or may be a habit)
- Rolling the head from side to side
- Poor feeding or loss of appetite
- Lethargy
- Difficulty sleeping or awakening crying in the night
- Fluid draining from the ear

Determine the child's response to any treatments used thus far. Explore the child's current and past medical history for risk factors such as:

- Young age
- Daycare attendance
- Previous history of AOM or OME
- Antecedent or concurrent upper respiratory infection
- Other risk factors (Box 38.3)

Physical Examination and Diagnostic Testing

The child may complain of pain when the ear is examined. On otoscopic examination, the tympanic membrane will have a dull or opaque appearance and is bulging and/or red (Fig. 38.10). Sometimes pus (greenish or yellowish) may be visible behind the eardrum. Upon pneumatic otoscopy, the eardrum will be immobile. (A physician or nurse practitioner usually performs otoscopic examination.) If the tympanic membrane has become perforated, drainage may be present in the ear canal, but the canal will otherwise appear normal. Palpate for possible cervical lymphadenopathy. **Tympanometry** is not as useful in the diagnosis of AOM as it is with OME.

Nursing Management

Nursing management of the child with acute otitis media is mainly supportive in nature. It focuses on pain management, family education, and prevention of AOM.

Managing Pain Associated With AOM

Analgesics such as acetaminophen and ibuprofen have been shown to be effective at managing mild to moderate pain associated with AOM. They have the added benefit of reducing fever. Narcotic analgesics such as codeine may be prescribed for severe pain. Application of heat or a cool compress may also be helpful. Instruct the family to have the child lie on the affected side with the heating pad or covered ice pack in place to that ear. Numbing eardrops such as benzocaine (Auralgan) may be helpful in the event of acute, severe pain. They should be used in conjunction with analgesics, though, because of the short duration of action (American Academy of Pediatrics & American Academy of Family Physicians, 2004).

TABLE 38.3 TREATMENT RECOMMENDATIONS FOR AOM

Age and Severity of Illness*	Certainty of Diagnosis	Treatment
Less than 6 months old	Certain or possible	Antibiotics
6 months to 2 years	Certain	Antibiotics
6 months to 2 years with severe illness	Possible	Antibiotics
6 months to 2 years with nonsevere illness	Possible	May observe**
Greater than 2 years with severe illness	Certain	Antibiotics
Greater than 2 years with nonsevere illness	Certain	Observe**
Greater than 2 years	Possible	Observe**

*Severe illness is defined as moderate to severe otalgia or fever 39°C or higher. Nonsevere illness is defined as mild otalgia and fever less than 39°C.

**Observation is appropriate only when follow-up can be ensured. If symptoms are persistent or become worse, antibiotics may then be started.

(AAP & AAFP, 2004)

BOX 38.3 Risk Factors for Acute Otitis Media

- Eustachian tube dysfunction
- Recurrent upper respiratory infection
- First episode of AOM before 3 months of age
- Daycare attendance (increases exposure to viruses causing upper respiratory infections)
- Previous episodes of AOM
- Family history
- Passive smoking
- Crowding in the home or large family size
- Native American, Inuit, or Australian aborigine ethnicity
- Absence of infant breastfeeding
- Immunocompromise
- Poor nutrition
- Craniofacial anomalies
- Presence of allergies (possibly)

HEALTHY PEOPLE 2010

Objective	Significance
Reduce otitis media in children and adolescents	• Teach children and families the importance of hand washing to avoid the common cold (often a precursor to otitis media). • Teach families the importance of appropriate follow-up for eradication of otitis media. • Educate families about the importance of using antibiotics only for true bacterial infections (in order to decrease the development of resistant organisms, many of which cause otitis media).

Educating the Family

If the treatment selected for AOM is observation or watchful waiting, explain the rationale for this to the family. Ensure that the family understands the importance of returning for re-evaluation if the child is not improving or if the AOM progresses to severe illness. When antibiotics are prescribed, the family must understand the importance of completing the entire course of antibiotics. Families are tempted to stop giving the antibiotic because the child is usually vastly improved after taking the medication for 24 to 48 hours. Follow-up for resolution of AOM is necessary for all children, and the physician or nurse practitioner will determine the timing of that follow-up. Emphasize the importance of follow-up to the parents, educating them about OME and its potential impact on hearing and speech. See Healthy People 2010.

Preventing AOM

Breastfed infants have a lower incidence of AOM than formula-fed infants, and breast milk's immunologic benefits are well known, so encourage mothers to breastfeed for at least 6 to 12 months. Instruct families to avoid excess exposure to individuals with upper respiratory infections to decrease the incidence of these infections in their child. Infants and children should not be exposed to secondhand smoke. Encourage parents to stop smoking. If quitting smoking is not possible, then instruct parents not to smoke inside the house or automobile. Encourage the parents to have the child immunized with Prevnar and, when appropriate, influenza vaccine.

Though not yet clinically or scientifically proven, Xylitol syrup, a sucrose substitute, may also be protective.

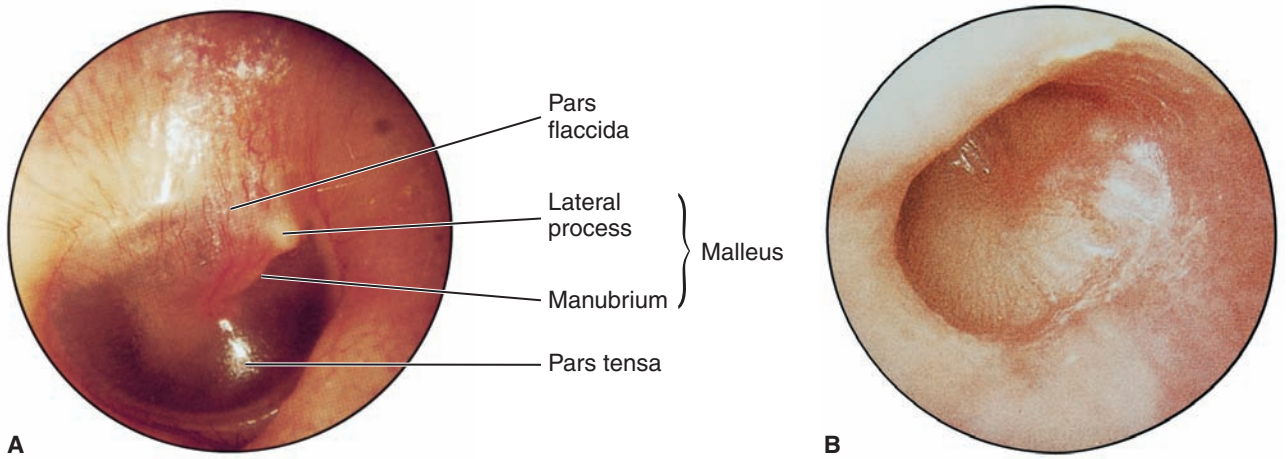

FIGURE 38.10 (**A**) Normal tympanic membrane. (**B**) Acute otitis media: note erythema and opacity of the tympanic membrane.

Children who are old enough may chew Xylitol-containing gum. Younger children and infants may be given Xylitol syrup. Care should be taken to avoid excessive dosing, as Xylitol can cause diarrhea.

OTITIS MEDIA WITH EFFUSION

Otitis media with effusion (OME) refers to the presence of fluid within the middle ear space, without signs or symptoms of infection. It may occur independent of AOM or may persist after the infectious process of AOM has resolved. Risk factors for OME include passive smoking, absence of breastfeeding, frequent viral upper respiratory infections, allergy, young age, male sex, adenoid hypertrophy, eustachian tube dysfunction, and certain congenital disorders. Complications of OME include AOM, hearing loss, and deafness.

Nursing Assessment

Nursing assessment of the child with OME includes health history, physical examination, and diagnostic testing.

Health History

Determine the extent of symptoms. Children may be asymptomatic or may experience a popping sensation or fullness behind the eardrum. Explore the health history for risk factors such as passive smoking, absence of breastfeeding, frequent viral upper respiratory infections, allergy, or recent history of AOM.

Physical Examination

Otoscopic examination may reveal a dull, opaque tympanic membrane that may be white, gray, or bluish (Fig. 38.11). If the tympanic membrane is not opaque, a fluid level or air bubble may be visualized. Mobility may be absent or diminished upon pneumatic otoscopy. Tympanometry may be used to confirm the diagnosis of OME.

FIGURE 38.11 Otitis media with effusion; note dull white tympanic membrane.

Nursing Management

OME may take several months to resolve. Nursing management during the resolution phase focuses on education and monitoring for hearing loss.

Educating the Family

Educate the family about the natural history of OME and the anatomical differences in young children that contribute to OME. Inform parents that antihistamines, decongestants, antibiotics, and corticosteroids have not been proven to hasten the resolution of OME and thus are not recommended. OME usually resolves spontaneously, but children should be rechecked every 4 weeks while this resolution is occurring. Teach parents not to feed infants in a supine position and to avoid bottle propping.

Monitoring for Hearing Loss

When OME persists, the primary concern is its effect on hearing. In the infant or toddler who should be experiencing rapid language development, impaired hearing can depress language acquisition significantly. Children with OME who are at risk for speech, language, or learning problems may be referred for evaluation of hearing earlier than a child with OME who isn't at risk (Box 18.4). Children with chronic OME (persistent OME of 3 months' duration or longer) should be referred to a specialist for hearing evaluation. Children who are not already at risk for speech concerns and are not experiencing difficulty with language acquisition may be reassessed every 3 to 6 months as long as hearing loss is not identified. At-risk children may require treatment earlier.

To communicate more effectively with children with OME who have hearing loss:

- Turn off music or television.
- Position yourself within 3 feet of the child before speaking.
- Face the child while speaking.

BOX 38.4 Children at Risk for Speech, Language, or Learning Difficulties

- Permanent hearing loss (without OME)
- Speech/language delay (suspected or diagnosed)
- Craniofacial disorder that may interfere with speech
- Any pervasive developmental disorder
- Genetic disorders or syndromes associated with speech or learning problems
- Cleft palate
- Blindness or significant visual impairment

- Use visual cues.
- Increase the volume of your speech only slightly.
- Speak clearly.
- Request preferential classroom seating.

Take NOTE!

Evaluation of hearing is recommended when OME lasts 3 months or more if language delay, hearing loss, or a learning problem is suspected.

Providing Postoperative Care for the Child With Pressure-Equalizing Tubes

The standard treatment for persistent or problematic OME is surgical insertion of **pressure-equalizing (PE) tubes** into the tympanic membrane (via myringotomy). The tubes stay in place for at least several months and generally fall out on their own (Fig. 38.12). The procedure is usually done as an outpatient surgery and the child returns home in the evening. Teach the parents to administer ear drops postoperatively if prescribed. After PE tube placement, the surgeon may recommend avoiding water entry into the ears. If recommended, advise parents to have the child wear earplugs in the bathtub or while swimming.

Placement of the PE tubes allows for adequate hearing, which in turn encourages appropriate speech development. Placement of PE tubes does not prevent middle ear infection. If the middle ear becomes infected with PE tubes in place, the tubes allow infected fluid to drain from the ear. Tell parents to contact their pediatrician if drainage from the ear is noted. After PE tubes are placed, young children often have rapid increases in language acquisition, and parents should observe for this.

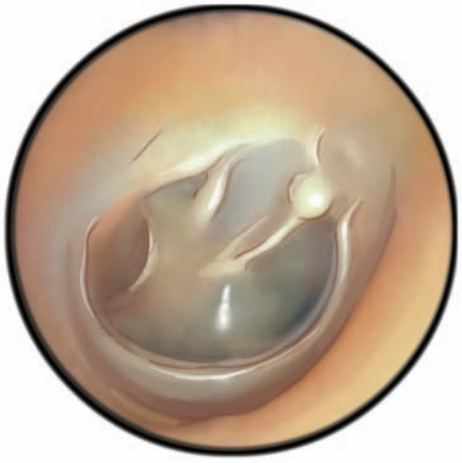

FIGURE 38.12 Pressure-equalizing tubes in place in the tympanic membrane.

Take NOTE!

Children with PE tubes who swim in a lake must wear earplugs, as lake water is contaminated with bacteria and entry of that water into the middle ear should be avoided.

OTITIS EXTERNA

Otitis externa is defined as an infection and inflammation of the skin of the external ear canal. *Pseudomonas aeruginosa* and *Staphylococcus aureus* are typical causative agents, though fungi such as *Aspergillus* and other bacteria also may be implicated. Moisture in the canal contributes to pathogen growth. Otitis externa is commonly known as "swimmer's ear" since it occurs more frequently in those who swim often (and thus have wet ear canals). Changing the pH in the ear canal contributes to the inflammatory process (Zoltan, Taylor, & Achar, 2005).

Nursing Assessment

Nursing assessment of the child with otitis externa focuses on the health history and physical examination.

Health History

Elicit a description of the present illness and chief complaint. Note history of ear itching or pain, ear drainage, or a feeling of fullness in the ear canal, with possible difficulty hearing. Note onset and progression of symptoms, as well as the child's response to treatments. Explore the child's current and past medical history for risk factors such as previous episodes of otitis externa or history of recent swimming in a pool, lake, or ocean.

Take NOTE!

The child with otitis externa usually has significant ear pain. Pressure on the tragus should be avoided, as it can worsen the pain.

Physical Examination

Typically a white or colored discharge can be seen in the ear canal or running from the ear. On otoscopy, the canal is red and edematous, often too swollen for insertion of the speculum and viewing of the tympanic membrane (Fig. 38.13). Diagnosis is based on clinical findings. Occasionally the ear drainage is cultured for bacteria or fungus, particularly if otitis externa is not improving with treatment.

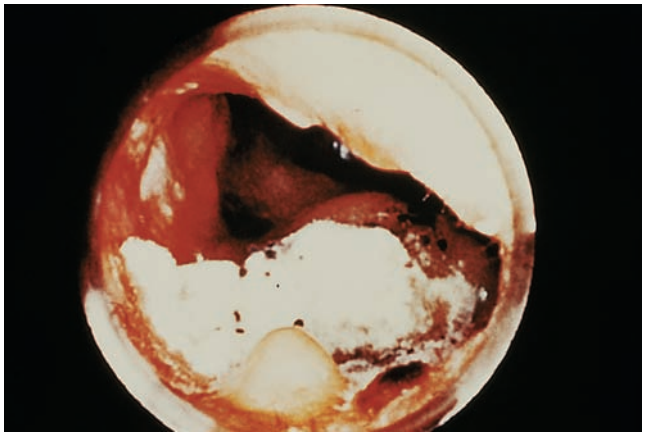

FIGURE 38.13 Note edema and erythema of the ear canal as well as purulent discharge in the child with otitis externa.

Nursing Management

The primary goals of nursing management are pain relief, treatment of the infection, and prevention of recurrence.

Managing Pain

Analgesics (often narcotics) may be administered to manage the pain. A warm compress or heating pad to the affected ear is helpful in some children.

Treating the Infection

Antibiotic or antifungal eardrops should be administered as prescribed. In some cases a wick is placed in the ear canal. The wick keeps the antibiotic drops in contact with the skin of the ear canal and promotes healing. Wick insertion can be extremely painful, and younger children will need to be restrained during insertion for their safety.

Preventing Reinfection

Once the infection has resolved, children and their parents should be educated about prevention of further episodes. Since moisture contributes to otitis externa, the ear canals should be kept dry. Encourage the child and parents to use one of the methods described in Teaching Guidelines 38.2 after swimming or showering.

TEACHING GUIDELINES 38.2

Preventing Otitis Externa

1. Avoid the use of cotton swabs, headphones, and earphones.
2. Wear earplugs when swimming.
3. Promote ear canal dryness and alternate pH. Use one or more of the following methods:
   - Dry the ear canals using a hair dryer set on a lower setting.
   - Administer solutions that have a drying effect on the auditory canal skin and change the pH of the canal to discourage organism growth in susceptible children. The following solutions can be used:
     - A few drops of Domeboro solution can be placed in the canal, and then allowed to run out.
     - A mixture of half rubbing alcohol and half vinegar (squirted into the canal and then allowed to run out). The alcohol solution should be used only when the ear canals are healthy. Using it while the canals are inflamed will cause stinging and increased pain.

Hearing Loss and Deafness

Infants are ordinarily born with the sense of hearing fully developed. Language development in infancy and early childhood is dependent upon adequate hearing, and even the fluctuating hearing loss associated with intermittent bouts of AOM can hinder language development. Hearing loss may be unilateral (involving one ear) or bilateral (involving both ears). The extent of hearing loss is defined based on the softest intensity of sound that is perceived, described in **decibels** (dB). Levels of hearing loss are:

- 0 to 20 dB: normal
- 20 to 40 dB: mild loss
- 40 to 60 dB: moderate loss
- 60 to 80 dB: severe loss
- Greater than 80 dB: profound loss (ASHA, 2007)

Hearing loss may be congenital or of delayed onset. Congenital hearing loss affects about 3 infants per 1,000 live births in the United States (NCHAM, 2007b). Most congenital hearing loss is inherited through a recessive gene, with only about 22% of cases resulting from an autosomal dominant trait (Kaye, 2006). Congenital hearing loss accounts for about one half of all the cases of hearing impairment; the remainder are acquired. Premature infants and those with persistent pulmonary hypertension of the newborn are at increased risk for hearing loss compared with other infants (Verma et al., 2003). Hearing loss commonly occurs with a large number of congenital or genetic syndromes, as well as in association with anomalies of the head and face. As of 2005, a variety of newborn universal hearing screening mandates have been passed by legislation in 37 states, thus allowing for earlier identification of infants with congenital hearing loss (NCHAM, 2007a). See Healthy People 2010.

Delayed-onset hearing loss may be conductive, sensorineural, or mixed. **Conductive hearing loss** results when transmission of sound through the middle ear is disrupted, as in the case of OME. When fluid fills the middle ear, the tympanic membrane is unable to move properly, and partial or complete hearing loss occurs. **Sensorineural hearing loss** is caused by damage to the hair cells in the

HEALTHY PEOPLE 2010

Objective	Significance
(Developmental) Increase the proportion of newborns who are screened for hearing loss by age 1 month, have audio-logic evaluation by age 3 months, and are enrolled in appropriate intervention services by age 6 months	• Encourage appropriate hearing assessments. • Refer children who are diagnosed with a hearing deficit to local services for the deaf or hearing impaired.

cochlea or along the auditory pathway. This may result from kernicterus, use of ototoxic medication, intrauterine infection with cytomegalovirus or rubella, neonatal or postnatal infection such as meningitis, severe neonatal respiratory depression, or exposure to excess noise. Mixed hearing loss occurs when the cause may be attributed to both conductive and sensorineural problems. See Healthy People 2010.

Regardless of the cause of hearing loss, early intervention can make a difference in the child's ability to communicate. Once the hearing loss has been determined, intervention can begin. Hearing aids, cochlear implants, communication devices, and speech education may enable these children to communicate verbally. Improved communication beginning in infancy and early childhood may also improve the child's school achievement.

▶ ***Take NOTE!***

The earplugs or covers used to block ambient noise in premature infants in the NICU may decrease the preemie's risk for hearing loss.

Nursing Assessment

Nursing assessment of the child with hearing loss or impairment focuses on the health history, physical examination, and hearing testing.

HEALTHY PEOPLE 2010

Objective	Significance
(Developmental) Increase the use of appropriate ear protection devices, equipment, and practices. Reduce noise-induced hearing loss in children and adolescents aged 17 years and under.	• Educate children and families about the dangers of excess noise and its potential for damaging hearing. • Encourage appropriate use of ear protection devices.

Health History

Common signs and symptoms reported during the health history might include:

Infant:
- Wakes only to touch, not environmental noises
- Does not startle to loud noises
- Does not turn to sound by 4 months of age
- Does not babble at 6 months of age
- Does not progress with speech development

Young child:
- Does not speak by 2 years of age
- Communicates needs through gestures
- Does not speak distinctly, as appropriate for his or her age
- Displays developmental (cognitive) delays
- Prefers solitary play
- Displays immature emotional behavior
- Does not respond to ringing of the telephone or doorbell
- Focuses on facial expressions when communicating

Older child:
- Often asks for statements to be repeated
- Is inattentive or daydreams
- Performs poorly at school
- Displays monotone or other abnormal speech
- Gives inappropriate answers to questions except when able to view face of speaker

At any age:
- Speaks loudly
- Sits very close to TV or radio or turns volume too loud
- Responds only to moderate or loud voices

Signs of hearing loss should be investigated as early as possible in order for appropriate communication intervention to begin.

Explore the child's current and past medical history for risk factors such as congenital anomalies, genetic syndrome, infection, family history, kernicterus, neonatal ventilator use, ototoxic medication, or exposure to excess noise. Note whether newborn hearing screening was done, along with the results.

Physical Examination and Laboratory and Diagnostic Tests

Determine the child's level of interaction with the environment. For preschoolers and older children, administer the whisper test, keeping in mind that this is a gross screening test only. Perform the Weber and Rinne tests (refer to Chapter 30 for further explanation). If further evaluation is needed, the nurse may be responsible for administering an otoacoustic emissions test or auditory brain stem evoked response test, either in the hospital or outpatient office.

Nursing Management

The primary goal of nursing care for the child with a hearing impairment is to provide education and support to the family and child. Individualize care for the child with a hearing impairment and the family based on their specific responses to the hearing impairment.

Augmenting Hearing

Compliance with hearing aids and communication curriculums is critical so that the child can develop hearing and speech. Hearing aids should be cleaned daily with a damp cloth. Batteries are usually changed weekly. When inserting the aid, the volume should be turned down, then adjusted to the appropriate level after insertion. As the infant or child grows, the hearing aid will need to be reassessed for proper fit. Many deaf schools and other organizations provide loaner hearing aids so that the best fit and amplification may be determined prior to purchase. Assist the family to explore this type of option in the local community. See Healthy People 2010.

When cochlear implants are used, the nurse focuses on postoperative care of the incision site and pain management.

Promoting Communication and Education

Families and children need to learn how to communicate effectively with one another. If the child learns American Sign Language, for instance, the parents and siblings should as well. Table 38.4 provides information on communication options for hearing-impaired children and their families. Communication may also be enhanced by the use of text telephone service in the home and closed-caption television. Bells and alarms in the home may use lights rather than sound to alert the child. Provide a sign language interpreter for the child at health care visits if the parent is not present for interpretation.

HEALTHY PEOPLE 2010

Objective	Significance
(Developmental) Increase access by persons who have hearing impairments to hearing rehabilitative services and adaptive devices, including hearing aids, cochlear implants, or tactile or other assistive or augmentative devices	• Know resources available in the local area for the deaf and hearing impaired. • Refer children with hearing deficits to these resources and to service providers for augmentative devices.

Encouraging Education

Refer the child less than 3 years of age to the local district of Early Intervention for case management of developmental needs. At 3 years of age and beyond, state laws provide for public education and related services for children with disabilities. An IEP should be developed to maximize the child's learning ability. Nurses may be involved in the development of the IEP.

Some children attend schools specifically geared toward deaf students. The choice of school will depend upon the family's preferences and resources.

Providing Support

The diagnosis of a significant disability can be extremely stressful for the family. Encourage families to express their feelings and provide emotional support. Ensure that the needs of any siblings are also attended to. When the family is ready, encourage them to network with other families

TABLE 38.4 COMPARING COMMUNICATION OPTIONS FOR THE HEARING IMPAIRED

Spoken Language	
Oral deaf education (auditory-verbal therapy)	Uses technology to boost auditory potential; teaches children to notice sound and give it meaning. Develops oral speech.
Cued speech	A system using hand signs to clarify lip-reading; gives the person clues about the sounds the speaker is making.
Signed Language	
American Sign Language (ASL)	Entirely communicated through hand signs, gestures, and facial expressions. Has its own grammar and syntax.
Combination: Total Communication	Combines auditory training and teaching of spoken language with SEE ("signing exact English"; corresponds to the words and syntax of English).
Augmentative and Alternative Communication (AAC)	
May use gestural communication	Can also include physical devices such as notebooks, communication boards, charts, or computers. Ranges from very low-tech to technologically complex.

who have children with similar needs. Educate the family about the child's prescribed plan of care. Refer families to resources and support groups (Box 38.5).

Key Concepts

- Though hearing is fully developed at birth, visual development continues to progress until about age 7 years.
- The relatively short and horizontally positioned eustachian tubes of infants and young children make them more susceptible to otitis media than adults.
- Binocular vision develops by age 4 months; visual acuity progresses to 20/50 by age 3 years and usually reaches 20/20 by age 7 years.
- To maximize speech and language development, hearing loss should be identified early and intervention begun immediately.
- The corneal light reflex test and cover test are useful tools for identifying strabismus and amblyopia.
- Tympanometry is used to determine the presence of fluid behind the eardrum (such as with otitis media with effusion).
- Topical ophthalmic medications are used to treat certain infectious eye disorders.
- Systemic antibiotics are used for the treatment of periorbital cellulitis and acute otitis media.
- Very premature infants are at high risk of developing visual deficits related to retinopathy of prematurity and are also at increased risk of hearing impairment compared to other infants.
- Children with genetic syndromes or family history are at increased risk of visual and hearing impairments.
- Strabismus, glaucoma, and cataracts may all lead to visual impairment if left untreated.
- Recurrent or constant nasal congestion contributes to otitis media with effusion.
- Asymmetry of the corneal light reflex occurs with true strabismus.
- A cloudy cornea indicates the presence of cataract.
- Eye strain, eye rubbing, and headaches may indicate a visual deficit.
- Delay in language acquisition may occur when hearing loss is present.
- Appropriate hand washing is the single most important factor to reduce the spread of acute viral or bacterial conjunctivitis.
- Otitis externa can be prevented by keeping the ear canal dry and altering canal pH.
- Children with visual disorders should be encouraged to use prescribed corrective lenses.
- The child with hearing loss should receive early intervention with hearing aids or other augmentative devices.
- Hearing and/or vision impairment can significantly hinder developmental progress.
- The fluctuating hearing loss associated with recurrent otitis media and the hearing loss associated with chronic otitis media with effusion can both significantly hinder language development in the infant and toddler.
- Amblyopia must be identified early and treated with patching, corrective lenses, or surgery to prevent visual deterioration and promote appropriate vision development.

Chapter Worksheet

Multiple Choice Questions

1. Which situation would cause the nurse to become concerned about possible hearing loss?
   a. A 12-month-old who babbles incessantly, making no sense
   b. An 8-month-old who says only "da"
   c. A 3-month-old who startles easily to sound
   d. A 3-year-old who drops the letter "s"
2. A 4-year-old complains of extreme pain when the tragus is touched. Though not diagnostic, this sign is most indicative of which disorder?
   a. Acute otitis media
   b. Acute tympanic effusion
   c. Otitis interna
   d. Otitis externa
3. The nurse is caring for an infant who has undergone surgery for infantile glaucoma. What is the priority nursing intervention?
   a. Place the child prone postoperatively for comfort.
   b. Teach the family use of the contact lens.
   c. Place elbow restraints on the infant.
   d. Provide a mobile for optical stimulation.
4. A 2-year-old has been prescribed eye patching for strabismus 6 hours per day. What teaching does the nurse provide for the mother?
   a. Try to patch 6 hours per day, but if you miss some it is OK.
   b. Patching is necessary to strengthen vision in the weaker eye.
   c. Patching will keep the eye from turning in.
   d. Since the child is so young, patching can be delayed until school age.

Critical Thinking Exercises

1. A 16-month-old toddler is being seen for his sixth ear infection. What particular information about his growth and development must the nurse ask about? Be specific about the questions you would ask.
2. How would you distinguish allergic conjunctivitis from acute bacterial conjunctivitis?
3. A 13-month-old has been diagnosed with severe visual impairment. Develop a list of sample nursing diagnoses for this situation.

Study Activities

1. Develop a sample plan for teaching a low-literacy parent about the etiology, treatment, and complications of recurrent acute otitis media.
2. While in the pediatric clinical setting, compare the play styles of a sighted child with those of a visually impaired child.
3. Research hearing and vision resources in your local community.

CHAPTER 39

Nursing Care of the Child With a Respiratory Disorder

Alexander Roberts, 4 months old, is brought to the clinic by his mother. He has a cold and has been coughing a great deal for 2 days. Today he has had difficulty taking his bottle and is breathing very quickly. Mrs. Roberts says he seems tired.

KEY TERMS

atelectasis
atopy
clubbing
coryza
cyanosis
expiration
hypoxemia
hypoxia
infiltrate
inspiration
laryngitis
oxygenation
pharyngitis
pulmonary
pulse oximetry
rales
retractions
rhinitis
rhinorrhea
stridor
subglottic stenosis
suctioning
tachypnea
tracheostomy
ventilation
wheeze
work of breathing

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Discuss how the anatomy and physiology of the respiratory system in children differs from that of adults.
2. Identify various factors associated with respiratory illness in infants and children.
3. Discuss common laboratory and other diagnostic tests useful in the diagnosis of respiratory conditions.
4. Discuss common medications and other treatments used for treatment and palliation of respiratory conditions.
5. Recognize risk factors associated with various respiratory disorders.
6. Distinguish different respiratory illnesses based on their signs and symptoms.
7. Discuss nursing interventions commonly used for respiratory illnesses.
8. Devise an individualized nursing care plan for the child with a respiratory disorder.
9. Develop client/family teaching plans for the child with a respiratory disorder.
10. Describe the psychosocial impact of chronic respiratory disorders on children.

Wow

Restoring a full breath allows a child to participate fully in life's adventures.

Respiratory disorders are the most common causes of illness and hospitalization in children. These illnesses range from mild, non-acute disorders (such as the common cold or sore throat) to serious life-threatening conditions (such as epiglottitis). Chronic disorders, such as allergic rhinitis or asthma, can affect quality of life, but frequent acute or recurrent infections also can interfere significantly with the well-being of some children.

Respiratory infections account for the majority of acute illnesses in children. The child's age and living conditions as well as the season of the year can influence the development of respiratory disorders in addition to the course of illness. For example, low-income children have a higher risk for increased severity or increased frequency of disease. Infants and younger children are more likely to deteriorate quickly from a respiratory illness. Certain viruses are more prevalent in the winter, whereas allergen-related respiratory diseases are more prevalent in the spring and fall. Children with chronic illness such as diabetes, congenital heart disease, sickle cell anemia, and cystic fibrosis and children with developmental disorders such as cerebral palsy tend to be more severely affected with respiratory disorders. Parents may have difficulty determining the severity of their child's condition and might either seek care very early in the course of the illness (when it is still very mild) or wait and present to the health care setting when the child is very ill.

Nurses must be familiar with respiratory conditions affecting children so that they can provide guidance and support to families. When children become ill, families often encounter nurses in outpatient settings first. Nurses must be able to ask questions that can help establish the severity of the child's illness and determine whether they must seek care at a health facility. Since respiratory illnesses account for the majority of pediatric admissions to general hospitals, nurses caring for children need to have expert assessment and intervention skills in this area. Detection of worsening respiratory status early in the course of deterioration allows for timely treatment and the chance to prevent a minor problem from becoming a critical illness.

Difficulty with breathing can be very frightening for both the child and parents. The child and the family need the nurse's support throughout a respiratory illness. Nurses are also in the unique position of being able to reduce the burden of respiratory illness in children by identifying these illnesses early, providing education about them, and promoting prevention efforts.

Variations in Pediatric Anatomy and Physiology

Respiratory conditions often affect both the upper and lower respiratory tract, though some affect primarily one or the other. Respiratory dysfunction in children tends to be more severe than in adults, and several differences in the infant's or child's respiratory system account for this increased severity.

HEALTHY PEOPLE 2010

Objective	Significance
Reduce hospitalization rates for three ambulatory-care-sensitive conditions: pediatric asthma and immunization-preventable pneumonia and influenza.	• Appropriately educate children with asthma and their families about the ongoing management of asthma. • Encourage pneumococcal and influenza vaccinations per recommendations.

Nose

Newborns are obligatory nose breathers until at least 4 weeks of age. The young infant cannot automatically open his or her mouth to breathe if the nose is obstructed. The nares must be patent for breathing to be successful while feeding. Newborns breathe through their mouths only while crying.

The upper respiratory mucus serves as a cleansing agent, yet newborns produce very little mucus, making them more susceptible to infection. However, the newborn and young infant may have very small nasal passages, so when excess mucus is present, airway obstruction is more likely.

Infants are born with maxillary and ethmoid sinuses present. The frontal sinuses (most often associated with sinus infection) and the sphenoid sinuses develop by age 6 to 8 years, so younger children are less apt to acquire sinus infections than are adults.

Throat

The tongue of the infant relative to the oropharynx is larger than in adults. Posterior displacement of the tongue can quickly lead to severe airway obstruction. Through early school age, children tend to have enlarged tonsillar and adenoidal tissue even in the absence of illness. This can contribute to an increased incidence of airway obstruction.

Trachea

The airway lumen is smaller in infants and children than in adults. The infant's trachea is approximately 4 mm wide compared with the adult width of 20 mm. When edema, mucus, or bronchospasm is present, the capacity for air passage is greatly diminished. A small reduction in the diameter of a child's airway can significantly increase resistance to airflow, leading to increased **work of breathing** (Fig. 39.1).

In teenagers and adults the larynx is cylindrical and fairly uniform in width. In infants and children less than 10 years old, the cricoid cartilage is underdeveloped, resulting in laryngeal narrowing. Thus, in infants and children, the larynx is funnel-shaped. When any portion of

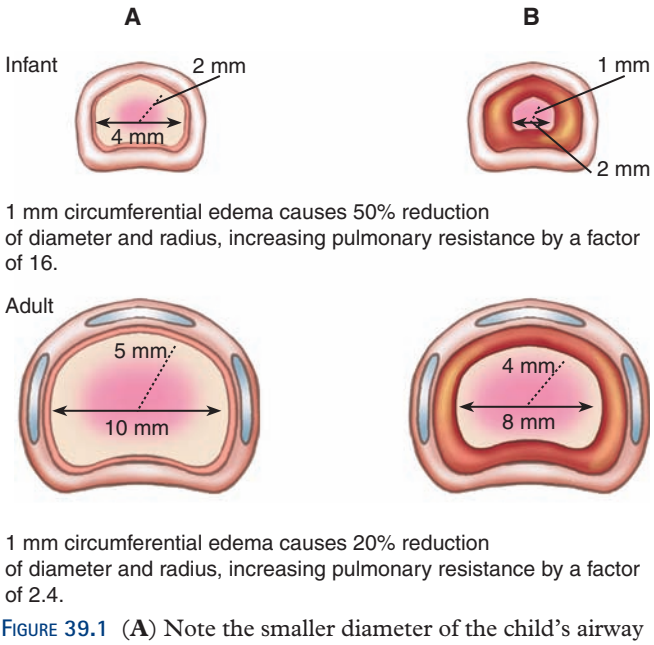

FIGURE 39.1 (**A**) Note the smaller diameter of the child's airway under normal circumstances. (**B**) With 1 cm of edema present, note the exponential decrease in airway lumen diameter as compared with the adult.

the airway is narrowed, further narrowing from mucus or edema will result in an exponential increase in resistance to airflow and work of breathing. In infants and children, the larynx and glottis are located higher in the neck, increasing the chance of aspiration of foreign material into the lower airways. Congenital laryngomalacia occurs in some infants and results in the laryngeal structure being weaker than normal, yielding greater collapse on **inspiration**. Box 39.1 discusses congenital laryngomalacia.

The child's airway is highly compliant, making it quite susceptible to dynamic collapse in the presence of airway obstruction. The muscles supporting the airway are less functional than those in the adult. Children have a large amount of soft tissue surrounding the trachea, and the mucous membranes lining the airway are less securely attached compared with adults. This increases the risk for airway edema and obstruction. Upper airway obstruction resulting from a foreign body, croup, or epiglottitis can result in tracheal collapse during inspiration.

BOX 39.1 Congenital Laryngomalacia

- Inspiratory stridor is present and is intensified with certain positions.
- Suprasternal retractions may be present, but the infant exhibits no other signs of respiratory distress.
- Congenital laryngomalacia is generally a benign condition that improves as the cartilage in the larynx matures. It usually disappears by age 1 year.
- The crowing noise heard with breathing can make parents very anxious. Reassure parents that the condition will improve with time.
- Parents become very familiar with the "normal" sound their infant makes and are often able to identify intensification or change in the stridor. Airway obstruction may occur earlier in infants with this condition, so intensification of stridor or symptoms of respiratory illness should be evaluated early by the primary care provider.

Lower Respiratory Structures

The bifurcation of the trachea occurs at the level of the third thoracic vertebra in children, compared to the level of the sixth thoracic vertebra in adults. This anatomic difference is important when suctioning children and when endotracheal intubation is required (see Chapter 52 for further discussion). This difference in placement also contributes to risk for aspiration. The bronchi and bronchioles of infants and children are also narrower in diameter than the adult's, placing them at increased risk for lower airway obstruction (see Fig. 39.1). Lower airway obstruction during exhalation often results from bronchiolitis or asthma or is caused by foreign body aspiration into the lower airway.

Alveoli develop at approximately 24 weeks' gestation. Term infants are born with about 50 million alveoli. After birth, alveolar growth slows until 3 months of age and then progresses until the child reaches 7 or 8 years of age, at which time the alveoli reach the adult number of around 300 million. Alveoli make up most of the lung tissue and are the major sites for gas exchange. Oxygen moves from the alveolar air to the blood, while carbon dioxide moves from the blood into the alveolar air. Smaller numbers of alveoli, particularly in the premature and/or young infant, place the child at a higher risk of **hypoxemia** and carbon dioxide retention.

Chest Wall

In older children and adults the ribs and sternum support the lungs and help keep them well expanded. The movement of the diaphragm and intercostal muscles alters volume and pressure within the chest cavity, resulting in air movement into the lungs. Infants' chest walls are highly compliant (pliable) and fail to support the lungs adequately. Functional residual capacity can be greatly reduced if respiratory effort is diminished. This lack of lung support also makes the tidal volume of infants and toddlers almost completely dependent upon movement of the diaphragm. If diaphragm movement is impaired (as in states of hyperinflation such as asthma), the intercostal muscles cannot lift the chest wall and respiration is further compromised.

Metabolic Rate and Oxygen Need

Children have a significantly higher metabolic rate than adults. Their resting respiratory rates are faster and their demand for oxygen is higher. Adult oxygen consumption is 3 to 4 liters per minute, while infants consume 6 to 8 liters per minute. In any situation of respiratory distress,

infants and children will develop hypoxemia more rapidly than adults. This may be attributed not only to the child's increased oxygen requirement but also to the effect that certain conditions have on the oxyhemoglobin dissociation curve.

Normal oxygen transport relies upon binding of oxygen to hemoglobin in areas of high pO_2 (pulmonary arterial beds) and release of oxygen from hemoglobin when the partial pressure of oxygen (pO_2) is low (peripheral tissues). Normally, a pO_2 of 95 mm Hg results in an oxygen saturation of 97%. A decrease in oxygen saturation results in a disproportionate (much larger) decrease in pO_2 (Fig. 39.2). Thus, a small decrease in oxygen saturation reflects a larger decrease in pO_2. Conditions such as alkalosis, hypothermia, hypocarbia, anemia, and fetal hemoglobin cause oxygen to become more tightly bound to hemoglobin, resulting in the curve shifting to the left. Common pediatric conditions such as acidosis, hyperthermia, and hypercarbia cause hemoglobin to decrease its affinity for oxygen, further shifting the curve to the right.

Common Medical Treatments

A variety of interventions are used to treat respiratory illness in children. The treatments listed in Common Medical Treatments 39.1 and Drug Guide 39.1 usually require a physician's order when a child is hospitalized.

NURSING PROCESS OVERVIEW FOR THE CHILD WITH A RESPIRATORY DISORDER

Care of the child with a respiratory disorder includes assessment, nursing diagnosis, planning, interventions, and evaluation. There are a number of general concepts related to the nursing process that can be applied to respiratory disorders. From a general understanding of the care involved for a child with respiratory dysfunction, the nurse can then individualize the care based on client specifics.

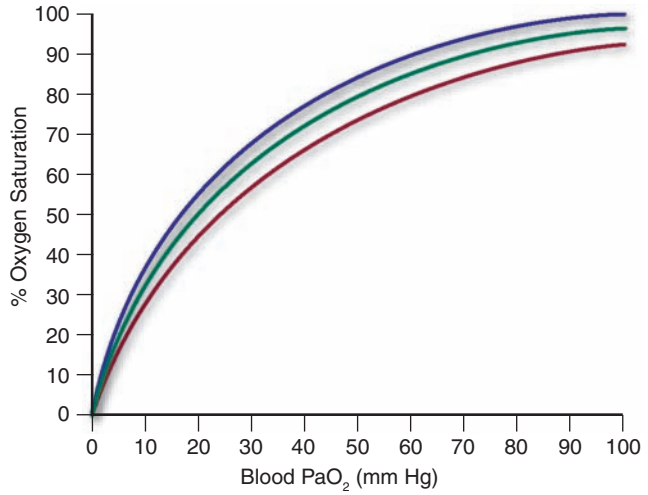

FIGURE 39.2 Normal hemoglobin dissociation curve (*green*), shift to the right (*red*), and shift to the left (*black*).

Assessment

Assessment of respiratory dysfunction in children includes health history, physical examination, and laboratory or diagnostic testing.

Remember Alexander, the 4-month-old with the cold, cough, fatigue, feeding difficulty, and fast breathing? What additional health history and physical examination assessment information should the nurse obtain?

Health History

The health history comprises past medical history, family history, and history of present illness (when the symptoms started and how they have progressed) as well as treatments used at home. The past medical history might be significant for recurrent colds or sore throats, **atopy** (such as asthma or atopic dermatitis), prematurity, respiratory dysfunction at birth, poor weight gain, or history of recurrent respiratory illnesses or chronic lung disease. Family history might be significant for chronic respiratory disorders such as asthma or might reveal contacts for infectious exposure. When eliciting the history of the present illness, inquire about onset and progression, fever, nasal congestion, noisy breathing, presence and description of cough, rapid respirations, increased work of breathing, ear, nose, sinus, or throat pain, ear pulling, headache, vomiting with coughing, poor feeding, and lethargy. Also inquire about exposure to second-hand smoke. Children exposed to environmental smoke have an increased incidence of respiratory illnesses such as asthma, bronchitis, and pneumonia (Sheahan & Free, 2005).

Physical Examination

Physical examination of the respiratory system includes inspection and observation, auscultation, percussion, and palpation.

Inspection and Observation

Color. Observe the child's color, noting pallor or cyanosis (circumoral or central). Pallor (pale appearance) occurs as a result of peripheral vasoconstriction in an effort to conserve oxygen for vital functions. **Cyanosis** (a bluish tinge to the skin) occurs as a result of **hypoxia**. It might first present circumorally (just around the mouth) and progress to central cyanosis. Newborns might have blue hands and feet (acrocyanosis), a normal finding. The infant might have pale hands and feet when cold or when ill, as peripheral circulation is not well developed in early

COMMON MEDICAL TREATMENTS 39.1 Respiratory Disorders

Treatment	Explanation	Indications	Nursing Implications
Oxygen	Supplemented via mask, nasal cannula, hood, or tent or via endotracheal or nasotracheal tube	Hypoxemia, respiratory distress	Monitor response via work of breathing and pulse oximetry.
High humidity	Addition of moisture to inspired air	Common cold, croup, tonsillectomy	Infant may require extra blankets with cool mist, and frequent changes of bedclothes under oxygen hood or tent as they become damp.
Suctioning	Removal of secretions via bulb syringe or suction catheter	Excessive airway secretions (common cold, flu, bronchiolitis, pertussis)	Should be done carefully and only as far as recommended for age or tracheostomy tube size, or until cough or gag occurs.
Chest physiotherapy (CPT) and postural drainage	Promotes mucus clearance by mobilizing secretions with the assistance of percussion or vibration accompanied by postural drainage	Bronchiolitis, pneumonia, cystic fibrosis, or other conditions resulting in increased mucus production. Not effective in inflammatory conditions without increased mucus.	May be performed by respiratory therapist in some institutions, by nurses in others. In either case, nurses must be familiar with the technique and able to educate families on its use.
Saline gargles	Relieves throat pain via salt water gargle	Pharyngitis, tonsillitis	Recommended for children old enough to understand the concept of gargling (to avoid choking)
Saline lavage	Normal saline introduced into the airway, followed by suctioning	Common cold, flu, bronchiolitis, any condition resulting in increased mucus production in the upper airway	Very helpful for loosening thick mucus; child may need to be in semi-upright position to avoid aspiration
Chest tube	Insertion of a drainage tube into the pleural cavity to facilitate removal of air or fluid and allow full lung expansion	Pneumothorax, empyema	Should tube become dislodged from container, the chest tube must be clamped immediately to avoid further air entry into the chest cavity.
Bronchoscopy	Introduction of a bronchoscope into the bronchial tree for diagnostic purposes. Also allows for bronchiolar lavage.	Removal of foreign body, cleansing of bronchial tree	Watch for postprocedure airway swelling, complaints of sore throat.

infancy. It is important, then, to note if the cyanosis is central (involving the midline), as this is a true sign of hypoxia. Children with low red blood cell counts might not demonstrate cyanosis as early in the course of hypoxemia as children with normal hemoglobin levels. Therefore, absence of cyanosis or the degree of cyanosis present is not always an accurate indication of the severity of respiratory involvement.

Note the rate and depth of respiration as well as work of breathing. Often the first sign of respiratory illness in infants and children is **tachypnea**.

▶ *Take* NOTE!

A slow or irregular respiratory rate in an acutely ill infant or child is an ominous sign. See Chapter 52.

Nose and Oral Cavity. Inspect the nose and oral cavity. Note nasal drainage and redness or swelling in the nose. Note the color of the pharynx, presence of exudate,

DRUG GUIDE 39.1 COMMON DRUGS FOR RESPIRATORY DISORDERS

Medication	Action/Indications	Nursing Implications
Expectorant (guaifenesin)	Reduces viscosity of thickened secretions by increasing respiratory tract fluid Used for the common cold, pneumonia, and other conditions requiring mobilization and subsequent expectoration of mucus	Encourage deep breathing before coughing in order to mobilize secretions. Maintain adequate fluid intake. Assess breath sounds frequently.
Cough suppressants (dextromethorphan, codeine, hydrocodone)	Relieves irritating, nonproductive cough by direct effect on the cough center in the medulla, which suppresses the cough reflex Used for the common cold, sinusitis, pneumonia, bronchitis	Should be used only with nonproductive coughs in the absence of wheezing
Antihistamines	Treatment of allergic conditions such as allergic rhinitis, asthma	May cause drowsiness or dry mouth
Antibiotics (oral, parenteral)	Treatment of bacterial infections of the respiratory tract such as pharyngitis, tonsillitis, sinusitis, bacterial pneumonia, cystic fibrosis, empyema, abscess, tuberculosis	Check for antibiotic allergies. Should be given as prescribed for the length of time prescribed.
Antibiotics (inhaled)	Treatment of bacterial infections of the respiratory tract in children with cystic fibrosis	Can be given via nebulizer
Beta2-adrenergic agonists (short-acting) (i.e., albuterol, levalbuterol)	Relax airway smooth muscle, resulting in bronchodilation Used for acute and chronic treatment of wheezing and bronchospasm in asthma, bronchiolitis, cystic fibrosis, chronic lung disease. Also used to prevent wheezing in exercise-induced asthma.	May be administered orally or via inhalation Can be used for acute relief of bronchospasm May cause nervousness, tachycardia, and jitteriness Inhaled agents result in fewer systemic side effects.
Beta2-adrenergic agonists (long-acting) (i.e., salmeterol)	Long-acting bronchodilator used in chronic asthma management and for prevention of exercise-induced asthma Long-term control in chronic asthma Prevention of exercise-induced asthma	Administered via inhalation Used only for long-term control or for exercise-induced asthma. Not for relief of bronchospasm in an acute wheezing episode.
Racemic epinephrine	Produces bronchodilation Indicated for croup	Assess lung sounds and work of breathing. Observe for rebound bronchospasm.
Anticholinergic (ipratropium)	Produces bronchodilation in asthma or chronic lung disease	In children, generally used as an adjunct to beta2-adrenergic agonists for treatment of bronchospasm
Antiviral agents (amantadine, rimantidine, zanamivir, oseltamivir)	Treatment and prevention of influenza A	Amantadine, rimantidine: Monitor for confusion, nervousness, and jitteriness. Zanamivir, oseltamivir: Well tolerated but expensive
Virazole (Ribavirin)	Treatment of severe lower respiratory tract infection with RSV, usually reserved for ventilated clients	Administer via aerosol with the small-particle aerosol generator (SPAG). Suction patients on assisted ventilation every 2 hours; monitor pulmonary pressures every 2 to 4 hours. May cause blurred vision and photosensitivity.
Corticosteroids (inhaled)	Exert a potent, locally acting anti-inflammatory effect to decrease the frequency and severity of asthma attacks. May also delay pulmonary damage that occurs with chronic asthma. Also used for chronic lung disease and croup syndromes.	Not for treatment of acute wheezing Rinse mouth after inhalation to decrease incidence of fungal infections, dry mouth, and hoarseness. Minimal systemic absorption makes inhaled steroids the treatment of choice for asthma maintenance program.

Medication	Action/Indications	Nursing Implications
Corticosteroids (oral, parenteral)	Suppress inflammation and normal immune response Used for acute asthma exacerbations, wheezing with chronic lung disease, and severe croup	May cause hyperglycemia May suppress reaction to allergy tests Consult physician if vaccinations are ordered during course of systemic corticosteroid therapy. Short courses of therapy are generally safe. Very effective, but long-term or chronic use can result in peptic ulceration, altered growth, and numerous other side effects. Children on long-term dosing should have growth assessed.
Decongestants (e.g., pseudephedrine)	Treatment of runny or stuffy nose associated with the common cold, sinusitis, or allergic rhinitis in children over age 6	Assess child periodically for nasal congestion. Some children react to decongestants with excessive sleepiness or increased activity.
Leukotriene receptor antagonists (montelukast, zafirlukast, zileuton)	Decrease inflammatory response by antagonizing the effects of leukotrienes to control asthma in children age 1 year and older Montelukast: for allergic rhinitis in children 6 months and older	Given once daily, in the evening Not for relief of bronchospasm during an acute wheezing episode, but may be continued during the episode
Mast-cell stabilizers (cromolyn, nedocromil)	Prevent release of histamine from sensitized mast cells, resulting in decreased frequency and intensity of allergic reactions in children with asthma or chronic lung disease. Also used as pre-exposure treatment for allergens.	Administered via inhalation For prophylactic use, not to relieve bronchospasm during an acute wheezing episode. Can be used 10 to 15 minutes prior to exposure to allergen, to decrease reaction to allergen.
Methylxanthines (theophylline, aminophylline)	To provide for continuous airway relaxation in moderate or severe asthma in order to achieve long-term control Also indicated for apnea of prematurity (see "Caffeine")	Administered orally or intravenously. Sustained-release oral preparation can be used to prevent nocturnal symptoms. Monitor drug levels routinely. Report signs of toxicity immediately: tachycardia, nausea, vomiting, diarrhea, stomach cramps, anorexia, confusion, headache, restlessness, flushing, increased urination, seizures, arrhythmias, insomnia.
Caffeine	Stimulates the respiratory center in infants with apnea of prematurity	See "Methylxanthines."
Pulmozyme (dornase alfa)	Enzyme that hydrolyzes the DNA in sputum, reducing sputum viscosity in children with cystic fibrosis	Administered via nebulizer Monitor for dysphonia and pharyngitis.
Synagis (palivizumab)	Monoclonal antibody used to prevent serious lower respiratory RSV disease in certain high-risk groups of children	Should be administered monthly during the RSV season Given intramuscularly only

HEALTHY PEOPLE 2010

Objective	Significance
Reduce the proportion of children who are regularly exposed to tobacco smoke at home.	• Educate the family about the effects that passive smoking has on children. • Encourage families to join smoking cessation programs.

tonsil size and status, and presence of lesions anywhere in the oral cavity.

Cough and Other Airway Noises. Note the sound of the cough. (Is it wet, productive, dry and hacking, tight? When does the cough occur? Is it only or mainly at night?) If noises associated with breathing are present (grunting, stridor, or audible wheeze) these should also be noted. Grunting occurs on **expiration** and is produced by prema-

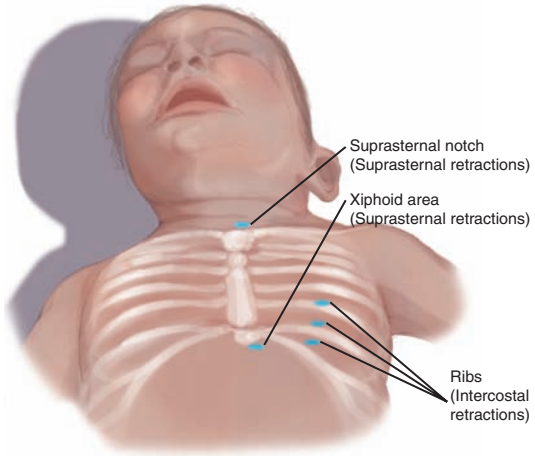

FIGURE 39.3 Location of retractions.

ture glottic closure. It is an attempt to preserve or increase functional residual capacity. Grunting might occur with alveolar collapse or loss of lung volume, such as in atelectasis, pneumonia, and pulmonary edema. **Stridor**, a high-pitched, readily audible inspiratory noise, is a sign of upper airway obstruction. Sometimes wheezes can be heard with the naked ear; these are referred to as audible wheezes.

Respiratory Effort. Assess respiratory effort for depth and quality. Is breathing labored? Infants and children with significant nasal congestion may have tachypnea, which usually resolves when the nose is cleared of mucus. Mouth breathing also may occur when a large amount of nasal congestion is present. Increased work of breathing, particularly if associated with restlessness and anxiety, usually indicates lower respiratory involvement. Assess for the presence of nasal flaring, retractions, or head bobbing. Nasal flaring can occur early in the course of respiratory illness and is an effort to inhale greater amounts of oxygen.

Retractions (the inward pulling of soft tissues with respiration) can occur in the intercostal, subcostal, substernal, supraclavicular, or suprasternal regions (Fig. 39.3). Document the severity of the retractions: mild, moderate, or severe. Also note the use of accessory neck muscles. Note the presence of paradoxical breathing (lack of simultaneous chest and abdominal rise with the inspiratory phase; Fig. 39.4). Bobbing of the head with each breath is also a sign of increased respiratory effort.

▶ ***Take*** *NOTE!*

Seesaw (or paradoxical) respirations are very ineffective for ventilation and oxygenation. The chest falls on inspiration and rises on expiration.

Anxiety and Restlessness. Is the child anxious or restless? Restlessness, irritability, and anxiety result from difficulty in securing adequate oxygen. These might be very early signs of respiratory distress, especially if accompanied by tachypnea. Restlessness might progress to listlessness and lethargy if the respiratory dysfunction is not corrected.

Clubbing. Inspect the fingertips for the presence of **clubbing**, an enlargement of the terminal phalanx of the finger, resulting in a change in the angle of the nail to the fingertip (Fig. 39.5). Clubbing might occur in children with a chronic respiratory illness. It is the result of increased capillary growth as the body attempts to supply more oxygen to distal body cells.

Hydration Status. Note the child's hydration status. The child with a respiratory illness is at risk for dehydration. Pain related to sore throat or mouth lesions may prevent the child from drinking properly. Nasal congestion interferes with the infant's ability to suck effectively at the breast or bottle. Tachypnea and increased work of breathing interfere with the ability to safely ingest fluids.

Assess the oral mucosa for color and moisture. Note skin turgor, presence of tears, and adequacy of urine output.

Auscultation

Assess lung sounds via auscultation. Evaluate breath sounds over the anterior and posterior chest, as well as in the axillary areas. Note the adequacy of aeration. Breath sounds should be equal bilaterally. The intensity and pitch should be equal throughout the lungs; document diminished breath sounds. In the absence of concurrent lower respiratory illness, the breath sounds should be clear throughout all lung fields. During normal respiration, the inspiratory phase is usually softer and longer than the expiratory phase. Prolonged expiration is a sign of bronchial

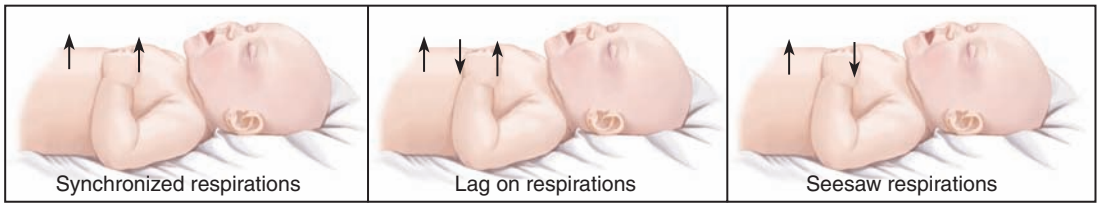

FIGURE 39.4 Seesaw respirations.

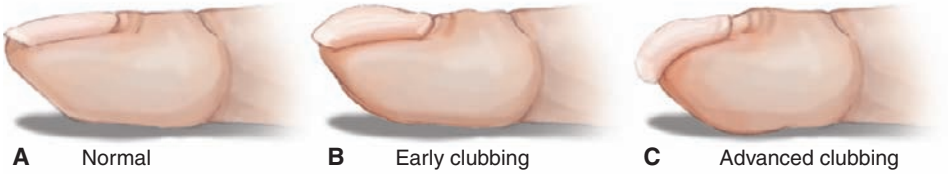

FIGURE 39.5 (**A**) Normal fingertip. Early clubbing (**B**) may progress eventually to advanced clubbing (**C**) as a result of chronic hypoxemia.

or bronchiolar obstruction. Bronchiolitis, asthma, pulmonary edema, and an intrathoracic foreign body can cause prolonged expiratory phases.

Infants and young children have thin chest walls. When the upper airway is congested (as in a severe cold), the noise produced in the upper airway might be transmitted throughout the lung fields. When upper airway congestion is transmitted to the lung fields, the congested-sounding noise heard over the trachea is the same type of noise heard over the lungs but is much louder and more intense. To ascertain if these sounds are truly adventitious lung sounds or if they are transmitted from the upper airway, auscultate again after the child coughs or his or her nose has been suctioned. Another way to discern the difference is to compare auscultatory findings over the trachea to the lung fields to determine if the abnormal sound is truly from within the lung or is actually a sound transmitted from the upper airway.

Note adventitious sounds heard on auscultation. Wheezing, a high-pitched sound that usually occurs on expiration, results from obstruction in the lower trachea or bronchioles. Wheezing that clears with coughing is most likely a result of secretions in the lower trachea. Wheezing resulting from obstruction of the bronchioles, as in bronchiolitis, asthma, chronic lung disease, or cystic fibrosis, does not clear with coughing. **Rales** (crackling sounds) result when the alveoli become fluid-filled, such as in pneumonia. Note the location of the adventitious sounds as well as the timing (on inspiration, expiration, or both). Tachycardia might also be present. An increase in heart rate often initially accompanies hypoxemia.

Percussion

When percussing, note sounds that are not resonant in nature. Flat or dull sounds might be percussed over partially consolidated lung tissue, as in pneumonia. Tympany might be percussed with a pneumothorax. Note the presence of hyperresonance (as might be apparent with asthma).

Palpation

Palpate the sinuses for tenderness in the older child. Assess for enlargement or tenderness of the lymph nodes of the head and neck. Document alterations in tactile fremitus detected on palpation. Increased tactile fremitus might occur in a case of pneumonia or pleural effusion. Fremitus might be decreased in the case of barrel chest, as with cystic fibrosis. Absent fremitus might be noted with pneumothorax or atelectasis.

Compare central and peripheral pulses. Note the quality of the pulse as well as the rate. With significant respiratory distress, perfusion often becomes compromised. Poor perfusion might be reflected in weaker peripheral pulses (radial, pedal) when compared to central pulses.

Laboratory and Diagnostic Testing

Common Laboratory and Diagnostic Tests 39.1 explains the laboratory and diagnostic tests most commonly used for a child with a respiratory disorder. The tests can assist the physician in diagnosing the disorder and/or be used as guidelines in determining ongoing treatment. Laboratory or non-nursing personnel obtain some of the tests, while the nurse might obtain others. In either instance the nurse should be familiar with how the tests are obtained, what they are used for, and normal versus abnormal results. This knowledge will also be necessary when providing client and family education related to the testing.

▶ ***Take*** NOTE!

Ambient light may interfere with pulse oximetry readings. When the pulse oximeter probe is placed on the infant's foot or the young child's toe, covering the probe and foot with a sock may help to ensure an accurate measurement.

Nursing Diagnoses, Goals, Interventions, and Evaluation

Upon completion of a thorough assessment, the nurse might identify several nursing diagnoses, including:

- Ineffective Airway Clearance
- Ineffective Breathing Pattern
- Impaired Gas Exchange
- Risk for Infection
- Pain
- Risk for Fluid Volume Deficit
- Altered Nutrition, less than body requirements
- Activity Intolerance
- Fear
- Altered Family Processes

(text continues on page 1230)

COMMON LABORATORY AND DIAGNOSTIC TESTS 39.1 Respiratory Disorders

Test	Explanation	Indications	Nursing Implications
Allergy skin testing	Suggested allergen is applied to skin via scratch, pin, or prick. A wheal response indicates allergy to the substance. Carries risk of anaphylaxis. (Nursing note: Antihistamines must be discontinued before testing, as they inhibit the test.)	Allergic rhinitis, asthma	Close observation for anaphylaxis is necessary. Epinephrine and emergency equipment should be readily available. Some children react to the skin test almost immediately; others take several minutes.
Arterial blood gases	Invasive method (requires blood sampling) of measuring arterial pH, partial pressure of oxygen and carbon dioxide, and base excess in blood	Usually reserved for severe illness, the intubated child, or suspected carbon dioxide retention	Hold pressure for several minutes after a peripheral arterial stick to avoid bleeding. Radial arterial sticks are common and can be very painful. Note if the child is crying excessively during the blood draw, as this affects the carbon dioxide level.
Chest x-ray	Radiographic image of the expanded lungs: can show hyperinflation, atelectasis, pneumonia, foreign body, pleural effusion, abnormal heart or lung size	Bronchiolitis, pneumonia, tuberculosis, asthma, cystic fibrosis, bronchopulmonary dysplasia	Children may be afraid of the x-ray equipment. If a parent or familiar adult can accompany the child, often the child is less afraid. If the child is unable or unwilling to hold still for the x-ray, restraint may be necessary. Restraint should be limited to the amount of time needed for the x-ray.
Fluorescent antibody testing	Determines presence of respiratory syncytial virus (RSV), adenovirus, influenza, parainfluenza, or *Chlamydia* in nasopharyngeal secretions	Bronchiolitis, pneumonia	To obtain a nasopharyngeal specimen, instill 1 to 3 mL of sterile normal saline into one nostril, aspirate the contents using a small sterile bulb syringe, place the contents in sterile container, and immediately send them to the lab.
Fluoroscopy	Radiographic examination that uses a fluorescent screen— "real-time" imaging	Identification of masses, abscesses	Requires the child to lie still. Equipment can be frightening. Children may respond to presence of parent or familiar adult.
Gastric washings for AFB	Determines presence of AFB (acid-fast bacilli) in stomach (children often swallow sputum)	Tuberculosis	Nasogastric tube is inserted and saline is instilled and suctioned out of the stomach to obtain the specimen.
Peak expiratory flow	Measures the maximum flow of air (in L/sec) that can be forcefully exhaled in 1 second	Daily use can indicate adequacy of asthma control.	It is important to establish the child's "personal best" by taking twice-daily readings over a 2-week period while well. The average of these is termed "personal best." Charts based on height and age are also available to determine expected peak expiratory flow.

Test	Explanation	Indications	Nursing Implications
Pulmonary function tests	Measure respiratory flow and lung volumes	Asthma, cystic fibrosis, chronic lung disease	Usually performed by a respiratory therapist trained to do the full spectrum of tests. Spirometry can be obtained by the trained nurse in the outpatient setting.
Pulse oximetry	Noninvasive method of continuously (or intermittently) measuring oxygen saturation	Can be useful in any situation in which a child is experiencing respiratory distress	Probe must be applied correctly to finger, toe, foot, hand, or ear in order for the machine to appropriately pick up the pulse and oxygen saturation.
Rapid flu test	Rapid test for detection of influenza A or B	Influenza	Should be done in first 24 hours of illness so that medication administration can begin Have the child gargle with sterile normal saline and then spit into a sterile container. Send immediately to the lab.
Rapid strep test	Instant test for presence of strep A antibody in pharyngeal secretions	Pharyngitis, tonsillitis	Results in 5 to 10 minutes. Negative tests should be backed up with throat culture.
RAST (radioallergosorbent test)	Measures minute quantities of immunoglobulin E in the blood Carries no risk of anaphylaxis but is not as sensitive as skin testing	Asthma (food allergies)	Blood test that is usually sent out to a reference laboratory
Sinus x-rays, computed tomography (CT), or magnetic resonance imaging (MRI)	Radiologic tests that may show sinus involvement	Sinusitis, recurrent colds	X-ray results are usually received more quickly than CT or MRI results.
Sputum culture	Bacterial culture of invasive organisms in the sputum	Pneumonia, cystic fibrosis, tuberculosis	Must be true sputum, not mucus from the mouth or nose. Child can deep breathe, cough, and spit, or specimen may be obtained via suctioning of the artificial airway.
Sweat chloride test	Collection of sweat on filter paper after stimulation of skin with pilocarpine Measures concentration of chloride in the sweat	Cystic fibrosis	May be difficult to obtain sweat in a young infant
Throat culture	Bacterial culture (minimum of 24 to 48 hours required) to determine presence of streptococcus A or other bacteria	Pharyngitis, tonsillitis	Can be obtained on separate swab at same time as rapid strep test to decrease trauma to the child (swab both applicators at once) Do not perform immediately after the child has had medication or something to eat or drink.
Tuberculin skin test	Mantoux test (intradermal injection of purified protein derivative)	Tuberculosis, chronic cough	Must be given intradermally; not a valid test if injected incorrectly

After completing an assessment of Alexander, the nurse notes the following: lots of clear secretions in the airway, child appears pale, respiratory rate 68, retractions, nasal flaring, wheezing, and diminished breath sounds. Based on these assessment findings, what would your top three nursing diagnoses be for Alexander?

Nursing goals, interventions, and evaluation for the child with a respiratory disorder are based on the nursing diagnoses. Nursing Care Plan 39.1 can be used as a guide in planning nursing care for the child with a respiratory disorder. The nursing care plan should be individualized based on the client's symptoms and needs; refer to Chapter 35 for detailed information on pain management. Additional information will be included later in the chapter as it relates to specific disorders.

Based on your top three nursing diagnoses for Alexander, describe appropriate nursing interventions.

Oxygen Supplementation

Oxygen may be delivered to the child by a variety of methods (Fig. 39.6). Since oxygen administration is considered a drug, it requires a physician's order, except when following emergency protocols outlined in a health care facility's policies and procedures. Many health care settings develop specific guidelines for oxygen administration that are often coordinated by respiratory therapists, yet the nurse still remains responsible for ensuring that oxygen is administered properly.

Oxygen sources include wall-mounted systems as well as cylinders. The supply of oxygen available from a wall-mounted source is limitless, but use of a wall-mounted source restricts the child to the hospital room. Cylinders are portable oxygen tanks; the D-cylinder holds a little less than 400 liters of oxygen and the E-cylinder holds about 650 liters of oxygen. Cylinders turn on with a gauge attached to the top of the tank. The cylinder is useful for the child on low-flow oxygen because it allows for mobility.

The tank empties relatively quickly if the child requires a high flow of oxygen, so this is not the best oxygen source in an emergency. Respiratory therapists usually maintain the respiratory equipment that is found in the emergency room or hospital. However, in an outpatient setting the nurse may be responsible for maintaining respiratory equipment and checking the level of oxygen in the office's oxygen tanks each day.

▶ *Take* NOTE!

Oxygen is highly flammable, so use safety precautions. Post signs ("Oxygen in Use"); inform the family to avoid matches, lighters, and flammable or volatile materials; and use only facility-approved equipment.

The efficiency of oxygen delivery systems is affected by several variables, including the child's respiratory effort, the liter flow of oxygen delivered, and whether the equipment is being used appropriately. In general, oxygen facemasks come in infant, child, and adult sizes. Select the mask that best fits the child. In addition, ensure that the mask is sealed properly to decrease the amount of oxygen that escapes from the mask. Ensure that the liter flow is set according to the manufacturer's recommendations for use with that particular delivery method. The oxygen flow rate or concentration is usually determined by the physician's order. Whichever method of delivery is used, provide humidification during oxygen delivery to prevent drying of nasal passages and to assist with liquefying secretions. Table 39.1 provides details on oxygen delivery methods.

▶ *Take* NOTE!

Monitor vital signs, color, respiratory effort, pulse oximetry, and level of consciousness before, during, and after oxygen therapy to evaluate its effectiveness.

Acute Infectious Disorders

Acute infectious disorders include the common cold, sinusitis, influenza, pharyngitis, tonsillitis, laryngitis, croup syndromes, respiratory syncytial virus (RSV), pneumonia, and bronchitis.

COMMON COLD

The common cold is also referred to as a viral upper respiratory infection (URI) or nasopharyngitis. Colds can be caused by a number of different viruses, including rhinoviruses, parainfluenza, RSV, enteroviruses, and adenoviruses (National Institute of Allergy and Infectious Diseases, 2007). Recently, human meta-pneumovirus has been identified as an important cause of the common cold (Burke, 2004). Viral particles spread through the air or from person-to-person contact. Colds occur more frequently in winter. They affect children of all ages and have a higher incidence among children who attend daycare and school-age children. It is not unusual for a child to have six to nine colds per year. Spontaneous resolution of the common cold occurs after about 7 to 10 days. Potential complications include secondary bacterial infections of the ears, throat, sinuses, or lungs.

Therapeutic management of the common cold is directed toward symptom relief. Nasal congestion may

(text continues on page 1234)

Nursing Care Plan 39.1

Overview for the Child With a Respiratory Disorder

NURSING DIAGNOSIS: Ineffective airway clearance related to inflammation, increased secretions, mechanical obstruction, or pain as evidenced by presence of secretions, productive cough, tachypnea, and increased work of breathing

Outcome Identification and Evaluation

Child will maintain patent airway, *free from secretions or obstruction, easy work of breathing, respiratory rate within parameters for age.*

Interventions: Maintaining a Patent Airway

- Position with airway open (sniffing position if supine) *to allow adequate ventilation.*
- Humidify oxygen or room air and ensure adequate fluid intake (intravenous or oral) *to liquefy secretions for ease in clearance.*
- Suction with bulb syringe or via nasopharyngeal catheter as needed, particularly prior to bottle-feeding, *to promote clearance of secretions.*
- If tachypneic, maintain NPO status *to avoid aspiration.*
- In older child, encourage expectoration of sputum with coughing *to promote airway clearance.*
- Perform chest physiotherapy if ordered *to mobilize secretions.*
- Ensure emergency equipment is readily available *to avoid delay should airway become unmaintainable.*

NURSING DIAGNOSIS: Ineffective breathing pattern related to inflammatory or infectious process as evidenced by tachypnea, increased work of breathing, nasal flaring, retractions, diminished breath sounds

Outcome Identification and Evaluation

Child will exhibit adequate ventilation: *respiratory rate within parameters for age, easy work of breathing (absence of retractions, accessory muscle use, grunting), clear breath sounds with adequate aeration, oxygen saturation >94% or within prescribed parameters.*

Interventions: Promoting Effective Breathing Patterns

- Assess respiratory rate, breath sounds, and work of breathing frequently *to ensure progress with treatment and so that deterioration can be noted early.*
- Use pulse oximetry to monitor oxygen saturation in the least invasive manner *to note adequacy of oxygenation and ensure early detection of hypoxemia.*
- Position for comfort with open airway and room for lung expansion. Use pillows or padding if necessary to maintain position *to ensure optimal ventilation via maximum lung expansion.*
- Administer supplemental oxygen and/or humidity as ordered *to improve oxygenation.*
- Allow for adequate sleep and rest periods *to conserve energy.*
- Administer antibiotics as ordered: *may be indicated in the case of bacterial respiratory infection.*
- Encourage incentive spirometry and coughing with deep breathing (can be accomplished through play) *to maximize ventilation (play enhances the child's participation).*

NURSING DIAGNOSIS: Gas exchange, impaired, related to airway plugging, hyperinflation, atelectasis, as evidenced by cyanosis, decreased oxygen saturation, and alterations in arterial blood gases

Outcome Identification and Evaluation

Gas exchange will be adequate: *Pulse oximetry reading on room air is within normal parameters for age, blood gases within normal limits, absence of cyanosis.*

Interventions: Promoting Adequate Gas Exchange

- Administer oxygen as ordered *to improve oxygenation.*
- Monitor oxygen saturation via pulse oximetry *to detect alterations in oxygenation.*
- Encourage clearance of secretions via coughing, expectoration, chest physiotherapy, and suctioning *to improve gas exchange.*
- Administer bronchodilators if ordered (albuterol, levalbuterol, and racemic epinephrine) *to treat bronchospasm and improve gas exchange.*
- Provide frequent contact and support to the child and family *to decrease anxiety, which increases the child's oxygen demands.*
- Assess and monitor mental status (confusion, lethargy, restlessness, combativeness): *hypoxemia can lead to changes in mental status.*

(continued)

Nursing Care Plan 39.1 (continued)

NURSING DIAGNOSIS: Risk for infection related to presence of infectious organisms as evidenced by fever or presence of virus or bacteria on laboratory screening

Outcome Identification and Evaluation

Child will exhibit no signs of secondary infection and will not spread infection to others: *symptoms of infection decrease over time; others remain free from infection.*

Interventions: Preventing Infection

- Maintain aseptic technique, practice good handwashing, and use disposable suction catheters *to prevent introduction of further infectious agents.*
- Limit number of visitors and screen them for recent illness *to prevent further infection.*
- Administer antibiotics if prescribed *to prevent or treat bacterial infection.*
- Encourage nutritious diet according to child's preferences and ability to feed orally *to assist body's natural infection-fighting mechanisms.*
- Isolate the child as required *to prevent nosocomial spread of infection.*
- Teach child and family preventive measures such as good handwashing, covering mouth and nose when coughing or sneezing, proper disposal of used tissues *to prevent nosocomial or community spread of infection.*

NURSING DIAGNOSIS: Fluid volume deficit, risk for, related to decreased oral intake, insensible losses via fever, tachypnea, or diaphoresis

Outcome Identification and Evaluation

Fluid volume will be maintained: *Oral mucosa moist and pink, skin turgor elastic, urine output at least 1 to 2 mL/kg/hr.*

Interventions: Maintaining Adequate Fluid Volume

- Administer intravenous fluids if ordered *to maintain adequate hydration in NPO state.*
- When allowed oral intake, encourage oral fluids. Popsicles, favorite fluids, and games can be used *to promote intake.*
- Assess for signs of adequate hydration (elastic skin turgor, moist mucosa, adequate urine output).
- Monitor intake and output *to identify fluid imbalance.*
- Monitor urine specific gravity, urine and serum electrolytes, blood urea nitrogen, creatinine, and osmolality *to determine fluid status.*

NURSING DIAGNOSIS: Nutrition, altered: less than body requirements related to difficulty feeding as evidenced by poor oral intake, tiring with feeding

Outcome Identification and Evaluation

Child will maintain adequate nutritional intake: *Weight is gained or maintained. Child consumes adequate diet for age.*

Interventions: Promoting Adequate Nutritional Intake

- Weigh on same scale at same time daily *so that measurements are consistent.*
- Perform calorie counts over a 3-day period *to determine whether caloric intake is sufficient.*
- Encourage child to choose higher-calorie, protein-rich foods *to optimize growth potential.*
- Coax young children to eat better by playing games and offering favorite foods *to improve intake.*

NURSING DIAGNOSIS: Activity intolerance related to high respiratory demand as evidenced by increased work of breathing and need for frequent rest when playing

Outcome Identification and Evaluation

Child will resume normal activity level: *Activity is tolerated without difficulty breathing. Pulse oximetry readings and vital signs are within parameters for age and activity level.*

Interventions: Increasing Activity Tolerance

- Provide rest periods balanced with periods of activity, and group nursing activities and visits *to allow for sufficient rest.*
- Provide small, frequent meals *to prevent overtiring (energy is expended while eating).*
- Encourage quiet activities that do not require exertion *to prevent boredom.*
- Allow gradual increase in activity as tolerated, keeping pulse oximetry reading within normal parameters, *to minimize risk for further respiratory compromise.*

Nursing Care Plan 39.1 (continued)

NURSING DIAGNOSIS: Fear related to difficulty breathing, unfamiliar personnel, procedures, and environment (hospital), as evidenced by clinging, crying, fussing, verbalization, or lack of cooperation

Outcome Identification and Evaluation

Fear/anxiety will be reduced: *decreased episodes of crying or fussing, happy and playful at times.*

Interventions: Relieving Fear

- Establish trusting relationship with child and family *to decrease anxiety and fear.*
- Explain procedures to child at developmentally appropriate level *to decrease fear of unknown.*
- Provide favorite blanket or bear as well as comfort measures preferred by client such as rocking or music *for added security.*
- Involve parents in care *to give child reassurance and decrease fear.*

NURSING DIAGNOSIS: Family processes, altered, related to child's illness or hospitalization as evidenced by family's presence in hospital, missed work, demonstration of inadequate coping

Outcome Identification and Evaluation

Parents demonstrate adequate coping and decreased anxiety: *Parents are involved in child's care, ask appropriate questions, and are able to discuss child's care and condition calmly.*

Interventions: Promoting Adequate Family Processes

- Encourage parents to discuss their concerns related to child's illness *to identify concerns and show parents that the nurse also cares about them, not just the child.*
- Explain therapy, procedures, and child's behavior to parents *to decrease their anxiety.*
- Encourage parents to be involved in care *so they feel needed and valued.*

FIGURE 39.6 (**A**) Simple oxygen mask provides about 40% oxygen. (**B**) The nasal cannula provides an additional 4% oxygen per 1 L of oxygen flow (i.e., 1 L will deliver 25% oxygen). (**C**) The nonrebreather mask provides 80% to 100% oxygen.

TABLE 39.1 Oxygen Delivery Methods

Delivery Method	Description	Nursing Implications
Simple mask	Provides 35% to 60% oxygen with a flow rate of 6 to 10 L/minute. Oxygen delivery percentage is affected by respiratory rate, inspiratory flow, and adequacy of mask fit.	• Must maintain oxygen flow rate of at least 6 L/minute to maintain inspired oxygen concentration and prevent rebreathing of carbon dioxide • Mask must fit snugly to be effective but should not be so tight as to irritate the face.
Venturi mask	Provides 24% to 50% oxygen by using a special gauge at the base of the mask that allows mixing of room air with oxygen flow	• Set oxygen flow rate according to percentage of oxygen desired as indicated on the gauge/dial. • As with simple mask, must fit snugly.
Nasal cannula	Provides low oxygen concentration (22% to 44%)	• Must be used with humidification to prevent drying and irritation of airways • Can provide very small amounts of oxygen (as low as 25 cc/minute) • Maximum recommended liter flow in children is 4 L/minute. • Children can eat or talk while on oxygen. • Inspired oxygen concentration affected by mouth breathing • Requires patent nasal passages
Oxygen tent	Provides high-humidity environment with up to 50% oxygen concentration	• Oxygen level drops when tent is opened. • Must change linen frequently as it becomes damp from the humidity • Secure edges of tent with blankets or by tucking edges under mattress. • Young children may be fearful and resistant. • Mist may interfere with visualization of child inside tent.
Oxygen hood	Provides high concentration (up to 80% to 90%) for infants only. Allows easy access to chest and lower body.	• Liter flow must be set at 10 to 15 L/minute. • Good method for infant but need to remove for feeding • Can and should be humidified
Partial rebreathing mask	Simple facemask with an oxygen reservoir bag. Provides 50% to 60% oxygen concentration.	• Must set liter flow rate at 10 to 12 L/min to prevent rebreathing of carbon dioxide • The reservoir bag does not completely empty when child inspires if flow rate is set properly.
Nonrebreathing mask	Simple facemask with valves at the exhalation ports and an oxygen reservoir bag with a valve to prevent exhaled air from entering the reservoir. Provides 95% oxygen concentration.	• Must set liter flow rate at 10 to 12 L/min to prevent rebreathing of carbon dioxide • The reservoir bag does not completely empty when child inspires if flow rate is set properly.

be relieved via humidity and use of normal saline nasal wash or spray followed by suctioning. Antihistamines are not indicated, as they dry secretions further. Over-the-counter cold preparations are available singly and in combinations. These preparations have not been proven to reduce the length or severity of the cold but may offer symptomatic relief in some children over 6 years of age.

▶ **Take** NOTE!

In October 2007, over-the-counter cold preparations containing decongestants intended for use in infants and young children were removed from the market. Several research studies have not shown the preparations to be effective, and they are known to have potentially serious side effects (AAP, 2007).

EVIDENCE-BASED PRACTICE 39.1
Various Body Positions and Their Effects on Hospitalized Infants and Young Children With Acute Respiratory Distress

● Study
Prone positioning has been found to improve ventilation in some adults with acute respiratory distress and in premature infants with respiratory distress syndrome, but due to the risk of sudden infant death syndrome (SIDS), infants are generally positioned supine. The authors reviewed 21 studies that evaluated the effect of positioning (supine, prone, lateral, elevated, and flat positions) on respiratory function (oxygen saturation, partial pressure of arterial oxygen, oxygenation index, thoraco-abdominal synchrony, and episodes of oxygen desaturation) in infants and young children with acute respiratory distress.

▲ Findings
The only position found to produce a statistically significant improvement in respiratory function was the prone position. The prone position was better in terms of improving ventilation and oxygenation. The other positions did not demonstrate statistically significant differences.

■ Nursing Implications
Nurses should critically consider the result of this review. Certainly, if an alternate position is used, the infant must be closely monitored and the position changed should any level of deterioration occur. If hospitalized infants with acute respiratory distress are placed in the prone position, continuous cardiopulmonary and oxygenation saturation monitoring must be provided because of the risk of SIDS in this age group. Do not encourage families to use the prone position at home when an infant is ill with a respiratory condition.

Wells, D. A., Gillies, D., & Fitzgerald, D. A. (2007). Positioning for acute respiratory distress in hospitalised infants and children. *The Cochrane Library 2007, 4.* Indianapolis: John Wiley & Sons.

Nursing Assessment

The child may have either a stuffy or runny nose. Nasal discharge is usually thin and watery at first but may become thicker and discolored. The color of nasal discharge is not an accurate indicator of viral versus bacterial infection. The child may be hoarse and complain of a sore throat. Cough usually produces very little sputum. Fever, fatigue, watery eyes, and appetite loss may also occur. Symptoms are generally at their worst over the first few days and then decrease over the course of the illness.

Assess for risk factors such as daycare or school attendance. Inspect for edema and vasodilation of the mucosa. Diagnosis is based on clinical presentation rather than laboratory or x-ray studies. Comparison Chart 39.1 differentiates causes of nasal congestion.

Nursing Management

Nursing management of the child with a common cold consists of promoting comfort, providing family education, and preventing spread of the cold.

COMPARISON CHART 39.1 Causes of Nasal Congestion

Sign or Symptom	Allergic Rhinitis	Common Cold	Sinusitis
Length of illness	Varies; may have year-round symptoms	10 days or less	Longer than 10 to 14 days
Nasal discharge	Thin, watery, clear	Thick, white, yellow, or green; can be thin	Thick, yellow or green
Nasal congestion	Varies	Present	Present
Sneezing	Varies	Present	Absent
Cough	Varies	Present	Varies
Headache	Varies	Varies	Varies
Fever	Absent	Varies	Varies
Bad breath	Absent	Absent	Varies

Promoting Comfort

Nursing care of the common cold is aimed at supportive measures. Nasal congestion may be relieved with the use of normal saline nose drops, followed by bulb syringe suctioning in infants and toddlers. Older children may use a normal saline nose spray to mobilize secretions. A cool mist humidifier also helps with nasal congestion. Generally, other over-the-counter nose sprays are not recommended for use in children, but they are sometimes prescribed for very short-term use. Promotion of adequate oral fluid intake is important to liquefy secretions.

Educate parents about the use of cold and cough medications. Although they may offer some symptomatic relief, they have not been proven to shorten the length of cold symptoms. Counsel parents to use the appropriate product depending on the symptom relief desired, rather than a combination product. Products containing acetaminophen combined with other "cold symptom" medications may mask a fever in the child who is developing a secondary bacterial infection. As with all viral infections in children, teach parents that aspirin use should be avoided because of its association with Reye syndrome.

Providing Family Education

Currently there are no medications available to treat the viruses that cause the common cold, so symptomatic treatment is all that is necessary. Antibiotics are not indicated unless the child also has a bacterial infection. Explain to parents the importance of reserving antibiotic use for appropriate illnesses. Provide education about the use of normal saline nose drops and bulb suctioning to clear the infant's nose of secretions. Normal saline nasal wash using a bulb syringe to instill the solution is also helpful for children of all ages with nasal congestion. Though normal saline for nasal administration is available commercially, parents can also make it at home (Box 39.2). Teaching Guidelines 39.1 gives instructions on use of the bulb syringe.

Counsel parents about how to recognize complications of the common cold. These include:

- Prolonged fever
- Increased throat pain or enlarged, painful lymph nodes
- Increased or worsening cough, cough lasting longer than 10 days, chest pain, difficulty breathing
- Earache, headache, tooth or sinus pain
- Unusual irritability or lethargy
- Skin rash

If complications do occur, tell parents to notify the health care provider for further instructions or reassessment.

BOX 39.2 Homemade Salt Water Nose Drops

Mix 8 oz distilled water, a half-teaspoon sea salt, and a quarter-teaspoon baking soda. Keeps for 24 hours in the refrigerator, but should be allowed to come to room temperature prior to use.

Preventing the Common Cold

Teaching about ways to prevent the common cold is a vital nursing intervention. Explain that frequent handwashing helps to decrease the spread of viruses that cause the common cold. Teach parents and family to avoid second-hand smoke as well as crowded places, especially during the winter. Avoid close contact with individuals known to have a cold. Encourage parents and families to consume a healthy diet and get enough rest.

▸ *Consider* THIS!

Corey Davis, a 3-year-old, is brought to the clinic by her mother. She presents with a runny nose, congestion, and a nonproductive cough. Her mother says, "She's miserable."

What other assessment information would be helpful?

Based on the history and clinical presentation, Corey is diagnosed with a common cold. What education would be helpful for this family? Include ways to improve Corey's comfort and ways to prevent the common cold.

SINUSITIS

Sinusitis (also called rhinosinusitis) generally refers to a bacterial infection of the paranasal sinuses. The disease may be either acute or chronic in nature, with the treatment approach varying with chronicity. Approximately 5% of upper respiratory infections are complicated with acute sinusitis. In young children the maxillary and ethmoid sinuses are the main sites of infection. After age 10 years, the frontal sinuses may be more commonly involved. Mucosal swelling, decreased ciliary movement, and thickened nasal discharge all contribute to bacterial invasion of the nose. Nasal polyps also place the child at risk for bacterial sinusitis. Complications include orbital cellulitis and intracranial infections such as subdural empyemas.

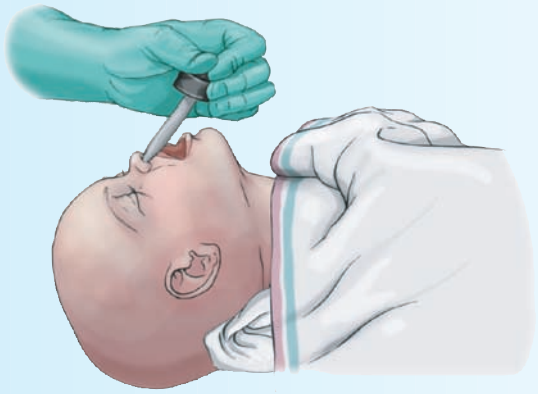
Symptoms lasting less than 30 days generally indicate acute sinusitis, whereas symptoms persisting longer than 4 to 6 weeks usually indicate chronic sinusitis. Sinusitis is managed with antibiotic treatment. The course of treatment is a minimum of 10 days. The current American Academy of Pediatrics recommendations state that antibiotics should be continued for 7 days once the child is free from symptoms to eradicate the infection (AAP, 2001).

TEACHING GUIDELINES 39.1

Using the Bulb Syringe to Suction Nasal Secretions

1. Hold the infant on your lap or on the bed with head tilted slightly back.

2. If using saline, instill several drops of saline solution in one of infant's nostrils.



3. Compress the sides of the bulb syringe completely. Use only a rubber-tipped bulb syringe. Place the rubber tip in the infant's nose.

4. Release pressure on the bulb.

5. Remove the syringe and squeeze bulb over tissue or the sink to empty it of secretions.

6. Repeat on other nostril if necessary. Using a bulb syringe prior to bottle-feeding or breastfeeding may relieve congestion enough to allow the infant to suck more efficiently.
7. Clean the bulb syringe thoroughly with warm water after each use and allow to air dry.

HEALTHY PEOPLE 2010

Objective	Significance
Reduce the number of courses of antibiotics prescribed for the sole diagnosis of the common cold.	• Appropriately educate families that the cause of the common cold is a number of viruses and that antibiotics are inappropriate for the treatment of viral infections. • Encourage families to use measures such as normal saline nasal washes to decrease symptoms associated with the common cold more quickly.

Naturally, chronic sinusitis requires a longer course of treatment than acute sinusitis. Surgical therapy may be indicated for children with chronic sinusitis, particularly if it is recurrent or if nasal polyps are present.

Nursing Assessment

The most common presentation of sinusitis is persistent signs and symptoms of a cold. Rather than improving after 7 to 10 days, nasal discharge persists. Explore the history for:

- Cough
- Fever
- In preschoolers or older children, halitosis (bad breath)
- Facial pain may or may not be present, so is not a reliable indicator of disease.
- Eyelid edema (in the case of ethmoid sinus involvement)
- Irritability
- Poor appetite

Cold symptoms that are severe and not improving over time may also indicate sinusitis (Leung & Kellner, 2004). Assess for risk factors such as a history of recurrent cold symptoms or a history of nasal polyps.

On physical examination, note eyelid swelling, extent of nasal drainage, and halitosis. Inspect the throat for postnasal drainage. Inspect the nasal mucosa for erythema. Palpate the sinuses, noting pain with mild pressure. The diagnosis may be made based on the history and clinical presentation, augmented by x-ray, computed tomography scan, or magnetic resonance imaging findings in some cases (Leung & Kellner, 2004). (Refer to Comparison Chart 39.1, which differentiates the causes of nasal congestion.)

Nursing Management

Normal saline nose drops or spray, cool mist humidifiers, and adequate oral fluid intake are recommended for children with sinusitis. Teach families the importance of continuing the full course of antibiotics to eradicate the cause of infection. Also educate the family that using decongestants, antihistamines, and intranasal steroids as adjuncts in the treatment of sinusitis has not been shown to be beneficial. Normal saline nose spray or nasal washes may promote drainage (Leung & Kellner, 2004).

INFLUENZA

Influenza viral infection occurs primarily during the winter. "The flu" is spread through inhalation of droplets or contact with fine-particle aerosols. Infected children shed the virus for 1 to 2 days before symptoms begin and may continue increased amounts of viral shedding as compared with adults for as long as 2 weeks. Average annual infection rates in children range from 20% to 50% (Iskander et al., 2007). Influenza viruses primarily affect the upper respiratory epithelium but can cause systemic effects as well. Children with chronic heart or lung conditions, diabetes, chronic renal disease, or immune deficiency are at higher risk than other children for more severe influenza infection.

Bacterial infections of the respiratory system commonly occur as complications of influenza infection, severe pneumococcal pneumonia in particular. Otitis media occurs in 18% to 40% of all influenza cases (Iskander et al., 2007). Less common complications include Reye syndrome and acute myositis. Reye syndrome is an acute encephalopathy that has been associated with aspirin use in the influenza-infected child. Acute myositis is particular to children. A sudden onset of severe pain and tenderness in both calves causes the child to refuse to walk. Due to the potential for complications, a prolonged fever or a fever that returns during convalescence should be investigated.

Nursing Assessment

Children who attend daycare or school are at higher risk for influenza infection than those who are routinely at home. Note the presence of risk factors for severe disease, such as chronic heart or lung disease (such as asthma), diabetes, chronic renal disease, or immune deficiency or children with cancer receiving chemotherapy. School-age children and adolescents experience the illness similarly to adults. Abrupt onset of fever, facial flushing, chills, headache, myalgia, and malaise are accompanied by cough and **coryza.** About half of infected individuals have a dry or sore throat. Ocular symptoms such as photophobia, tearing, burning, and eye pain are common.

Infants and young children exhibit symptoms similar to other respiratory illnesses. Fever greater than 39.5°C is common. Infants may be mildly toxic in appearance and irritable and have a cough, coryza, and pharyngitis. Wheezing may occur, as influenza also can cause bronchiolitis. An erythematous rash may be present, and diarrhea

may also occur. The diagnosis may be confirmed by a rapid assay test.

Nursing Management

Nursing management of influenza is mainly supportive. Symptomatic treatment of cough and fever and maintenance of hydration are the focus of care. Amantadine hydrochloride (Symmetrel) and other newer antiviral drugs can reduce the symptoms associated with influenza if started within the first 24 to 48 hours of the illness.

Preventing Influenza Infection

Yearly vaccination against influenza is recommended for high-risk groups. Children 6 months or older are considered high risk if they:

- Have chronic heart or lung conditions
- Have sickle cell anemia or other hemoglobinopathy
- Are under medical care for diabetes, chronic renal disease, or immune deficiency
- Are on long-term aspirin therapy (risk of developing Reye syndrome after the flu)

Among otherwise healthy children, infants and toddlers are at highest risk for developing severe disease. All healthy children between the ages of 6 and 59 months should also be immunized. Refer to Chapter 30 for more information on immunizations.

PHARYNGITIS

Inflammation of the throat mucosa (pharynx) is referred to as **pharyngitis**. A sore throat may accompany nasal congestion and is often viral in nature. A bacterial sore throat most often occurs without nasal symptoms. Group A streptococci account for 15% to 25% of cases, with the remainder being caused by other viruses or bacteria (Martin & Green, 2006).

Suppurative complications of group A streptococcal infection include peritonsillar or retropharyngeal abscess. Peritonsillar abscess may be noted by asymmetric swelling of the tonsils, shifting of the uvula to one side, and palatal edema. Retropharyngeal abscess may progress to the point of airway obstruction, hence requiring careful evaluation and appropriate treatment. Additional complications include acute rheumatic fever (see Chapter 40) and acute glomerulonephritis (see Chapter 42).

Viral pharyngitis is usually self-limited and does not require therapy beyond symptomatic relief. Group A streptococcal pharyngitis requires antibiotic therapy. If either the rapid diagnostic test or throat culture (described below) is positive for group A streptococci, penicillin is generally prescribed. Appropriate alternative antibiotics include amoxicillin and, for those allergic to penicillin, macrolides and cephalosporins (Wong, Blumberg, & Lowe, 2006).

Take NOTE!

A "strep carrier" is a child who has a positive throat culture for streptococci when asymptomatic. Strep carriers are not at risk for complications from streptococci, as are those who are acutely infected with streptococci and are symptomatic.

Nursing Assessment

Onset of the illness is often quite abrupt. The history may include a fever, sore throat and difficulty swallowing, headache, and abdominal pain, which are quite common. Inquire about recent incidence of viral or strep throat in the family, day care center, or school.

Inspect the pharynx and tonsils, which may demonstrate varying degrees of inflammation (Fig. 39.7). Exudate may be present but is not diagnostic of bacterial infection. Note the presence of petechiae on the palate. Inspect the tongue for a strawberry appearance. Palpate for enlargement and tenderness of the anterior cervical nodes. Inspect the skin for a fine, red, sandpaper-like rash (called scarlatiniform), particularly on the trunk or abdomen, a common finding with streptococcus A infection.

The nurse may obtain a throat swab for rapid diagnostic testing and throat culture. If both tests are being obtained, the applicators may be swabbed simultaneously to decrease perceived trauma to the child. The rapid strep test is a sensitive and reliable measure, rarely resulting in

FIGURE 39.7 Note the redness of the pharynx, tonsillar exudate, and white strawberry tongue coating.

false-positive readings (Farrar-Simpson et al., 2005). If the rapid strep test is negative, the second swab may be sent for a throat culture.

Nursing Management

Nursing management of the child with pharyngitis focuses on promoting comfort and providing family education.

Promoting Comfort

Saline gargles (made with 8 oz of warm water and a half-teaspoon of table salt) are soothing for children old enough to cooperate. Analgesics such as acetaminophen and ibuprofen may ease fever and pain. Sucking on throat lozenges or hard candy may also ease pain. Cool mist humidity helps to keep the mucosa moist in the event of mouth breathing. Encourage the child to ingest Popsicles, cool liquids, and ice chips to maintain hydration.

Providing Family Education

Parents may be accustomed to "sore throats" being treated with antibiotics, but in the case of a viral cause antibiotics will not be necessary and the pharyngitis will resolve in a few days. For the child with streptococcal pharyngitis, urge parents to have the child complete the entire prescribed course of antibiotics (Parmet, 2004). After 24 hours of antibiotic therapy, instruct the parents to discard the child's toothbrush to avoid reinfection. Children may return to daycare or school after they have been receiving antibiotics for 24 hours, as they are considered noncontagious at that point.

TONSILLITIS

Inflammation of the tonsils often occurs with pharyngitis and thus may also be viral or bacterial in nature. Viral infections require only symptomatic treatment. Treatment for bacterial tonsillitis is the same as for bacterial pharyngitis. Occasionally surgical intervention is warranted. Tonsillectomy (surgical removal of the palatine tonsils) may be indicated for the child with recurrent streptococcal tonsillitis, massive tonsillar hypertrophy, or other reasons. When hypertrophied adenoids obstruct breathing, then adenoidectomy (surgical removal of the adenoids) may be indicated.

Nursing Assessment

Note whether fever is present currently or by history. Inquire about the history of recurrent pharyngitis or tonsillitis. Note if the child's voice sounds muffled or hoarse. Inspect the pharynx for redness and enlargement of the tonsils. As the tonsils enlarge, the child may experience difficulty breathing and swallowing. When tonsils touch at the midline ("kissing tonsils" or 4+ in size), the airway may become obstructed (see Fig. 39.7). Also, if the adenoids are enlarged, the posterior nares become obstructed. The child may breathe through the mouth and may snore. Palpate the anterior cervical nodes for enlargement and tenderness. Rapid test or culture may be positive for streptococcus A.

Nursing Management

Tonsillitis that is medically treated requires the same nursing management as pharyngitis. Nursing care for the child after tonsillectomy is described below.

Promoting Airway Clearance

Until fully awake, place the child in a side-lying or prone position to facilitate safe drainage of secretions. Once alert, he or she may prefer to sit up or have the head of the bed elevated. Suctioning, if necessary, should be done carefully to avoid trauma to the surgical site. Dried blood may be present on the teeth and the nares, with old blood present in emesis. Since the presence of blood can be very frightening to parents, alert them to this possibility.

Maintaining Fluid Volume

Hemorrhage is unusual postoperatively but may occur any time from the immediate postoperative period to as late as 10 days after surgery (Peterson & Losek, 2004). Inspect the throat for bleeding. Mucus tinged with blood may be expected, but fresh blood in the secretions indicates bleeding. Early bleeding may be identified by continuous swallowing of small amounts of blood while awake or sleeping. Other signs of hemorrhage include tachycardia, pallor, restlessness, frequent throat clearing, and emesis of bright red blood.

To avoid trauma to the surgical site, discourage the child from coughing, clearing the throat, blowing the nose, and using straws. Upon discharge, instruct the parents to immediately report any sign of bleeding to the physician. To maintain fluid volume postoperatively, encourage children to take any fluids they desire; Popsicles and ice chips are particularly soothing. Citrus juice and brown or red fluids should be avoided: the acid in citrus juice may irritate the throat, and red or brown fluids may be confused with blood if vomiting occurs.

Relieving Pain

For the first 24 hours after surgery, the throat is very sore. Adequate pain relief is essential to establish adequate oral fluid intake. An ice collar may be prescribed, as well as analgesics with or without narcotics. Counsel parents to maintain pain control upon discharge from the facility, not only for the child's sake but also to enable the child to continue to drink fluids (Louloudes, 2006).

INFECTIOUS MONONUCLEOSIS

Infectious mononucleosis is a self-limited illness caused by the Epstein-Barr virus. It is characterized by fever, malaise, sore throat, and lymphadenopathy. Mononucleosis is commonly called the "kissing disease" since it is transmitted by oropharyngeal secretions. It can occur at any age but is most often diagnosed in adolescents and young adults. Some infected individuals may have concomitant streptococcal pharyngitis. Complications include splenic rupture, Guillain-Barré syndrome, and aseptic meningitis (Jensen, 2004).

Nursing Assessment

Note any history of exposure to infected individuals. Determine history of fever and onset and progression of sore throat, malaise, and other complaints. Observe for periorbital edema. Inspect the pharynx and tonsils for inflammation and patches of gray exudate. Petechiae may be present on the palate. Palpate for bilateral nontender enlargement of the posterior cervical lymph nodes. After 3 to 5 days of illness, the pharynx may become edematous and the tonsillar exudate more extensive. Lymphadenopathy may progress to include the anterior cervical nodes, which may become tender. Palpate the abdomen for splenomegaly or hepatomegaly. An erythematous maculopapular rash may appear as the illness progresses. Definitive diagnosis may be made by Monospot or Epstein-Barr virus titers.

▶ *Take* NOTE!

The Monospot is usually negative if obtained within the first 7 to 10 days of illness with infectious mononucleosis. Epstein-Barr virus titer is reliable at any point in the illness.

Nursing Management

Nursing management of mononucleosis is primarily symptomatic. The throat may be very sore, so analgesics and salt-water gargles are recommended. Bed rest should be encouraged while the child is febrile. Frequent rest periods may be necessary for several weeks after the onset of illness, as fatigue may persist as long as 6 weeks. During the acute phase, if tonsillar or pharyngeal edema threatens to obstruct the airway, then corticosteroids may be given to decrease the inflammation. In the presence of splenomegaly or hepatomegaly, strenuous activity and contact sports should be avoided. Appearance of rash or jaundice should be reported to the physician.

▶ *Take* NOTE!

Concomitant strep throat in the presence of infectious mononucleosis should be treated with an antibiotic other than ampicillin, as it may cause an allergic-type rash if used in the presence of mononucleosis.

LARYNGITIS

Inflammation of the larynx is termed **laryngitis**. It may occur alone or in conjunction with other respiratory symptoms. It is characterized by a hoarse voice or loss of the voice (so soft as to make it difficult to hear). Oral fluids might offer relief, but resting the voice for 24 hours will allow the inflammation to subside. Laryngitis alone requires no further intervention.

CROUP

Children between 3 months and 3 years of age are the most frequently affected with croup, though croup may affect any child. Croup is also referred to as laryngotracheobronchitis because inflammation and edema of the larynx, trachea, and bronchi occur as a result of viral infection. Parainfluenza is responsible for the majority of cases of croup. Other causes include adenovirus, influenza virus A and B, RSV, and rarely measles virus or *Mycoplasma pneumoniae* (Bjornson et al., 2004). The inflammation and edema obstruct the airway, resulting in symptoms. Mucus production also occurs, further contributing to obstruction of the airway. Narrowing of the subglottic area of the trachea results in audible inspiratory stridor. Edema of the larynx causes hoarseness. Inflammation in the larynx and trachea causes the characteristic barking cough of croup. Symptoms occur most often at night, and croup is usually self-limited, lasting only about 3 to 5 days (Leung et al., 2004).

Croup often presents suddenly at night, with resolution of symptoms in the morning. Complications of croup are rare but may include worsening respiratory distress, hypoxia, or bacterial superinfection (as in the case of bacterial tracheitis). Croup is usually managed on an outpatient basis, with only 1% to 2% of cases requiring hospitalization (Leung et al., 2004).

Corticosteroids (usually a single dose) are used to decrease inflammation, and racemic epinephrine aerosols demonstrate the alpha-adrenergic effect of mucosal

vasoconstriction, helping to decrease edema (Bjornson et al., 2004; Schooff, 2005). Children with croup may be hospitalized if they have significant stridor at rest or severe retractions after a several-hour period of observation. Comparison Chart 39.2 compares croup to epiglottitis.

Nursing Assessment

Note the age of the child; children between 3 months and 3 years of age are most likely to present with viral croup (laryngotracheobronchitis). History may reveal a cough that developed during the night (most common presentation) and that sounds like barking (or a seal). Inspect for the presence of mild URI symptoms. Temperature may be normal or elevated mildly. Listen for inspiratory stridor and observe for suprasternal retractions. Auscultate the lungs for adequacy of breath sounds. Various scales are available for scoring croup severity, though these are of limited value in the clinical assessment and treatment of croup (Leung et al., 2004). Croup is usually diagnosed based on history and clinical presentation, but a lateral neck x-ray may be obtained to rule out epiglottitis.

▶ *Take* NOTE!

The child with fever, a toxic appearance, and increasing respiratory distress despite appropriate croup treatment may have bacterial tracheitis (Orenstein, 2004a). Notify the physician of these findings in a child with croup.

COMPARISON CHART 39.2 **CROUP VS. EPIGLOTTITIS**

	Spasmodic Croup	Epiglottitis
Preceding illness	None or minimal coryza	None or mild upper respiratory infection
Age group usually affected	3 months to 3 years	1 to 8 years
Onset	Usually sudden, often at night	Rapid (within hours)
Fever	Variable	High
Barking cough, hoarseness	Yes	No
Dysphagia	No	Yes
Toxic appearance	No	Yes
Cause	Viral	*Haemophilus influenzae* type B

TEACHING GUIDELINES 39.2

Home Care of Croup

- Keep the child quiet and discourage crying.
- Allow the child to sit up (in your arms).
- Encourage rest and fluid intake.
- If stridor occurs, take the child into a steamy bathroom for 10 minutes.
- Administer medication (corticosteroid) as directed.
- Watch the child closely. Call the physician if:
  - The child breathes faster, has retractions, or has any other difficulty breathing
  - The nostrils flare or the lips or nails have a bluish tint
  - The cough or stridor does not improve with exposure to moist air
  - Restlessness increases or the child is confused
  - The child begins to drool or cannot swallow

Adapted from Knutson & Aring, 2004.

Nursing Management

If the child's care is being managed at home, advise parents about the symptoms of respiratory distress and instruct them to seek treatment if the child's respiratory condition worsens. Teach parents to expose their child to humidified air (via a cool mist humidifier or steamy bathroom). Though never clinically proven, use of humidified air has long been recommended for alleviating coughing jags and anecdotally has been reported as helpful. Administer dexamethasone if ordered or teach parents about home administration. Explain to parents that the effects of racemic epinephrine last about 2 hours and the child must be observed closely as occasionally a child will worsen again, requiring another aerosol. Teaching Guidelines 39.2 provides information about home care of croup.

EPIGLOTTITIS

Epiglottitis (inflammation and swelling of the epiglottis) is most often caused by *Haemophilus influenzae* type b. Extensive use of the Hib vaccine since the 1980s has resulted in a significant decrease in the incidence of epiglottitis. Epiglottitis usually occurs in children between the ages of 2 and 7 years and can be life-threatening (Leung et al., 2004). Respiratory arrest and death may occur if the airway becomes completely occluded. Additional complications include pneumothorax and pulmonary edema. Therapeutic management focuses on airway maintenance and support. Intravenous antibiotic therapy is necessary.

The child will be managed in the intensive care unit. Comparison Chart 39.2 gives information comparing croup to epiglottitis.

Nursing Assessment

Carefully assess the child with suspected epiglottitis. Note sudden onset of symptoms and high fever. The child has an overall toxic appearance. He or she may refuse to speak or may speak only with a very soft voice. The child may refuse to lie down and may assume the characteristic position, sitting forward with the neck extended. Drooling may be present. Note anxiety or a frightened appearance. Note the child's color. Cough is usually absent. A lateral neck x-ray may be performed to determine whether epiglottitis is present. This is done cautiously, so as not to induce airway obstruction with changes in position of the child's neck (Bjornson et al., 2004).

Nursing Management

Do not leave the child unattended. Keep the child and parents as calm as possible. Allow the child to assume a position of comfort. Do not place the child in a supine position, as airway occlusion may occur. Provide 100% oxygen in the least invasive manner that is acceptable to the child. Do not under any circumstance attempt to visualize the throat: reflex laryngospasm may occur, precipitating immediate airway occlusion. If the child with epiglottitis experiences complete airway occlusion, an emergency tracheostomy may be necessary. Ensure that emergency equipment is available and that personnel trained in intubation of the pediatric occluded airway and percutaneous tracheostomy are notified of the child's presence in the facility (Bjornson et al., 2004).

▶ *Take* NOTE!

Epiglottitis is characterized by dysphagia, drooling, anxiety, irritability, and significant respiratory distress. Prepare for the event of sudden airway occlusion.

BRONCHIOLITIS (RSV)

Bronchiolitis is an acute inflammatory process of the bronchioles and small bronchi. Nearly always caused by a viral pathogen, RSV accounts for the majority of cases of bronchiolitis, with adenovirus, parainfluenza, and human meta-pneumovirus also being important causative agents. This discussion will focus on RSV bronchiolitis.

The peak incidence of bronchiolitis is in the winter and spring, coinciding with RSV season. RSV season in the United States and Canada generally begins in September or October and continues through April or May. Virtually all children will contract RSV infection within the first few years of life. RSV bronchiolitis occurs most often in infants and toddlers, with a peak incidence around 6 months of age. The severity of disease is related inversely to the age of the child. The frequency and severity of RSV infection decrease with age. Repeated RSV infections occur throughout life but are usually localized to the upper respiratory tract after toddlerhood.

Therapeutic Management

Management of RSV focuses on supportive treatment. Supplemental oxygen, nasal and/or nasopharyngeal suctioning, oral or intravenous hydration, and inhaled bronchodilator therapy are used. Many infants are managed at home with close observation and adequate hydration. Hospitalization is required for children with more severe disease. The infant with tachypnea, significant retractions, poor oral intake, or lethargy can deteriorate quickly, to the point of requiring ventilatory support, and thus warrants hospital admission.

Pathophysiology

RSV is a highly contagious virus and may be contracted through direct contact with respiratory secretions or from particles on objects contaminated with the virus (Lauts, 2005). RSV invades the nasopharynx, where it replicates and then spreads down to the lower airway via aspiration of upper airway secretions. RSV infection causes necrosis of the respiratory epithelium of the small airways, peribronchiolar mononuclear infiltration, and plugging of the lumens with mucus and exudate. The small airways become variably obstructed; this allows adequate inspiratory volume but prevents full expiration. This leads to hyperinflation and atelectasis (Bennett, 2006). Serious alterations in gas exchange occur, with arterial hypoxemia and carbon dioxide retention resulting from mismatching of pulmonary ventilation and perfusion. Hypoventilation occurs secondary to markedly increased work of breathing.

Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1222. Assessment findings pertinent to bronchiolitis are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Onset of illness with a clear runny nose (sometimes profuse)
- Pharyngitis

- Low-grade fever
- Development of cough 1 to 3 days into the illness, followed by a wheeze shortly thereafter
- Poor feeding

Explore the child's current and past medical history for risk factors such as:

- Young age (less than 2 years old), more severe disease in a child less than 6 months old
- Prematurity
- Multiple births
- Birth during April to September
- History of chronic lung disease (bronchopulmonary disease)
- Cyanotic or complicated congenital heart disease
- Immunocompromise
- Male gender
- Exposure to passive tobacco smoke
- Crowded living conditions
- Daycare attendance
- School-age siblings
- Low socioeconomic status
- Lack of breastfeeding

Physical Examination

Examination of the child with RSV involves inspection, observation, and auscultation.

Inspection and Observation

Observe the child's general appearance and color (centrally and peripherally). The infant with RSV bronchiolitis might appear air-hungry, exhibiting various degrees of cyanosis and respiratory distress, including tachypnea, retractions, accessory muscle use, grunting, and periods of apnea. Cough and audible wheeze might be heard. The infant might appear listless and uninterested in feeding, surroundings, or parents.

Auscultation

Auscultate the lungs, noting adventitious sounds and determining the quality of aeration of the lung fields. Earlier in the illness, wheezes might be heard scattered throughout the lung fields. In more serious cases, the chest might sound quiet and without wheeze. This is due to significant hyperexpansion with very poor air exchange.

Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of RSV bronchiolitis include:

- Pulse oximetry: oxygen saturation might be significantly decreased
- Chest x-ray: might reveal hyperinflation and patchy areas of atelectasis or infiltration
- Blood gases: might show carbon dioxide retention and hypoxemia
- Nasal-pharyngeal washings: positive identification of RSV can be made via enzyme-linked immunosorbent assay (ELISA) or immunofluorescent antibody (IFA) testing

Nursing Management

RSV infection is usually self-limited, and nursing diagnoses, goals, and interventions for the child with bronchiolitis are aimed at supportive care. Children with less severe disease might require only antipyretics, adequate hydration, and close observation. They can often be successfully managed at home, provided the primary caregiver is reliable and comfortable with close observation. Parents or caregivers should be educated to watch for signs of worsening and must understand the importance of seeking care quickly should the child's condition deteriorate.

Hospitalization is required for children with more severe disease, and children admitted with RSV bronchiolitis warrant close observation. In addition to the nursing diagnoses and related interventions discussed in the Nursing Care Plan for respiratory disorders, interventions common to bronchiolitis follow.

▶ *Take* NOTE!

Currently no safe and effective antiviral drug is available for definitive treatment of RSV. Aerosolized ribavirin is recommended only for the highest-risk, most severely ill patients (Lauts, 2005). Routine antibiotic use is discouraged in RSV bronchiolitis treatment because the secondary bacterial infection rate of the lower airway is very low.

Maintaining Patent Airway

Infants and young children with RSV tend to have copious secretions. Position the child with the head of the bed elevated to facilitate an open airway. These children often require frequent assessment and suctioning to maintain a patent airway (Lauts, 2005). Use a Yankauer or tonsil-tip suction catheter to suction the mouth or pharynx of older infants or children, rinsing the catheter after each suctioning. Nasal bulb suctioning may be sufficient to clear the airway in some infants, while others will require nasopharyngeal suctioning with a suction catheter. Nursing Procedure 39.1 gives further information. Adjust the pressure ranges for suctioning infants and children between 60 and 100 mm Hg, 40 and 60 mm Hg for premature infants.

Nursing Procedure 39.1

NASOPHARYNGEAL OR ARTIFICIAL AIRWAY SUCTION TECHNIQUE

1. Make sure the suction equipment works properly before starting.
2. After washing your hands, assemble the equipment needed:
   - Appropriate-size sterile suction catheter
   - Sterile gloves
   - Supplemental oxygen
   - Sterile water-based lubricant
   - Sterile normal saline if indicated
3. Don sterile gloves, keeping dominant hand sterile and nondominant hand clean.
4. Preoxygenate the infant or child if indicated.
5. Apply lubricant to the end of the suction catheter.
6. If indicated for loosening of secretions, instill sterile saline.
7. Maintaining sterile technique, insert the suction catheter into the child's nostril or airway.
   - Insert only to the point of gagging if inserting via the nostril.
   - Insert only 0.5 cm further than the length of the artificial airway.
8. Intermittently apply suction for no longer than 10 seconds, while twisting and removing the catheter.
9. Supplement with oxygen after suctioning.

Promoting Adequate Gas Exchange

Infants and children with bronchiolitis might deteriorate quickly as the disease progresses. In the child ill enough to require oxygen, the risk is even greater. Assessment should include work of breathing, respiratory rate, and oxygen saturation. The percentage of inspired oxygen (FiO_2) should be adjusted as needed to maintain oxygen saturation within the desired range. Positioning the infant with the head of the bed elevated may also improve gas exchange. Frequent assessment is necessary for the hospitalized child with bronchiolitis (Steiner, 2004).

▶ *Take* NOTE!

In the tachypneic infant, slowing of the respiratory rate does not necessarily indicate improvement: often, a slower respiratory rate is an indication of tiring, and carbon dioxide retention may soon be followed by apnea.

Reducing Risk for Infection

Since RSV is easily spread through contact with droplets, inpatients should be isolated according to hospital policy to decrease the risk of nosocomial spread to other clients. Clients with RSV can be safely cohorted. Attention to handwashing is necessary, as droplets might enter the eyes, nose, or mouth via the hands.

Providing Family Education

Educate parents so they can recognize signs of worsening distress. Tell parents to call the physician or nurse practitioner if the child's breathing becomes rapid or more difficult or if the child cannot eat secondary to tachypnea. Children who are less than 1 year of age or who are at higher risk (those who were born prematurely or who have chronic heart or lung conditions) might have a longer course of illness. Instruct parents that cough can persist for several days to weeks after resolution of the disease, but infants usually act well otherwise.

Preventing RSV Disease

Strict adherence to handwashing policies in daycare centers and when exposed to individuals with cold symptoms is important for all groups. Though generally benign in healthy older children, RSV can be devastating in young infants or children with pre-existing risk factors. Palivizumab (Synagis) is a monoclonal antibody that can prevent severe RSV disease in those who are most susceptible. It is given as an intramuscular injection once a month throughout the RSV season. Though quite costly, it is covered by most insurance policies and Medicaid for those who qualify. It is generally indicated for use in certain children less than 2 years of age. Qualifying factors include:

- Prematurity
- Chronic lung disease (bronchopulmonary dysplasia) requiring medication or oxygen
- Certain congenital heart diseases
- Immunocompromise (Bennett, 2006)

Additional information related to Synagis may be found at http://www.synagis.com/.

PNEUMONIA

Pneumonia is an inflammation of the lung parenchyma. It can be caused by a virus, bacteria, *Mycoplasma*, or fungus. It may also result from aspiration of foreign material into the lower respiratory tract (aspiration pneumonia). Pneumonia occurs more often in winter and early spring. It is common in children but is seen most frequently in infants and young toddlers. Viruses are the most common cause of pneumonia in younger children and the least

common cause in older children (Table 39.2). Viral pneumonia is usually better tolerated in children of all ages. Children with bacterial pneumonia are more apt to present with a toxic appearance, but they generally recover rapidly if appropriate antibiotic treatment is instituted early.

▶ *Take* NOTE!

Community-acquired pneumonia (CAP) refers to pneumonia in a previously healthy person that is contracted outside of the hospital setting. CAP is a common cause of lower respiratory infection in North America (Ostapchuk et al., 2004).

Pneumonia is usually a self-limited disease. A child who presents with recurrent pneumonia should be evaluated for chronic lung disease such as asthma or cystic fibrosis. Potential complications of pneumonia include bacteremia, pleural effusion, empyema, lung abscess, and pneumothorax (Nield et al., 2005). Excluding bacteremia, these are often treated with thoracentesis and/or chest tubes as well as antibiotics if appropriate. Pneumatoceles (thin-walled cavities developing in the lung) might occur with certain bacterial pneumonias and usually resolve spontaneously over time.

Therapeutic management of children with less severe disease includes antipyretics, adequate hydration, and close observation. Even bacterial pneumonia can be successfully managed at home if the work of breathing is not severe and oxygen saturation is within normal limits. However, hospitalization is required for children with more severe disease. The child with tachypnea, significant retractions, poor oral intake, or lethargy might require hospital admission for the administration of supplemental oxygen, intravenous hydration, and antibiotics.

TABLE 39.2 Common Causes of Pneumonia According to Age

Age Group	Most Common Causative Agents
1 to 3 months	RSV, other respiratory viruses (parainfluenza, influenza, adenovirus); *Streptococcus pneumoniae, Chlamydia trachomatis*
4 months to 5 years	Respiratory viruses, *Streptococcus pneumoniae, Chlamydia pneumoniae, Mycoplasma pneumoniae*
5 to 18 years	*Mycoplasma pneumoniae, Chlamydia pneumoniae, Streptococcus pneumoniae*

Sources: Nield et al., 2005; Ostapchuk, 2004.

▶ *Take* NOTE!

Haemophilus influenzae type B has been nearly eliminated as a cause of pneumonia in the United States and other developed countries as a result of universal immunization with Hib vaccine.

Pathophysiology

Pneumonia occurs as a result of the spread of infectious organisms to the lower respiratory tract from either the upper respiratory tract or the bloodstream. In bacterial pneumonia, mucus stasis occurs as a result of vascular engorgement. Cellular debris (erythrocytes, neutrophils, and fibrin) accumulates in the alveolar space. Relative hyperexpansion with air trapping follows. Inflammation of the alveoli results in **atelectasis** (a collapsed or airless portion of the lung), so gas exchange becomes impaired. The inflammatory response further impairs gas exchange (Nield et al., 2005).

Viral pneumonia usually results in an inflammatory reaction limited to the alveolar wall. Aspiration of food, fluids, or other substances into the bronchial tree can result in aspiration pneumonia. Aspiration is the most common cause of recurrent pneumonia in children and often occurs as a result of gastroesophageal reflux disease. Secondary bacterial infection often occurs following viral or aspiration pneumonia and requires antibiotic treatment.

Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1222. Assessment findings pertinent to pneumonia are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Note onset and progression of symptoms. Common signs and symptoms reported during the health history include:

- Antecedent viral URI
- Fever
- Cough (note type and whether productive or not)
- Increased respiratory rate
- History of lethargy, poor feeding, vomiting, or diarrhea in infants
- Chills, headache, dyspnea, chest pain, abdominal pain, and nausea or vomiting in older children

Explore the child's past and current medical history for risk factors known to be associated with an increase in the severity of pneumonia, such as:

- Prematurity
- Malnutrition

- Passive smoke exposure
- Low socioeconomic status
- Daycare attendance
- Underlying cardiopulmonary, immune, or nervous system disease

Physical Examination

Physical examination consists of inspection, auscultation, percussion, and palpation.

Inspection

Observe the child's general appearance and color (centrally and peripherally). Cyanosis might accompany coughing spells. The child with bacterial pneumonia may appear ill. Assess work of breathing. Children with pneumonia might exhibit substernal, subcostal, or intercostal retractions. Tachypnea and nasal flaring may be present. Describe cough and quality of sputum if produced.

Auscultation

Auscultation of the lungs might reveal wheezes or rales in the younger child. Local or diffuse rales may be present in the older child. Document diminished breath sounds.

Percussion and Palpation

In the older child, percussion might yield local dullness over a consolidated area. Percussion is much less valuable in the infant or younger child. Tactile fremitus felt upon palpation may be increased with pneumonia.

Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of pneumonia include:

- Pulse oximetry: oxygen saturation might be significantly decreased or within normal range
- Chest x-ray: varies according to client age and causative agent. In infants and young children, bilateral air trapping and perihilar **infiltrates** are the most common findings. Patchy areas of consolidation might also be present. In older children, lobar consolidation is seen more frequently.
- Sputum culture: may be useful in determining causative bacteria in older children and adolescents
- White blood cell count: might be elevated in the case of bacterial pneumonia

Nursing Management

Nursing diagnoses, goals, and interventions for the child with pneumonia are primarily aimed at providing supportive care and education about the illness and its treatment. Prevention of pneumococcal infection is also important. Children with more severe disease will require hospitalization. Refer to Nursing Care Plan 39.1 for nursing diagnoses and related interventions. In addition to the interventions listed there, the following should be noted.

Providing Supportive Care

Ensure adequate hydration and assist in thinning of secretions by encouraging oral fluid intake in the child whose respiratory status is stable. In children with increased work of breathing, intravenous fluids may be necessary to maintain hydration. Allow and encourage the child to assume a position of comfort, usually with the head of the bed elevated to promote aeration of the lungs. If pain due to coughing or pneumonia itself is severe, administer analgesics as prescribed. Provide supplemental oxygen to the child with respiratory distress or hypoxia as needed.

Providing Family Education

Educate the family about the importance of adhering to the prescribed antibiotic regimen. Antibiotics may be given intravenously if the child is hospitalized, but upon discharge or if the child is managed on an outpatient basis, oral antibiotics will be used.

Teach the parents of a child with bacterial pneumonia to expect that following resolution of the acute illness, for 1 to 2 weeks the child might continue to tire easily and the infant might continue to need small, frequent feedings. Cough may also persist after the acute recovery period but should lessen over time.

If the child is diagnosed with viral pneumonia, parents might not understand that their child does not require an antibiotic. Pneumonia is often perceived by the public as a bacterial infection, so most parents will need an explanation related to treatment of viral infections. As with bacterial pneumonia, the child may experience a week or two of weakness or fatigue following resolution of the acute illness.

The young child is at risk for the development of aspiration pneumonia. Parents need to understand that the child might be at risk for injury related to his or her age and developmental stage. To prevent recurrent or further aspiration, teach the parents the safety measures in Teaching Guidelines 39.3.

Preventing Pneumococcal Infection

Children at high risk for severe pneumococcal infection should be immunized against it. This includes all children between 0 and 23 months of age, as well as children between 24 and 59 months of age who either never received the vaccine before age 2 or did not receive a booster dose between 12 and 23 months of age. Additionally, children between 24 and 59 months of age with certain conditions such as immune deficiency, sickle cell disease, asplenia, chronic cardiac conditions, chronic lung problems, cerebrospinal fluid leaks, chronic renal insufficiency, diabetes mellitus, and organ transplants, should receive the vaccine. For additional information on immunization, refer to Chapter 30.

TEACHING GUIDELINES 39.3

Preventing Aspiration

- Keep toxic substances such as lighter fluid, solvents, and hydrocarbons out of reach of young children. Toddlers and preschoolers cannot distinguish safe from unsafe fluids due to their developmental stage.
- Avoid oily nose drops and oil-based vitamins or home remedies to avoid lipid aspiration into the lungs.
- Avoid oral feedings if the infant's respiratory rate is 60 or greater to minimize the risk of aspiration of the feeding.
- Discourage parents from "force-feeding" in the event of poor oral intake or severe illness to minimize the risk of aspiration of the feeding.
- Position infants and ill children on their right side after feeding to minimize the risk of aspirating emesis or regurgitated feeding.

BRONCHITIS

Bronchitis is an inflammation of the trachea and major bronchi. It is often associated with a URI. Bronchitis is usually viral in nature, though *Mycoplasma pneumoniae* is also an important causative agent in children over 6 years of age. Recovery usually occurs within 5 to 10 days. Therapeutic management involves mainly supportive care. Expectorant administration and adequate hydration are important. If *Mycoplasma* is the cause, antibiotics are indicated (Orenstein, 2004b).

Nursing Assessment

The illness might begin with a mild URI. Fever develops, followed by a dry, hacking cough that might become productive in older children. The cough might wake the child at night. Auscultation of the lungs might reveal coarse rales. Respirations remain unlabored. The chest x-ray might show diffuse alveolar hyperinflation and perihilar markings.

HEALTHY PEOPLE 2010

Objective	Significance
Reduce invasive pneumococcal infections.	• Provide accurate information to families about pneumococcal disease. • Encourage pneumococcal immunization per recommendations.

Nursing Management

Nursing management is aimed at providing supportive care. Teach parents that expectorants will help loosen secretions and antipyretics will help reduce the fever, making the child more comfortable. Encourage adequate hydration. Antibiotics are prescribed only in cases believed to be bacterial in nature. Discourage the use of cough suppressants: it is important for accumulated sputum to be raised.

TUBERCULOSIS

Tuberculosis is a highly contagious disease caused by inhalation of droplets of *Mycobacterium tuberculosis* or *Mycobacterium bovis*. Children usually contract the disease from an immediate household member. Annually about 1,000 U.S. children contract active tuberculosis disease (Reznik & Ozuah, 2005). Nonwhite children and children with chronic illness or malnutrition are more susceptible to infection. After exposure to an infected individual, the incubation period is 2 to 10 weeks. The inhaled tubercle bacilli multiply in the alveoli and alveolar ducts, forming an inflammatory exudate. The bacilli are spread by the bloodstream and lymphatic system to various parts of the body. Though pulmonary tuberculosis is the most common, children may also have infection in other parts of the body, such as the gastrointestinal tract or central nervous system.

In the case of drug-sensitive tuberculosis, the American Academy of Pediatrics recommends a 6-month course of oral therapy. The first 2 months consist of isoniazid,

HEALTHY PEOPLE 2010

Objective	Significance
Reduce tuberculosis. Increase the proportion of all tuberculosis patients who complete curative therapy within 12 months. Increase the proportion of contacts and other high-risk persons with latent tuberculosis infection who complete a course of treatment.	• Assess the health history of all infants, children, and adolescents for risk factors for tuberculosis infection. • Provide tuberculosis screening as recommended. • Refer all tuberculosis infections to the local public health department. • Educate families about the importance of completing medication therapy as prescribed for active and latent tuberculosis, and the need for appropriate follow-up and retesting for tuberculosis infection.

rifampin, and pyrazinamide given daily. This is followed by twice-weekly isoniazid and rifampin; administration must be observed directly (usually by a public health nurse). In the case of multidrug-resistant tuberculosis, ethambutol or streptomycin is given via intramuscular injection (Pickering, 2006).

Nursing Assessment

Routine screening for tuberculosis infection is not recommended for low-risk individuals, but children considered to be at high risk for contracting tuberculosis should be screened using the Mantoux test. Children considered to be at high risk are those who:

- Are infected with HIV
- Are incarcerated or institutionalized
- Have a positive recent history of latent tuberculosis infection
- Are immigrants from or have a history of travel to endemic countries
- Are exposed at home to HIV-infected or homeless persons, illicit drug users, persons recently incarcerated, migrant farm workers, or nursing home residents

Children with chronic illnesses (except HIV infection) are not more likely to become infected with tuberculosis but should receive special consideration and be screened prior to initiation of immunosuppressant therapies (Reznik & Ozuah, 2005).

The presentation of tuberculosis in children is quite varied. Children can be asymptomatic or exhibit a broad range of symptoms. Symptoms may include fever, malaise, weight loss, anorexia, pain and tightness in the chest, and rarely hemoptysis. Cough might or might not be present and usually progresses slowly over several weeks to months. As tuberculosis progresses, the respiratory rate increases and the lung on the affected side is poorly expanded. Dullness to percussion might be present, as well as diminished breath sounds and crackles. Fever persists and pallor, anemia, weakness, and weight loss are present. Diagnosis is confirmed with a positive Mantoux test, positive gastric washings for acid-fast bacillus, and/or a chest x-ray consistent with tuberculosis (Reznik & Ozuah, 2005).

Nursing Management

Hospitalization of children with tuberculosis is necessary only for the most serious cases. Nursing management is aimed at providing supportive care and encouraging adherence to the treatment regimen. Most nursing care for childhood tuberculosis is provided in outpatient clinics, schools, or a public health setting. Supportive care includes ensuring adequate nutrition and adequate rest, providing comfort measures such as fever reduction, preventing exposure to other infectious diseases, and preventing reinfection.

Providing Care for the Child With Latent Tuberculosis Infection

Children who test positive for tuberculosis but who do not have symptoms or radiographic/laboratory evidence of disease are considered to have latent infection. These children should be treated with isoniazid for 9 months to prevent progression to active disease. Follow-up and appropriate monitoring can be achieved via the child's primary care provider or local health department.

Preventing Infection

Tuberculosis infection is prevented by avoiding contact with the tubercle bacillus. Thus, hospitalized children with tuberculosis must be isolated according to hospital policy to prevent nosocomial spread of tuberculosis infection. Promotion of natural resistance through nutrition, rest, and avoidance of serious infections does not prevent infection. Pasteurization of milk has helped to decrease the transmission of *Mycobacterium bovis*. Administration of bacille Calmette-Guérin (BCG) vaccine can provide incomplete protection against tuberculosis, and it is not widely used in the United States.

Acute Noninfectious Disorders

Acute noninfectious disorders include epistaxis, foreign body aspiration, respiratory distress syndrome, acute respiratory distress syndrome, and pneumothorax.

EPISTAXIS

Epistaxis (a nosebleed) occurs most frequently in children before adolescence. Bleeding of the nasal mucosa occurs most often from the anterior portion of the septum. Epistaxis may be recurrent and idiopathic (meaning there is no cause). The majority of cases are benign, but in children with bleeding disorders or other hematologic concerns, epistaxis should be further investigated and treated.

Take NOTE!

The child with recurrent epistaxis or epistaxis that is difficult to control should be further evaluated for underlying bleeding or platelet concerns.

Nursing Assessment

Explore the child's history for initiating factors such as local inflammation, mucosal drying, or local trauma (usually nose picking). Inspect the nasal cavity for blood.

Nursing Management

The presence of blood often frightens children and their parents. The nurse and parents should remain calm. The child should sit up and lean forward (lying down may allow aspiration of the blood). Apply continuous pressure to the anterior portion of the nose by pinching it closed. Encourage the child to breathe through the mouth during this portion of the treatment. Ice or a cold cloth applied to the bridge of the nose may also be helpful. The bleeding usually stops within 10 to 15 minutes. Apply petroleum jelly or water-soluble gel to the nasal mucosa with a cotton-tipped applicator to moisten the mucosa and prevent recurrence.

FOREIGN BODY ASPIRATION

Foreign body aspiration occurs when any solid or liquid substance is inhaled into the respiratory tract. It is common in infants and young children and can present in a life-threatening manner. The object may lodge in the upper or lower airway, causing varying degrees of respiratory difficulty. Small, smooth objects such as peanuts are the most frequently aspirated, but any small toy, article, or piece of food smaller than the diameter of the young child's airway can be aspirated.

Foreign body aspiration occurs most frequently in children ages 6 months to 5 years. Children this age are growing and developing rapidly. They tend to explore things with their mouths and can easily aspirate small items.

The child often coughs out foreign bodies from the upper airway. If the foreign body reaches the bronchus, then it may need to be surgically removed via bronchoscopy. Postoperative antibiotics are used if an infection is also present. Complications of foreign body aspiration include pneumonia or abscess formation, hypoxia, respiratory failure, and death (Orenstein, 2004c).

Nursing Assessment

The infant or young child might present with a history of sudden onset of cough, wheeze, or stridor. Stridor suggests that the foreign body is lodged in the upper airway. Sometimes the onset of respiratory symptoms is much more gradual. When the item has traveled down one of the bronchi, then wheezing, rhonchi, and decreased aeration can be heard on the affected side. A chest x-ray will demonstrate the foreign body only if it is radiopaque (Fig. 39.8).

Nursing Management

The most important nursing intervention related to foreign body aspiration is prevention. Anticipatory guidance for families with 6-month-olds should include a discussion of aspiration avoidance. This information should be repeated at each subsequent well-child visit through age 5. Tell parents to avoid letting their child play with toys with small parts and to keep coins and other small objects out of the reach of children. Teach parents not to feed peanuts and popcorn to their child until he or she is at least 3 years old. When children progress to table food, teach parents to chop all foods so that they are small enough to pass down the trachea should the child neglect to chew them up thoroughly. Carrots, grapes, and hot dogs should be cut into small pieces. Harmful liquids should be kept out of the reach of children.

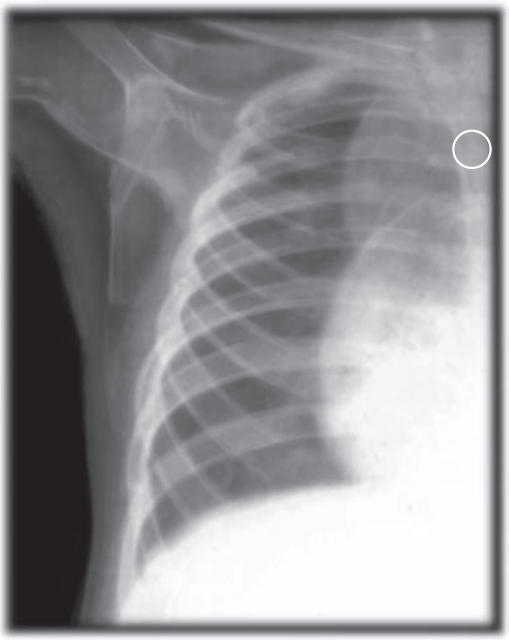


FIGURE 39.8 Foreign body is noted in the bronchus on a chest x-ray.

Take NOTE!

Items smaller than 1.25 inches (3.2 cm) can be aspirated easily. A simple way for parents to estimate the safe size of a small item or toy piece is to gauge its size against a standard toilet paper roll, which is generally about 1.5 inches in diameter.

RESPIRATORY DISTRESS SYNDROME

Respiratory distress syndrome (RDS) is a respiratory disorder that is specific to neonates. It results from lung immaturity and a deficiency in surfactant, so it is seen most

often in premature infants. Other infants who might experience RDS include infants of diabetic mothers, those delivered via cesarean section without preceding labor, and those experiencing perinatal asphyxia. It is believed that each of these conditions has an impact on surfactant production, thus resulting in RDS in the term infant (Stoll & Kliegman, 2004).

The administration of surfactant via an endotracheal tube shortly after delivery helps to decrease the incidence and severity of RDS. Management of RDS focuses on intensive respiratory care, usually with mechanical ventilation. Newer techniques for ventilatory support are also available (Table 39.3).

Pathophysiology

The lack of surfactant in the affected newborn's lungs results in stiff, poorly compliant lungs with poor gas exchange. Right-to-left shunting and hypoxemia result. As the disease progresses, fluid and fibrin leak from the pulmonary capillaries, causing a hyaline membrane to form in the bronchioles, alveolar ducts, and alveoli. Presence of the membrane further decreases gas exchange. Complications of RDS include air leak syndrome, bronchopulmonary dysplasia, patent ductus arteriosus and congestive heart failure, intraventricular hemorrhage, retinopathy of prematurity, necrotizing enterocolitis, complications resulting from intravenous catheter use (infection, thrombus formation), and developmental delay or disability (Stoll & Kliegman, 2004).

Nursing Assessment

The onset of RDS is usually within several hours of birth. The newborn exhibits signs of respiratory distress, including tachypnea, retractions, nasal flaring, grunting, and varying degrees of cyanosis. Auscultation reveals fine rales and diminished breath sounds. If untreated, RDS progresses to seesaw respirations, respiratory failure, and shock.

Nursing Management

Rarely, mucus plugging can occur in the neonate placed on a ventilator after surfactant administration. Therefore, close observation and assessment for adequate lung expansion are critical. In addition to expert respiratory intervention, other crucial nursing goals include maintenance of normothermia, prevention of infection, maintenance of fluid and electrolyte balance, and promotion of adequate nutrition (parenterally or via gavage feeding). Nursing care of the infant with RDS generally occurs in the intensive care unit.

ACUTE RESPIRATORY DISTRESS SYNDROME

Acute respiratory distress syndrome (ARDS) occurs following a primary insult such as sepsis, viral pneumonia, smoke inhalation, or near-drowning. Respiratory distress and hypoxemia occur acutely within 72 hours of the insult in infants and children with previously healthy lungs. The alveolar–capillary membrane becomes more permeable and pulmonary edema develops. Hyaline membrane formation over the alveolar surfaces and decreased surfactant production cause lung stiffness. Mucosal swelling and cellular debris lead to atelectasis. Gas diffusion is impaired significantly. ARDS can progress to respiratory failure and death, though some individuals recover completely or have residual lung disease.

Medical treatment is aimed at improving **oxygenation** and **ventilation**. Mechanical ventilation is used, with special attention to lung volumes and positive end-expiratory

TABLE 39.3 Alternatives to Traditional Mechanical Ventilation

Mode	Description	Additional Information
High-frequency ventilators (high-frequency, oscillating, or jet)	Provide very high respiratory rates (up to 1,200 breaths per minute) and very low tidal volumes	May decrease risk of barotrauma associated with ventilator pressures
Nitric oxide	Causes pulmonary vasodilation, helping to increase blood flow to alveoli	Safe; no long-term developmental risks
Liquid ventilation	Perfluorocarbon liquid acts as a surfactant. Provides an effective medium for gas exchange and increases pulmonary function.	Virtually no reported physiologic sequelae
Extracorporeal membrane oxygenation (ECMO)	Blood is removed from body via catheter, warmed and oxygenated in the ECMO machine, and then returned to infant.	Labor-intensive. Risk of bleeding is great.

pressure (PEEP). Newer treatment modalities show promise for improving outcomes of ARDS.

Nursing Assessment

Tachycardia and tachypnea occur over the first few hours of the illness. Significantly increased work of breathing with nasal flaring and retractions develops. Auscultate for breath sounds, which might range from normal to high-pitched crackles throughout the lung fields. Hypoxemia develops. Bilateral infiltrates can be seen on a chest x-ray.

Nursing Management

Nursing care of the child with ARDS is mainly supportive and occurs in the intensive care unit. Closely monitor respiratory and cardiovascular status. Comfort measures such as hygiene and positioning as well as pain and anxiety management, maintenance of nutrition, and prevention of infection are also key nursing interventions. The acute phase of worsening respiratory distress can be frightening for a child of any age, and the nurse can be instrumental in soothing the child's fears. As the disease worsens and progresses, especially when ventilatory support is required, psychological support of the family as well as education about the intensive care unit procedures will be especially important.

PNEUMOTHORAX

A collection of air in the pleural space is called a pneumothorax. It can occur spontaneously in an otherwise healthy child or as a result of chronic lung disease, cardiopulmonary resuscitation, surgery, or trauma. Trapped air consumes space within the pleural cavity, and the affected lung suffers at least partial collapse. Needle aspiration and/or placement of a chest tube is used to evacuate the air from the chest. Some small pneumothoraces resolve independently, without intervention (Kerby et al., 2007).

Nursing Assessment

Primary pneumothorax (spontaneous) occurs most often in adolescence. The infant or child with a pneumothorax might have a sudden or gradual onset of symptoms. Chest pain might be present as well as signs of respiratory distress such as tachypnea, retractions, nasal flaring, or grunting. Assess risk factors for acquiring a pneumothorax, including chest trauma or surgery, intubation and mechanical ventilation, or a history of chronic lung disease such as cystic fibrosis. Inspect the child for a pale or cyanotic appearance. Auscultate for increased heart rate (tachycardia) and absent or diminished breath sounds on the affected side. The x-ray reveals air within the thoracic cavity (Fig. 39.9).

Nursing Management

The child with a pneumothorax requires frequent respiratory assessments. Pulse oximetry might be used as an adjunct, but clinical evaluation of respiratory status is most useful. In some cases, administration of 100% oxygen hastens the reabsorption of air, but it is generally used only for a few hours. If a chest tube is connected to a dry suction or water seal apparatus, provide care of the drainage apparatus as appropriate (Fig. 39.10). A pair of hemostats should be kept at the bedside to clamp the tube should it become dislodged from the drainage container. The dressing around the chest tube is occlusive and is not routinely changed. If the tube becomes dislodged from the child's chest, apply Vaseline gauze and an occlusive dressing, immediately perform appropriate respiratory assessment, and notify the physician.

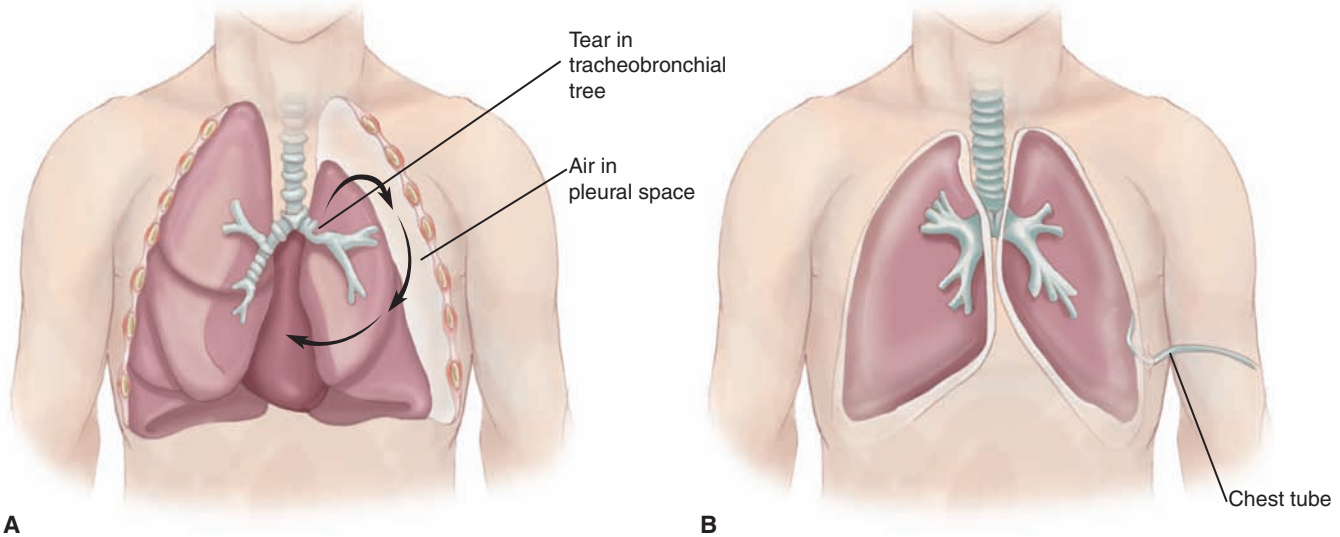

FIGURE 39.9 Pneumothorax.

FIGURE 39.10 The chest tube is connected to suction or water seal via a drainage container.

Chronic Diseases

Chronic respiratory disorders include allergic rhinitis, asthma, chronic lung disease (bronchopulmonary dysplasia), cystic fibrosis, and apnea.

ALLERGIC RHINITIS

Allergic **rhinitis** is a common chronic condition in childhood, affecting up to 40% of children (Hagemann, 2005). Allergic rhinitis is associated with atopic dermatitis and asthma, with as many as 60% to 78% of asthmatic children also suffering from allergic rhinitis (Rance, 2007). Perennial allergic rhinitis occurs year-round and is associated with indoor environments. Allergens commonly implicated in perennial allergic rhinitis include dust mites, pet dander, cockroach antigens, and molds. Seasonal allergic rhinitis is caused by elevations in outdoor levels of allergens. It is typically caused by certain pollens, trees, weeds, fungi, and molds. Complications from allergic rhinitis include exacerbation of asthma symptoms, recurrent sinusitis and otitis media, and dental malocclusion.

Pathophysiology

Allergic rhinitis is an intermittent or persistent inflammatory state that is mediated by immunoglobulin E (IgE). In response to contact with an airborne allergen protein, the nasal mucosa mounts an immune response. The antigen (from the allergen) binds to a specific IgE on the surface of mast cells, releasing the chemical mediators of histamine and leukotrienes. The release of mediators results in acute tissue edema and mucus production (Banasiak & Meadows-Oliver, 2005). Late-phase mediators are released and more inflammation results. IgE binds to receptors on the surfaces of mast cells and basophils, creating the sensitization memory that causes the reaction with subsequent allergen exposures. Allergen exposure then results in mast cell degranulation and release of histamine and other chemotactic factors. Histamine and other factors cause nasal vasodilation, watery **rhinorrhea**, and nasal congestion. Irritation of local nerve endings by histamine produces pruritus and sneezing (Hagemann, 2005). Treatment of allergic rhinitis is aimed at decreasing response to these allergic mediators as well as treating inflammation.

Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1222. Assessment findings pertinent to allergic rhinitis are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Mild, intermittent to chronic nasal stuffiness
- Thin, runny nasal discharge
- Sneezing
- Itching of nose, eyes, palate
- Mouth breathing and snoring

Determine the seasonality of symptoms. Are they perennial (year-round) or do they occur during certain seasons only? What types of medications or other treatments have been used, and what was the child's response?

Explore the history for the presence of risk factors such as:

- Family history of atopic disease (asthma, allergic rhinitis, or atopic dermatitis)
- Known allergy to dust mites, pet dander, cockroach antigens, pollens, or molds
- Early childhood exposure to indoor allergens
- Early introduction to foods or formula in infancy
- Exposure to tobacco smoke
- Environmental air pollution
- Recurrent viral infections

Nonwhite race and higher socioeconomic status have also been noted as risk factors (Hagemann, 2005).

Physical Examination

Physical examination of the child with allergic rhinitis includes inspection, observation, and auscultation.

Inspection and Observation

Observe the child's facies for red-rimmed eyes or tearing, mild eyelid edema, "allergic shiners" (bluish or grayish cast beneath the eyes), and "allergic salute" (a transverse nasal crease between the lower and middle thirds of the nose that results from repeated nose rubbing) (Fig. 39.11).

FIGURE 39.11 Allergic shiners beneath the eyes and allergic salute across the nose.

Inspect the nasal cavity. The turbinates may be swollen and gray/blue. Clear mucoid nasal drainage may be observed. Inspect the skin for rash. Listen for nasal phonation with speech.

Auscultation

Auscultate the lungs for adequate aeration and clarity of breath sounds. In the child who also has asthma, exacerbation with wheezing often occurs with allergic rhinitis.

Laboratory and Diagnostic Tests

The initial diagnosis is often made based on the history and clinical findings. Common laboratory and diagnostic studies ordered for the assessment of allergic rhinitis may include:

- Nasal smear (positive for eosinophilia)
- Positive allergy skin test
- Positive RAST

To distinguish between the causes of nasal congestion, refer to Comparison Chart 39.1.

Nursing Management

In addition to the nursing diagnoses and related interventions discussed in the Nursing Care Plan for disorders of the nose, mouth, and throat, interventions common to allergic rhinitis follow.

Maintaining Patent Airway

The continual nasal obstruction that occurs with allergic rhinitis can be very problematic for some children. Performing nasal washes with normal saline may keep the nasal mucus from becoming thickened. Thickened, immobile secretions often lead to a secondary bacterial infection. The nasal wash also decongests the nose, allowing for improved nasal airflow. Anti-inflammatory (corticosteroid) nasal sprays can decrease the inflammatory response to allergens. A mast cell stabilizing nasal spray such as cromolyn sodium may decrease the intensity and frequency of allergic responses. Oral antihistamines are now available in once-daily dosing, providing convenience for the family. Some children may benefit from a combined antihistamine/nasal decongestant if nasal congestion is significant. Leukotriene modifiers such as montelukast may also be beneficial for some children (Banasiak & Meadows-Oliver, 2005).

Providing Family Education

One of the most important tools in the treatment of allergic rhinitis is learning to avoid known allergens. Teaching Guidelines 39.4 gives information on educating families about avoidance of allergens. Children may be referred to a specialist for allergen desensitization (allergy shots). Products helpful with control of allergies are available from a number of vendors, such as www.onlineallergyrelief.com.

ASTHMA

Asthma is a chronic inflammatory airway disorder characterized by airway hyperresponsiveness, airway edema, and mucus production. Airway obstruction resulting from asthma might be partially or completely reversed. Severity ranges from long periods of control with infrequent acute exacerbations in some children to the presence of persistent daily symptoms in others (Kieckhefer & Ratcliffe, 2004). It is the most common chronic illness of childhood and affects about 9 million American children (Kumar et al., 2005). A small percentage of children with asthma account for a large percentage of health care use and expense (Wakefield et al., 2005a, 2005b). Asthma accounts for about 14 million lost school days per year and a significant number of lost workdays on the part of parents (Rhee et al., 2007). The incidence and severity of asthma are increasing; this might be attributed to increased urbanization, increased air pollution, and more accurate diagnosis.

Severity ranges from symptoms associated only with vigorous activity (exercise-induced bronchospasm) to daily symptoms that interfere with quality of life. Table 39.4 discusses classification of asthma severity. Though uncommon, childhood death related to asthma is also on the rise worldwide. Air pollution, allergens, family history, and viral infections might all play a role in asthma. Many

TEACHING GUIDELINES 39.4

Controlling Exposure to Allergens

Tobacco

- Avoid all exposure to tobacco smoke.
- If parents cannot quit, they must not smoke inside the home or car.

Dust Mites

- Use pillow and mattress covers.
- Wash sheets, pillowcases, and comforters once a week in 130° F water.
- Use blinds rather than curtains in bedroom.
- Remove stuffed animals from bedroom.
- Reduce indoor humidity to <50%.
- Remove carpet from bedroom.
- Clean solid-surface floors with wet mop each week.

Pet Dander

- Remove pets from home permanently.
- If unable to remove them, keep them out of bedroom and off carpet and upholstered furniture.

Cockroaches

- Keep kitchen very clean.
- Avoiding leaving food or drinks out.
- Use pesticides if necessary, but ensure that the asthmatic child is not inside the home when the pesticide is sprayed.

Indoor Molds

- Repair water leaks.
- Use dehumidifier to keep basement dry.
- Reduce indoor humidity to <50%.

Outdoor Molds, Pollen, and Air Pollution

- Avoid going outdoors when mold and pollen counts are high.
- Avoid outdoor activity when pollution levels are high.

TABLE 39.4 ASTHMA SEVERITY CLASSIFICATION IN CHILDREN NOT TAKING LONG-TERM CONTROL MEDICATIONS

Classification	Symptoms	Lung Function	Interference with Normal Activity	Short-Acting Beta2-Agonist Use for Symptom Control
Intermittent	• 1 or 2 times a week • Nighttime symptoms 1 or 2 times a month	FEV 80% or more of predicted	None	1 or 2 days per week
Mild persistent	• Symptoms more than twice a week but less than once a day • Nighttime symptoms 3 or 4 times a month	FEV 80% or more of predicted, variability	Minor limitation	Greater than twice per week, but not more than once a day
Moderate persistent	• Daily symptoms • Nighttime symptoms >1 time a week, but not nightly	FEV 60% to 80% of predicted	Some limitation	Daily
Severe persistent	• Throughout the day • Nighttime symptoms often 7 times per week	FEV less than 60% of predicted	Extremely limited	Several times per day

FEV, forced expiratory volume.

HEALTHY PEOPLE 2010

Objective	Significance
Reduce asthma deaths, hospitalizations for asthma, and hospital emergency department visits for asthma.	• Provide appropriate education and triage to families of children with asthma, particularly when the child is experiencing symptoms or a decreased peak flow rate.

children with asthma also have gastroesophageal disease, though the relationship between the two diseases is not clearly understood.

A significant long-term complication, chronic airway remodeling, may result from recurrent asthma exacerbation and inflammation. This process involves structural changes such as thickening of the sub-basement membrane, subepithelial fibrosis, airway smooth muscle hypertrophy and hyperplasia, blood vessel proliferation and dilation, and mucous gland hyperplasia and hypersecretion (NAEPP, 2007). In some individuals with poorly controlled asthma, these changes may be permanent, resulting in decreased responsiveness to therapy. Children with asthma are also more susceptible to serious bacterial and viral respiratory infections. Acute complications also include status asthmaticus and respiratory failure.

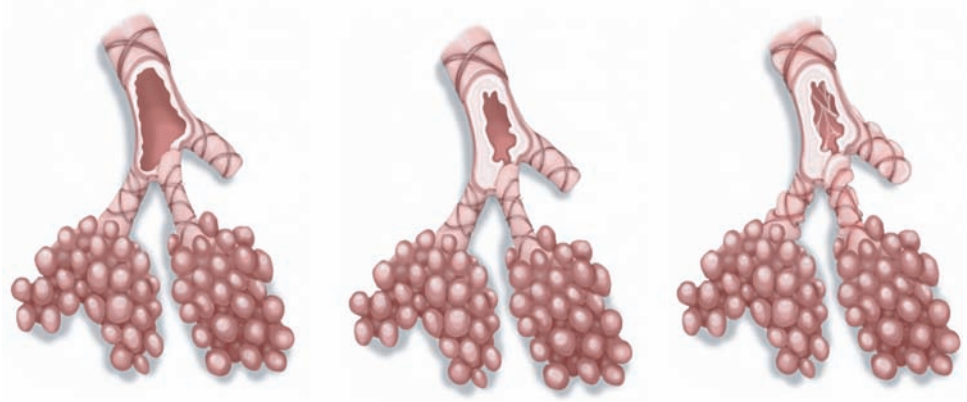
Pathophysiology

In asthma, the inflammatory process contributes to increased airway activity. Thus, control or prevention of inflammation is the core of asthma management. Asthma results from a complex variety of responses in relation to a trigger. When the process begins, mast cells, T lymphocytes, macrophages, and epithelial cells are involved in the release of inflammatory mediators. Eosinophils and neutrophils migrate to the airway, causing injury. Chemical mediators such as leukotrienes, bradykinin, histamine, and platelet-activating factor also contribute to the inflammatory response. The presence of leukotrienes contributes to prolonged airway constriction (Banasiak & Meadows-Oliver, 2005). Autonomic neural control of airway tone is affected, airway mucus secretion is increased, mucociliary function changes, and airway smooth muscle responsiveness increases (Kiecheter & Ratcliffe, 2004). As a result, acute bronchoconstriction, airway edema, and mucus plugging occur (Fig. 39.12).

In most children, this process is considered reversible and until recently it was not considered to have long-standing effects on lung function. Current research and scientific thought, however, recognize the concept of airway remodeling. Airway remodeling occurs as a result of chronic inflammation of the airway. Following the acute response to a trigger, continued allergen response results in a chronic phase. During this phase, the epithelial cells are denuded and the influx of inflammatory cells into the airway continues. This results in structural changes of the airway that are irreversible, and further loss of pulmonary function might occur (Kiecheter & Ratcliffe, 2004).

Therapeutic Management

Current goals of medical therapy are avoidance of asthma triggers and reduction or control of inflammatory episodes. The most recent recommendations by the National Asthma Education and Prevention Program (2007) suggest a stepwise approach to medication management as well as control of environmental factors (allergens) and comorbid conditions that affect asthma. The NAEPP guidelines stress periodic assessment of asthma control. Treatment decisions may then be made based on the indi-



Normal airway | Airway with inflammation | Airway with inflammation, bronchospasm, and mucus production

FIGURE 39.12 Note airway edema, mucus production, and bronchospasm occurring with asthma.

vidual's level of asthma control, rather than on the severity at diagnosis.

The stepwise approach to asthma treatment involves increasing medications as the child's condition worsens, then backing off treatment as he or she improves (Table 39.5). Bronchodilators may be used in the acute treatment of bronchoconstriction or in the long-acting form to prevent bronchospasm. Exercise-induced bronchospasm may occur in any child with asthma or as the only symptom in the child with mild intermittent asthma. Most children may avoid exercise-induced bronchospasm by using a longer warm-up period prior to vigorous exercise and, if necessary, inhaling a short-acting bronchodilator just prior to exercise. Long-term prevention usually involves inhaled steroids. Leukotriene modifiers may be used as an alternative but are not preferred for mild persistent asthma (NAEPP, 2007).

TABLE 39.5 STEPWISE APPROACH TO ASTHMA MANAGEMENT

All patients: patient education, environmental control, and management of comorbidities at each step. Consider referral to asthma specialist at step 3. (Step 2 and above are persistent asthma.)

Step 1 (intermittent asthma)
Preferred: short-acting beta2-agonist PRN

Step 2
Preferred: low-dose inhaled corticosteroid
Alternative: cromolyn or leukotriene modifier

Step 3
Preferred: medium-dose inhaled corticosteroid (all ages) OR low-dose inhaled corticosteroid and leukotriene modifier or long-acting beta2-agonist (children over 4 yrs)

Step 4
Preferred: medium-dose inhaled corticosteroids and long-acting beta2-agonist (can use leukotriene modifier in children under 4 yrs)

Step 5
Preferred: high-dose inhaled corticosteroids and long-acting beta2-agonist (or leukotriene modifier or theophylline)

Step 6
Preferred: high-dose inhaled corticosteroids, long-acting beta2-agonist and oral systemic corticosteroids

Adapted from National Asthma Education and Prevention Program. (2007). *Expert panel report 3: Guidelines for the diagnosis and management of asthma* (NIH Publication No. 07-4051). Bethesda, MD: National Institutes of Health, National Heart, Lung and Blood Institute. These recommendations are intended to be used as a guide in individualized asthma care.

HEALTHY PEOPLE 2010

Objective	Significance
Reduce activity limitations among persons with asthma. (Developmental) Reduce the number of school days or workdays missed by persons with asthma. Increase the proportion of persons with asthma who receive formal patient education, including information about community and self-help resources, as an essential part of the management of their condition.	• Encourage appropriate physical activity in children with asthma. • Provide extensive education to children and families about peak flow meter use and its meaning, maintenance and rescue medications, symptoms of asthma exacerbation, and a written plan for how to "step up" and "step down" asthma management. • Refer children and their families to local or Internet resources and support groups. • Refer families to formal classes on asthma education.

▶ *Take* NOTE!

By the end of 2008, all metered-dose inhalers using chlorofluorocarbon (CFC) as the propellant should be off the market. Environmentally friendly formulations of hydrofluoroalkane (HFA) will be used in all metered-dose inhalers by that time (Bederka, 2006).

Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1222. Assessment findings pertinent to asthma are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Cough, particularly at night: hacking cough that is initially nonproductive, becoming productive of frothy sputum
- Difficulty breathing: shortness of breath, chest tightness or pain, dyspnea with exercise
- Wheezing

Explore the child's current and past medical history for risk factors such as:

- History of allergic rhinitis or atopic dermatitis
- Family history of atopy (asthma, allergic rhinitis, atopic dermatitis)

- Recurrent episodes diagnosed as wheezing, bronchiolitis, or bronchitis
- Known allergies
- Seasonal response to environmental pollen
- Tobacco smoke exposure
- Poverty

Physical Examination

Physical examination of the child with asthma includes inspection, auscultation, and percussion.

Inspection

Observe the child's general appearance and color. During mild exacerbations, the child's color might remain pink, but as the child worsens, cyanosis might result. Work of breathing is variable. Some children present with mild retractions, while others demonstrate significant accessory muscle use and eventually head-bobbing if not effectively treated. The child may appear anxious and fearful or may be lethargic and irritable. An audible wheeze might be present. Children with persistent severe asthma may have a barrel chest and routinely demonstrate mildly increased work of breathing.

Auscultation and Percussion

A thorough assessment of lung fields is necessary. Wheezing is the hallmark of airway obstruction and might vary throughout the lung fields. Coarseness might also be present. Assess the adequacy of aeration. Breath sounds might be diminished in the bases or throughout. A quiet chest in an asthmatic child can be an ominous sign. With severe airway obstruction, air movement can be so poor that wheezes might not be heard upon auscultation. Percussion may yield hyperresonance.

Laboratory and Diagnostic Tests

Laboratory and diagnostic studies commonly ordered for the assessment of asthma include:

- Pulse oximetry: oxygen saturation may be significantly decreased or normal during a mild exacerbation
- Chest x-ray: usually reveals hyperinflation
- Blood gases: might show carbon dioxide retention and hypoxemia
- Pulmonary function tests (PFTs): can be very useful in determining the degree of disease but are not useful during an acute attack. Children as young as 5 or 6 years might be able to comply with spirometry.
- Peak expiratory flow rate (PEFR): is decreased during an exacerbation
- Allergy testing: skin test or RAST can determine allergic triggers for the asthmatic child

Nursing Management

Initial nursing management of the child with an acute exacerbation of asthma is aimed at restoring a clear airway and effective breathing pattern as well as promoting adequate oxygenation and ventilation (gas exchange). Refer to the Nursing Care Plan. Additional considerations are reviewed below.

Educating the Child and Family

Asthma is a chronic illness and needs to be understood as such. Figure 39.13 displays the "Kids with Asthma Bill of Rights" developed by the American Lung Association. Teach families of children with asthma, and the children themselves, how to care for the disease. Symptom-free periods (often very long) are interspersed with episodes of exacerbation. Parents and children often do not understand the importance of maintenance medications for long-term control. They may view the episodes of exacerbation (sometimes requiring hospitalization or emergency room visits) as an acute illness and are simply relieved when they are over. Frequently during the periods between acute episodes, children are viewed as disease-free and long-term maintenance schedules are abandoned. The prolonged inflammatory process occurring in the absence of symptoms, primarily in children with moderate to severe asthma, can lead to airway remodeling and eventual irreversible disease.

Each child should have a management plan in place to determine when to step up or step down treatment. Figure 39.14 provides an example of a written format that may be helpful to families in the management of asthma. This written action plan should also be kept on file at the child's school, and relief medication should be available to the child at all times. Children who experience exercise-induced bronchospasm may still participate in physical education or athletics but may need to be allowed to use their medicine before the activity. Provide appropriate education to the child and family based on the child's individualized stepwise treatment plan. Stress the concept of maintenance medications for the prevention of future serious disease in addition to controlling or preventing current symptoms.

Educate families and children on the appropriate use of nebulizers, metered-dose inhalers, spacers, dry-powder inhalers, and Diskus, as well as the purposes, functions, and side effects of the medications they deliver. Require return demonstrations of equipment use to ensure that children and families can use the equipment properly (Teaching Guidelines 39.5).

▶ *Take* NOTE!

The NAEPP recommends use of a spacer or holding chamber with metered-dose inhalers to increase the bioavailability of medication in the lungs.

Asthma Action Plan

AMERICAN LUNG ASSOCIATION.

General Information:

- Name _____
- Emergency contact _____ Phone numbers _____
- Physician/Health Care Provider _____ Phone numbers _____
- Physician Signature _____ Date _____

Severity Classification	Triggers	Exercise
○ Mild Intermittent ○ Moderate Persistent ○ Mild Persistent ○ Severe Persistent	○ Colds ○ Smoke ○ Weather ○ Exercise ○ Dust ○ Air pollution ○ Animals ○ Food ○ Other _____	1. Pre-medication (how much and when) _____ 2. Exercise modifications _____

Green Zone: Doing Well

Peak Flow Meter Personal Best =

Symptoms

- Breathing is good
- No cough or wheeze
- Can work and play
- Sleeps all night

Control Medications

Medicine	How Much to Take	When To Take It

Peak Flow Meter

More than 80% of personal best or _____

Yellow Zone: Getting Worse

Contact Physician if using quick relief more than 2 times per week.

Symptoms

- Some problems breathing
- Cough, wheeze or chest tight
- Problems working or playing
- Wake at night

Continue control medicines and add:

Medicine	How Much to Take	When To Take It

Peak Flow Meter

Between 50 to 80% of personal best or _____ to _____

IF your symptoms (and peak flow, if used) return to Green Zone after one hour of the quick relief treatment, THEN

- ○ Take quick-relief medication every 4 hours for 1 to 2 days
- ○ Change your long-term control medicines by _____
- ○ Contact your physician for follow-up care

IF your symptoms (and peak flow, if used) DO NOT return to the GREEN ZONE after 1 hour of the quick relief treatment, THEN

- ○ Take quick-relief treatment again
- ○ Change your long-term control medicines by _____
- ○ Call your physician/Health Care Provider within _____ hours of modifying your medication routine

Red Zone: Medical Alert

Ambulance/Emergency Phone Number:

Symptoms

- Lots of problems breathing
- Cannot work or play
- Getting worse instead of better
- Medicine is not helping

Continue control medicines and add:

Medicine	How Much to Take	When To Take It

Peak Flow Meter

Between 0 to 50% of personal best or _____ to _____

Go to the hospital or call for an ambulance if

- ○ Still in the red zone after 15 minutes
- ○ If you have not been able to reach your physician/health care provider for help
- ○ _____

Call an ambulance immediately if the following danger signs are present

- ○ Trouble walking/talking due to shortness of breath
- ○ Lips or fingernails are blue

FIGURE 39.14 Asthma action plan.

TEACHING GUIDELINES 39.5

Using Asthma Medication Delivery Devices

Nebulizer

1. Plug in the nebulizer and connect the air compressor tubing.

2. Add the medication to the medicine cup.

3. Attach the mask or the mouthpiece and hose to the medicine cup.

4. Place the mask on the child OR

5. Instruct the child to close the lips around the mouthpiece and breathe through the mouth.

6. After use, wash the mouthpiece and medicine cup with water and allow to air dry.

Metered-Dose Inhaler

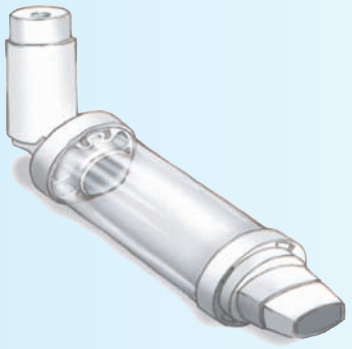
1. Shake the inhaler and take off the cap.

(continued)

TEACHING GUIDELINES 39.5 (continued)

Using Asthma Medication Delivery Devices

2. Attach the inhaler to the spacer or holding chamber.



3. Breathe out completely.
4. Put the spacer mouthpiece in the mouth (or place the mask over the child's nose and mouth, ensuring a good seal).

5. Compress the inhaler and inhale slowly and deeply. Hold the breath for a count of 10.

Diskus

1. Hold the Diskus in a horizontal position in one hand and push the thumb grip with the thumb of your other hand away from you until mouthpiece is exposed.

2. Push the lever until it clicks (the dose is now loaded).

3. Breathe out fully.
4. Place your mouth securely around the mouthpiece and breathe in fully and quickly through your mouth.
5. Remove the Diskus, hold the breath for 10 seconds, and then breathe out.

TEACHING GUIDELINES 39.5 (continued)

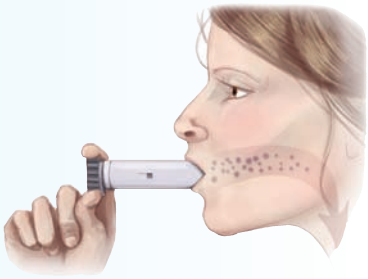
Using Asthma Medication Delivery Devices

Turbuhaler

1. Hold the Turbuhaler upright. Load the dose by twisting the brown grip fully to the right.

2. Then twist it to the left until you hear it click.

3. Breathe out fully.
4. Holding the Turbuhaler horizontally, place the mouth firmly around the mouthpiece and inhale deeply and forcefully.



5. Remove the Turbuhaler from the mouth and then breathe out.

In children who have more severe asthma, the NAEPP recommends the use of the peak expiratory flow rate (PEFR) to determine daily control. PEFR measurements obtained via a home peak flow meter can be very helpful as long as the meter is used appropriately; Teaching Guidelines 39.6 gives instructions on peak flow meter use. The child's "personal best" is determined collaboratively with the health care practitioner during a symptom-free period. PEFR is measured daily at home using the peak flow meter. The asthma management plan then gives specific instructions based on the PEFR measurement (Table 39.6).

TEACHING GUIDELINES 39.6

Using a Peak Flow Meter

- Slide the arrow down to "zero."
- Stand up straight.
- Take a deep breath and close the lips tightly around the mouthpiece.
- Blow out hard and fast.
- Note the number the arrow moves to.
- Repeat three times and record the highest reading.
- Keep a record of daily readings, being sure to measure peak flow at the same time each day.

Source: Data from the American Lung Association.

▶ *Take* NOTE!

Young children with asthma receiving inhaled medications via a nebulizer should use a snugly fitting mask to ensure accurate deposition of medication to the lungs. "Blow-by" via nebulizer should be discouraged, as medication delivery is variable and unreliable.

Avoidance of allergens is another key component of asthma management. Avoiding known triggers helps to prevent exacerbations as well as long-term inflammatory changes. This can be a difficult task for most families, particularly if the affected child suffers from several allergies.

TABLE 39.6 ASSESSMENT OF PEAK EXPIRATORY FLOW RATE (PEFR)

Zone*	PEFR	Symptoms	Action
Green: Good control	>80% personal best	None	Take usual medications.
Yellow: Caution	50% to 80% personal best	Possibly present	Take short-acting inhaled beta2-agonist right away. Talk to your health care provider.
Red: Medical alert	<50% personal best	Usually present	Take short-acting inhaled beta2-agonist right away. Go to office or emergency department.

*The National Asthma Education and Prevention Program recommended the "traffic light" approach for educating individuals on PEFRs and management plans.

Teaching Guidelines 39.4 outlines strategies for allergen avoidance.

Research has found a lag in parent/child education in relation to asthma management (Horner, 2004). Asthma education is not limited to the hospital or clinic setting. Nurses can become involved in community asthma education: community-centered education in schools, churches, and daycare centers or through peer educators has been shown to be effective. Education should include pathophysiology, asthma triggers, and prevention and treatment strategies. With such a large number of children affected with this chronic disease, community education has the potential to make a broad impact.

School nurses must also become experts in asthma management as well as being committed to ongoing education of the child and family. Resources for schools include:

- Open Airways for Schools: an educational program presented by the American Lung Association or its local chapter, focusing on increasing asthma awareness and compliance with asthma action plans and decreasing asthma emergencies. Contact the local lung association or call 1-800-LUNG-USA.
- Asthma and Allergies at School: a kit available from AANMA at www.breatherville.org/schoolhouse or 1-800-878-4403.
- Healthy School Environments Assessment Tool: http://www.epa.gov/schools/

▶ ***Take*** *NOTE!*

Exposure to cigarette smoke increases the need for medications in children with asthma as well as the frequency of asthma exacerbations. Both indoor air quality and environmental pollution contribute to asthma in children.

Promoting the Child's Self-Esteem

Fear of an exacerbation and feeling "different" from other children can harm a child's self-esteem. In qualitative research studies, children have made such statements as "my body shuts down" and "I feel like I'm going to die" (Yoos et al., 2005). The fatigue and fear associated with chronic asthma may reduce the child's confidence and sense of control over his or her body and life. In addition to coping with a chronic illness, the asthmatic child often also has to cope with school-related issues. Moodiness, acting out, and withdrawal correlate with increases in school absence, which can contribute to poor school performance. To live in fear of an exacerbation or to be unable to participate in activities affects the child's self-esteem.

Through education and support, the child can gain a sense of control. Children need to learn to master their disease. Accurate evaluation of asthma symptoms and improvement of self-esteem may help the child to experience less panic with an acute episode. Improved self-esteem might also help the child cope with the disease in general and with being different from his or her peers. The school-age child has the cognitive ability to begin taking responsibility for asthma management, with continued involvement on the part of the parents. Transferring control of asthma care to the child is an important developmental process that will increase the child's feeling of control over the illness (Buford, 2004).

Promoting Family Coping

Parent denial is an issue in many families. The family, through education and encouragement, can become the experts on the child's illness as well as advocates for the child's well-being. The resilient child is better able to cope with the challenges facing him or her, including asthma. Cohesiveness and warmth in the family environment can improve a child's resiliency as well as contribute to family hardiness. Parents need to be allowed to ask questions and voice their concerns. A nurse who understands the family's issues and concerns is better able to plan for support and education. Provide culturally sensitive education

and interventions that focus on increasing the family's commitment to and control of asthma management. As the child and parents become confident in their ability to recognize asthma symptoms and cope with asthma and its periodic episodes, the family's ability to cope will improve (Svavarsdottir & Rayens, 2005).

CHRONIC LUNG DISEASE

Chronic lung disease (formerly termed bronchopulmonary dysplasia) is often diagnosed in infants who have experienced RDS and continue to require oxygen at 28 days of age. It is a chronic respiratory condition seen most commonly in premature infants. It results from a variety of factors, including pulmonary immaturity, acute lung injury, barotrauma, inflammatory mediators, and volutrauma. Epithelial stretching, macrophage and polymorphonuclear cell invasion, and airway edema affect the growth and development of lung structures. Cilia loss and airway lining denudation reduce the normal cleansing abilities of the lung. The number of normal alveoli is reduced by one third to one half. Lower birthweights, white race, and male gender pose increased risk for development of chronic lung disease. Complications include pulmonary artery hypertension, cor pulmonale, congestive heart failure, and severe bacterial or viral pneumonia. (Harvey, 2004; Stoll & Kliegman, 2004).

Anti-inflammatory inhaled medications are used for maintenance, and short-acting bronchodilators are used as needed for wheezing episodes. Supplemental long-term oxygen therapy may be required in some infants.

Nursing Assessment

Tachypnea and increased work of breathing are characteristic of chronic lung disease. After discharge from the NICU, these symptoms can continue. Exertion such as activity or oral feeding can cause dyspnea to worsen. Failure to thrive might also be evident. Auscultation might reveal breath sounds that are diminished in the bases. These infants have reactive airway episodes, so wheezing might be present during times of exacerbation. If fluid overload develops, rales may be heard.

Nursing Management

If the infant is oxygen-dependent, provide education to the parents about oxygen tanks, nasal cannula use, pulse oximetry use, and nebulizer treatments. Often these children require increased-calorie formulas to grow adequately. Fluid restrictions and/or diuretics are necessary in some infants. Follow-up echocardiograms might be used to determine resolution of pulmonary artery hypertension prior to weaning from oxygen. Encourage developmentally appropriate activities. It might be difficult for the oxygen-dependent infant or toddler to reach gross motor milestones or explore the environment because the length of the oxygen tubing limits him or her.

Parental support is also a key nursing intervention. After a long and trying period of ups and downs with their newborn in the intensive care unit, parents find themselves exhausted caring for their medically fragile infant at home.

CYSTIC FIBROSIS

Cystic fibrosis is an autosomal recessive disorder that occurs about once in every 3,300 live white births and about once in every 16,000 live black births (Boat, 2004). A deletion occurring on the long arm of chromosome 7 at the cystic fibrosis transmembrane regulator (CFTR) is the responsible gene mutation. DNA testing can be used prenatally and in newborns to identify the presence of the mutation. The American College of Obstetrics and Gynecology currently recommends screening for cystic fibrosis to any person seeking preconception or prenatal care. At present, 11 states include testing for cystic fibrosis as part of newborn screening (Gross et al., 2004).

Cystic fibrosis is the most common debilitating disease of childhood among those of European descent. Medical advances in recent years have greatly increased the length and quality of life for affected children: about 50% now live past the age of 30 years (Boat, 2004), and many live a high-quality life into their 40s (Carpenter & Narsavage, 2004). Complications include hemoptysis, pneumothorax, bacterial colonization, cor pulmonale, volvulus, intussusception, intestinal obstruction, rectal prolapse, gastroesophageal reflux disease, diabetes, portal hypertension, liver failure, gallstones, and decreased fertility.

Therapeutic Management

Therapeutic management of cystic fibrosis is aimed toward minimizing pulmonary complications, maximizing lung function, preventing infection, and facilitating growth. All children with cystic fibrosis who have pulmonary involvement require chest physiotherapy with postural drainage several times daily to mobilize secretions from the lungs. Physical exercise is encouraged. Recombinant human DNase (Pulmozyme) is given daily using a nebulizer to decrease sputum viscosity and help clear secretions. Inhaled bronchodilators and anti-inflammatory agents are prescribed for some children. Aerosolized antibiotics are often prescribed and may be given at home as well as in the hospital. Choice of antibiotic is determined by sputum culture and sensitivity results. Pancreatic enzymes and supplemental fat-soluble vitamins are prescribed to promote adequate digestion and absorption of nutrients and optimize nutritional status. Increased-calorie, high-protein diets are recommended, and sometimes supplemental high-calorie

formula, either orally or via feeding tube, is needed. Some children require total parenteral nutrition to maintain or gain weight (McMullen, 2004). Lung transplantation has been successful in some children with cystic fibrosis.

Pathophysiology

In cystic fibrosis, the CFTR mutation causes alterations in epithelial ion transport on mucosal surfaces, resulting in generalized dysfunction of the exocrine glands. The epithelial cells fail to conduct chloride, and water transport abnormalities occur. This results in thickened, tenacious secretions in the sweat glands, gastrointestinal tract, pancreas, respiratory tract, and other exocrine tissues. The increased viscosity of these secretions makes them difficult to clear. The sweat glands produce a larger amount of chloride, leading to a salty taste of the skin and alterations in electrolyte balance and dehydration. The pancreas, intrahepatic bile ducts, intestinal glands, gallbladder, and submaxillary glands become obstructed by viscous mucus and eosinophilic material. Pancreatic enzyme activity is lost and malabsorption of fats, proteins, and carbohydrates occurs, resulting in poor growth and large, malodorous stools. Excess mucus is produced by the tracheobronchial glands. Abnormally thick mucus plugs the small airways, and then bronchiolitis and further plugging of the airways occur. Secondary bacterial infection with *Staphylococcus aureus, Pseudomonas aeruginosa,* and *Burkholderia cepacia* often occurs. This contributes to obstruction and inflammation, leading to chronic infection, tissue damage, and respiratory failure. Nasal polyps and recurrent sinusitis are common. Boys have tenacious seminal fluid and experience blocking of the vas deferens, often making them infertile. In girls, thick cervical secretions might limit penetration of sperm (Boat, 2004; Simpson & Ivey, 2005). Table 39.7 gives further details of the pathophysiology

TABLE 39.7 Pathophysiology of Cystic Fibrosis and Resultant Respiratory and Gastrointestinal Clinical Manifestations

Defect in the CFTR Gene Affects:	Pathophysiology	Clinical Manifestations
Respiratory tract	• Infection leads to neutrophilic inflammation. • Cleavage of complement receptors and immunoglobin G leads to opsonophagocytosis failure. • Chemoattractant interleukin-8 and elastin degradase contribute to inflammatory response. • Thick, tenacious sputum that is chronically colonized with bacteria results. • Air trapping related to airway obstruction • Pulmonary parenchyma is eventually destroyed.	• Airway obstruction • Difficulty clearing secretions • Respiratory distress and impaired gas exchange • Chronic cough • Barrel-shaped chest • Decreased pulmonary function • Clubbing • Recurrent pneumonia • Hemoptysis • Pneumothorax • Chronic sinusitis • Nasal polyps • Cor pulmonale (right-sided heart failure)
Gastrointestinal tract	• Decreased chloride and water secretion into the intestine (causing dehydration of the intestinal material) and into the bile ducts (causing increased bile viscosity) • Reduced pancreatic bicarbonate secretion • Hypersecretion of gastric acid • Insufficiency of pancreatic enzymes necessary for digestion and absorption • Pancreas secretes thick mucus.	• Meconium ileus • Retention of fecal matter in distal intestine, resulting in vomiting, abdominal distention and cramping, anorexia, right lower quadrant pain • Sludging of intestinal contents may lead to fecal impaction, rectal prolapse, bowel obstruction, intussusception. • Obstructive cirrhosis with esophageal varices, and splenomegaly • Gallstones • Gastroesophageal reflux disease (compounded by postural drainage with chest physiotherapy) • Inadequate protein absorption • Altered absorption of iron and vitamins A, D, E, and K • Failure to thrive • Hyperglycemia and development of diabetes later in life

and resulting respiratory and gastrointestinal clinical manifestations of cystic fibrosis.

Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1222. Assessment findings pertinent to cystic fibrosis are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history in the undiagnosed child might include:

- A salty taste to the child's skin (resulting from excess chloride loss via perspiration)
- Meconium ileus or late, difficult passage of meconium stool in the newborn period
- Abdominal pain or difficulty passing stool (infants or toddlers might present with intestinal obstruction or intussusception at the time of diagnosis)
- Bulky, greasy stools
- Poor weight gain and growth despite good appetite
- Chronic or recurrent cough and/or upper or lower respiratory infections

Children known to have cystic fibrosis are often admitted to the hospital for pulmonary exacerbations or other complications of the disease. The health history should include questions related to:

- Respiratory status: has cough, sputum production, or work of breathing increased?
- Appetite and weight gain
- Activity tolerance
- Increased need for pulmonary or pancreatic medications
- Presence of fever
- Presence of bone pain
- Any other changes in physical state or medication regimen

Physical Examination

The physical examination includes inspection, auscultation, percussion, and palpation.

Inspection

Observe the child's general appearance and color. Check the nasal passages for polyps. Note respiratory rate, work of breathing, use of accessory muscles, position of comfort, frequency and severity of cough, and quality and quantity of sputum produced. The child with cystic fibrosis often has a barrel chest (anterior–posterior diameter approximates transverse diameter) (Fig. 39.15). Clubbing of the nail beds might also be present. Note whether rectal prolapse is present. Does the child appear small or thin for his or her age? The child might have a protuberant abdomen and thin extremities, with decreased amounts of subcutaneous fat. Observe for the presence of edema (sign of cardiac or liver failure). Note distended neck veins or the presence of a heave (signs of cor pulmonale).

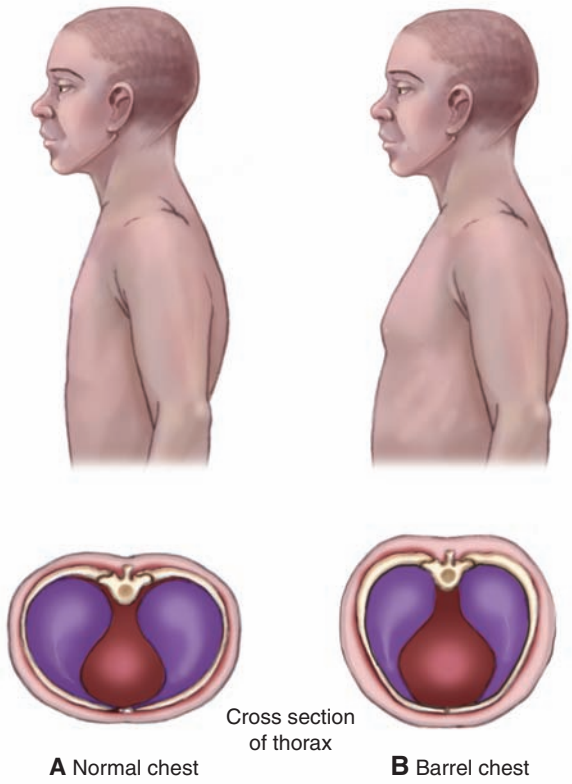


Figure 39.15 (**A**) Normal chest shape—transverse diameter is greater than anterior–posterior diameter. (**B**) Barrel chest—transverse diameter equals anterior–posterior diameter.

Auscultation

Auscultation may reveal a variety of adventitious breath sounds. Fine or coarse crackles and scattered or localized wheezing might be present. With progressive obstructive pulmonary involvement, breath sounds might be diminished. Tachycardia might be present. Note the presence of a gallop (might occur with cor pulmonale). Note the adequacy of bowel sounds.

Percussion

Percussion over the lung fields usually yields hyperresonance due to air trapping. Diaphragmatic excursion might be decreased. Percussion of the abdomen might reveal dullness over an enlarged liver or mass related to intestinal obstruction.

Palpation

Palpation might yield a finding of asymmetric chest excursion if atelectasis is present. Tactile fremitus may be decreased over areas of atelectasis. Note if tenderness is present over the liver (might be an early sign of cor pulmonale).

Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the diagnosis and assessment of cystic fibrosis include:

- Sweat chloride test: considered suspicious if the level of chloride in collected sweat is above 50 mEq/L and diagnostic if the level is above 60 mEq/L (Fig. 39.16)
- Pulse oximetry: oxygen saturation might be decreased, particularly during a pulmonary exacerbation
- Chest x-ray: may reveal hyperinflation, bronchial wall thickening, atelectasis, or infiltration
- Pulmonary function tests: might reveal a decrease in forced vital capacity and forced expiratory volume, with increases in residual volume (Boat, 2004; McMullen, 2004)

Nursing Management

Management of cystic fibrosis focuses on minimizing pulmonary complications, promoting growth and development, and facilitating coping and adjustment by the child and family. In addition to the nursing diagnoses and related interventions discussed in the Nursing Care Plan for respiratory disorders, interventions common to cystic fibrosis follow.

Maintaining Patent Airway

Chest physiotherapy is often used as an adjunct therapy in respiratory illnesses, but for children with cystic fibrosis it is a critical intervention. Chest physiotherapy involves percussion, vibration, and postural drainage, and either it or another bronchial hygiene therapy must be performed several times a day to assist with mobilization of secretions. Nursing Procedure 39.2 gives instructions on the chest physiotherapy technique.

For older children and adolescents, the flutter-valve device, positive expiratory pressure therapy, or a high-frequency chest compression vest may also be used. The flutter valve device provides high-frequency oscillation to the airway as the child exhales into a mouthpiece that contains a steel ball. Positive expiratory pressure therapy involves exhaling through a flow resistor, which creates positive expiratory pressure. The cycles of exhalation are repeated until coughing yields expectoration of secretions.

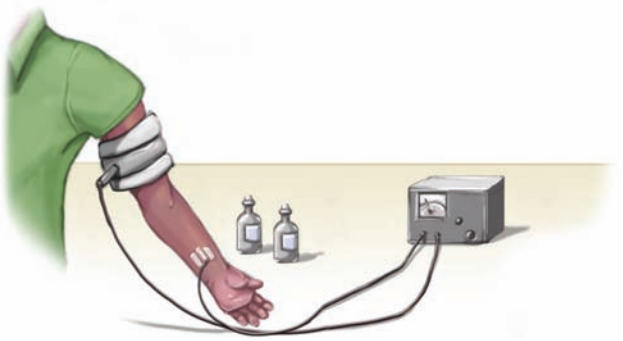

FIGURE 39.16 Sweat chloride test.

The vest airway clearance system provides high-frequency chest wall oscillation to increase airflow velocity to create repetitive cough-like shear forces and to decrease the viscosity of secretions (Chatburn, 2007). Breathing exercises are also helpful in promoting mucus clearance. Encourage physical exercise, as it helps to promote mucus secretion as well as providing cardiopulmonary conditioning. Ensure that Pulmozyme is administered, as well as inhaled bronchodilators and anti-inflammatory agents if prescribed.

Preventing Infection

Vigorous pulmonary hygiene for mobilization of secretions is critical to prevent infection. Aerosolized antibiotics can be given at home as well as in the hospital. Children with frequent or severe respiratory exacerbations might require lengthy courses of intravenous antibiotics.

Maintaining Growth

Pancreatic enzymes must be administered with all meals and snacks to promote adequate digestion and absorption of nutrients. The number of capsules required depends on the extent of pancreatic insufficiency and the amount of food being ingested. The dosage can be adjusted until an adequate growth pattern is established and the number of stools is consistent at one or two per day. Children will need additional enzyme capsules when high-fat foods are being eaten. In the infant or young child, the enzyme capsule can be opened and sprinkled on cereal or applesauce. A well-balanced, high-calorie, high-protein diet is necessary to ensure adequate growth. Some children require up to 1.5 times the recommended daily allowance of calories for children their age. A number of commercially available nutritional formulas and shakes are available for diet supplementation.

In infants, breastfeeding should be continued with enzyme administration. Some infants will require fortification of breast milk or supplementation with high-calorie formulas. Commercially available infant formulas can continue to be used for the formula-fed infant and can be mixed to provide a larger amount of calories if necessary. Supplementation with vitamins A, D, E, and K is necessary. Administer gavage feedings or total parenteral nutrition as prescribed to provide for adequate growth.

Promoting Family Coping

Cystic fibrosis is a serious chronic illness that requires daily interventions. It can be hard to maintain a schedule that requires pulmonary hygiene several times daily as well as close attention to appropriate diet and enzyme supplementation. Adjusting to the demands that the illness places on the child and family is difficult. Continual adjustments within the family must occur. Children are frequently hospitalized, and this may place an additional strain on the family and its finances. Children with cystic fibrosis may express fear or feelings of isolation, and siblings may be worried or jealous (Carpenter & Narsavage, 2004). The

Nursing Procedure 39.2

Performing Chest Physiotherapy

1. Provide percussion via a cupped hand or an infant percussion device. Appropriate percussion yields a hollow sound, not a slapping sound.

2. Percuss each segment of the lung for 1 to 2 minutes.

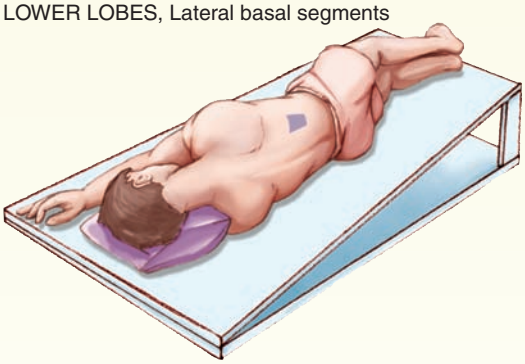
POSITION #8 & 9
LOWER LOBES, Lateral basal segments



POSITION #10
LOWER LOBES, Superior segments

3. Place the ball of the hand on the lung segment, keeping the arm and shoulder straight. Vibrate by tensing and relaxing your arms during the child's exhalation. Vibrate each lung segment for at least five exhalations.
4. Encourage the child to deep breathe and cough.
5. Change drainage positions and repeat percussion and vibration.

family should be encouraged to lead a normal life through involvement in activities and school attendance during periods of wellness.

▶ *Take* NOTE!

Massage therapy performed by the parent, nurse, or licensed massage therapist may help to decrease anxiety in the child with cystic fibrosis. It may have the added benefit of improving respiratory status, but it does not replace chest physiotherapy (Huth et al., 2005).

Starting at the time of diagnosis, families often demonstrate significant stress as the severity of the diagnosis and the significance of disease chronicity become real for them. The family should be involved in the child's care from the time of diagnosis, whether in the outpatient setting or in the hospital. Ongoing education about the illness and its treatments is necessary. Once the initial shock of diagnosis has passed and the family has adjusted to initial care, the family usually learns how to manage the requirements of care. Powerlessness gives way to adaptation. As family members become more comfortable with their understanding of the illness and the required treatments, they will eventually become the experts on the child's care. It is important for the nurse to recognize and respect the family's changing needs over time.

Providing daily intense care can be tiring, and noncompliance on the part of the family or child might occur as a result of this fatigue. Overvigilance may also occur as parents attempt to control the difficult situation and protect the child. Families welcome support and encouragement. Most families eventually progress past the stages of fear, guilt, and powerlessness to a way of living that is different than what they anticipated but is something that they can manage.

Refer parents to a local support group for families of children with cystic fibrosis. The Cystic Fibrosis Foundation has chapters throughout the United States (www.cff.org). Additional resources can be found at www.cystic fibrosis.com, www.cfri.org, and www.cfww.org.

Parents of children with a terminal illness might face the death of their child at an earlier age than expected. Assisting with anticipatory grieving and making decisions related to end-of-life care are other important nursing interventions.

Preparing the Child and Family for Adulthood With Cystic Fibrosis

With current technological and medication advances, many more children with cystic fibrosis are surviving to adulthood and into their 30s and 40s. Lung transplantation is now being used in some patients with success, thus prolonging life expectancy (barring transplant complications). Children with cystic fibrosis should have the goal of independent living as an adult, as other children do. Making the transition from a pediatric medical home to an adult medical home should be viewed as a normal part of growing up, similar to completing school or finding a first job (Kennedy et al., 2007). Pediatric clinics are focused on family-centered care that heavily involves the child's parents, but adults with cystic fibrosis need a different focus, one that views them as independent adults.

Clients with cystic fibrosis can make the transition from pediatric to adult care with thoughtful preparation and coordination. They desire and deserve a smooth transition in care that will result in appropriate ongoing medical management of cystic fibrosis in an environment that is geared toward adults rather than children.

Adults with cystic fibrosis are able to find rewarding work and pursue relationships. Most men with cystic fibrosis are capable of sexual intercourse, though unable to reproduce. Females might have difficulty conceiving, and when they do they should be cautioned about the additional respiratory strain that pregnancy causes. All children of parents with cystic fibrosis will be carriers of the gene.

APNEA

Apnea is defined as absence of breathing for longer than 20 seconds; it might be accompanied by bradycardia. Sometimes apnea presents in the form of an acute life-threatening event (ALTE), an event in which the infant or child exhibits some combination of apnea, color change, muscle tone alteration, coughing, or gagging. Apnea may also occur acutely at any age as a result of respiratory distress. This discussion will focus on apnea that is chronic or recurrent in nature or that occurs as part of an ALTE.

Apnea in infants may be central (unrelated to any other cause) or may occur with other illnesses such as sepsis and respiratory infection. Apnea in newborns might be associated with hypothermia, hypoglycemia, infection, or hyperbilirubinemia. Apnea of prematurity occurs secondary to an immature respiratory system. Apnea should not be considered a predecessor to sudden infant death syndrome (SIDS). Current research has not proven this theory, and SIDS generally occurs in otherwise healthy young infants (AAP, Task Force on Sudden Infant Death Syndrome, 2005). Box 39.3 gives more information about SIDS and its prevention.

Therapeutic management of apnea varies depending on the cause. When apnea occurs as a result of another disorder or infection, treatment is directed toward that cause. In the event of apnea, stimulation may trigger the infant to take a breath. If breathing does not resume, rescue breathing or bag-valve-mask ventilation is necessary. Infants and children who have experienced an ALTE or who have chronic apnea may require ongoing cardiac/

BOX 39.3 Sudden Infant Death Syndrome (SIDS)

Definition

Sudden death of a previously healthy infant <1 year of age

Prevention

- Place all infants in the supine position to sleep (even side-lying is not as safe and is not recommended by the AAP).
- Provide a firm sleep surface and avoid soft bedding, excess covers, pillows, and stuffed animals in the crib.
- Avoid maternal prenatal smoking and exposure of the infant to second-hand smoke.
- Ensure the infant sleeps separately from the parents.
- Avoid overbundling or overdressing the infant.
- Encourage pacifier use during naps and at bedtime if the infant is receptive to it (AAP, 2005).

Support and Information

- SIDS Alliance: www.sidsalliance.org
- National Sudden Infant Death Resource Center: www.sidscenter.org
- Association for SIDS and Infant Mortality Program: www.asip1.org
- Sudden Infant Death Syndrome Network, Inc.: ds-network.org/

apnea monitoring. Caffeine or theophylline is sometimes administered, primarily in premature infants, to stimulate respirations.

Nursing Assessment

Question the parents about the infant's position and activities preceding the apneic episode. Did the infant experience a color change? Did the infant self-stimulate (breathe again on his or her own), or did he or she require stimulation from the caretaker? Assess risk factors for apnea, which may include prematurity, anemia, and history of metabolic disorders. Apnea may occur in association with cardiac or neurologic disturbances, respiratory infection, sepsis, child abuse, or poisoning.

In the hospitalized infant, note absence of respiration, position, color, and other associated findings, such as emesis on the bedclothes. If an infant who is apneic fails to be stimulated and does not breathe again, pulselessness will result.

Nursing Management

When an infant is noted to be apneic, gently stimulate him or her to take a breath again. If gentle stimulation is unsuccessful, then rescue breathing or bag-valve-mask ventilation must be started.

To avoid apnea in the newborn, maintain a neutral thermal environment. Avoid excessive vagal stimulation and taking rectal temperatures (the vagal response can cause bradycardia, resulting in apnea). Administer caffeine or theophylline if prescribed and teach families about the use of these medications.

Infants with recurrent apnea or ALTE may be discharged on a home apnea monitor (Fig. 39.17). Provide education on use of the monitor, guidance about when to notify the physician or monitor service about alarms, and training in infant CPR. The monitor is usually discontinued after 3 months without a significant event of apnea or bradycardia. In some ways the monitor gives parents peace of mind, but in others it can make them more nervous about the well-being of their child. Also, the alarm on home monitors is extremely loud and parents often go for months with inadequate sleep. Providing appropriate education to the parents about the nature of the child's disorder as well as action to take in the event of apnea may give the family a sense of mastery over the situation, thus decreasing their anxiety. Refer families to local support groups such as those offered by Parent to Parent and Parents Helping Parents.

Tracheostomy

A **tracheostomy** is an artificial opening in the airway; usually a plastic tracheostomy tube is in place to form a patent airway. Tracheostomies are performed to relieve airway obstruction, such as with **subglottic stenosis** (narrowing of the airway sometimes resulting from long-term intubation). They are also used for pulmonary toilet and in the child who requires chronic mechanical ventilation. The tracheostomy facilitates secretion removal, reduces work of breathing, and increases client comfort. In some cases the tracheostomy facilitates mechanical ventilation weaning. It may be permanent or temporary, depending on the indication. The tracheostomy

FIGURE 39.17 The home apnea monitor uses a soft belt with a Velcro attachment to hold two leads in the appropriate position on the chest.

tube varies in size and type depending on the child's airway size and health and the length of time the child will require the tracheostomy. Silastic tracheostomy tubes are soft and flexible; they are available with a single lumen or may have an outer and inner lumen. Both types have an obturator (the guide used during tube changes). Typically, the tubes with inner cannulas are used with older children and in children with increased mucus production. Cuffed tracheostomy tubes are generally used in older children also. The cuff is used to prevent air from leaking around the tube. The funnel-shaped airway in younger children acts a physiological cuff and prevents air leakage. Figure 39.18 shows various types of tracheostomy tubes.

Complications immediately after surgery include hemorrhage, air entry, pulmonary edema, anatomic damage, and respiratory arrest. At any point in time the tracheostomy tube may become occluded and ventilation compromised. Complications of chronic tracheostomy include infection, cellulitis, and formation of granulation tissue around the insertion site (Russell, 2005).

Nursing Assessment

When obtaining the history for a child with a tracheostomy, note the reason for the tracheostomy, as well as the size and type of tracheostomy tube. Inspect the site. The stoma should appear pink and without bleeding or drainage. The tube itself should be clean and free from secretions. The tracheostomy ties should fit securely, allowing one finger to slide beneath the ties (Fig. 39.19). Inspect the skin under the ties for rash or redness. Observe work of breathing.

When caring for the infant or child with a tracheostomy, whether in the intensive care unit, the ward, or the home, a thorough respiratory assessment is necessary. Note presence of secretions and their color, thickness, and amount. Auscultate for breath sounds, which should be clear and equal throughout all lung fields. Pulse oximetry may also be measured. When infection is suspected or secretions are discolored or have a foul odor, a sputum culture may be obtained.

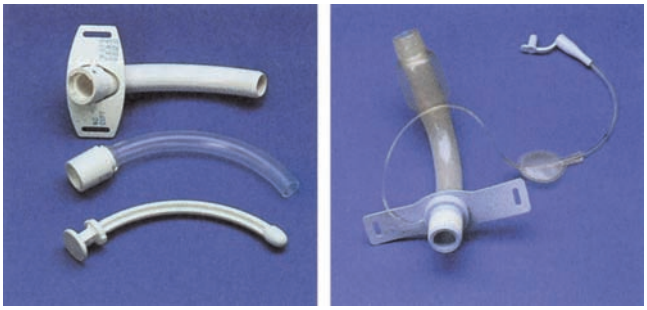


FIGURE 39.18 Note smaller size and absence of inner cannula on particular brands of pediatric tracheostomy tubes.

FIGURE 39.19 Properly fitting trach ties. One fingerwidth fits between the ties and the child's neck.

▶ ***Take*** *NOTE!*

Keep small toys (risk of aspiration), plastic bibs or bedding (risk of airway occlusion), and talcum powder (risk of inhalation injury) out of reach of the child with a tracheostomy.

Nursing Management

In the immediate postoperative period the infant or child may require restraints to avoid accidental dislodgment of the tracheostomy tube. Infants and children who have had a tracheostomy for a period of time become accustomed to it and usually do not attempt to remove the tube. Since air inspired via the tracheostomy tube bypasses the upper airway, it lacks humidification, and this lack of humidity can lead to a mucus plug in the tracheostomy and hypoxia. Provide humidity to either room air or oxygen via a tracheostomy collar or ventilator, depending on the child's need (Fig. 39.20). Box 39.4 lists the equipment that should be available at the bedside of any child who has a tracheostomy.

Tracheostomies require frequent suctioning to maintain patency. The appropriate length for insertion of the suction catheter depends on the size of the tracheostomy and the child's needs. Place a sign at the head of the child's bed indicating the suction catheter size and the length (in centimeters) that it should be inserted for suctioning. Keep

FIGURE 39.20 The trach collar allows for humidification of inspired air or supplemental oxygen.

an extra tracheostomy tube of the same size and one size smaller at the bedside in the event of an emergency.

Many pediatric tracheostomy tubes do not have an inner cannula that requires periodic removal and cleaning, so periodic removal and replacement of the chronic tracheostomy tube is required. Clean the removed tracheostomy tube with half-strength hydrogen peroxide and pipe cleaners. Rinse with distilled water and allow it to dry. The tracheostomy tube can be reused many times if adequately cleaned between uses.

Perform tracheostomy care every 8 hours or per institution protocol. Change the tracheostomy tube only as needed or per institution protocol. Nursing Procedure 39.3 gives information about tracheostomy care.

If the older child or teen has a tracheostomy tube with an inner cannula, care of the inner cannula is similar to that of an adult. Involve parents in care of the tracheostomy and begin education about caring for the tracheostomy tube at home as soon as the child is stable. Refer the family to local support groups or to www.tracheostomy.com, which offers many resources for a family whose child has a tracheostomy. The child with a tracheostomy often qualifies for a Medicaid waiver that will provide a certain amount of home nursing care.

Always change tracheostomy ties with an assistant to avoid accidental dislodgement of the tube.

Nursing Procedure 39.3

Tracheostomy Care

1. Gather the necessary equipment:
   - Cleaning solution
   - Gloves
   - Precut gauze pad
   - Cotton-tipped applicators
   - Clean tracheostomy ties
   - Scissors
   - Extra tracheostomy tube in case of accidental dislodgement
2. Position the infant/child supine with a blanket or towel roll to extend the neck.
3. Open all packaging and cut tracheostomy ties to appropriate length if necessary.
4. Cleanse around the tracheostomy site with prescribed solution (half-strength hydrogen peroxide or acetic acid, normal saline or soap and water if at home) and cotton-tipped applicators, working from just around the tracheostomy tube outward.
5. Rinse with sterile water and cotton-tipped applicator in similar fashion.
6. Place the precut sterile gauze under the tracheostomy tube.
7. With the assistant holding the tube in place, cut the ties and remove from the tube.
8. Attach the clean ties to the tube and tie or secure in place with Velcro.

BOX 39.4 Emergency Equipment (Available at Bedside)

- Two spare tracheostomy tubes (one the same size and one a size smaller)
- Suction equipment
- Stitch cutter (new tracheostomy)
- Spare tracheostomy ties
- Lubricating jelly
- Bag-valve-mask device
- Call bell within child's/parent's reach

Key Concepts

- Respiratory infections account for the majority of acute illnesses in children.
- The upper and lower airways are smaller in children than adults, making them more susceptible to obstruction in the presence of mucus, debris, or edema.
- Newborns are obligatory nose breathers.
- The child's highly compliant airway is quite susceptible to dynamic collapse in the presence of airway obstruction.
- Because they have fewer alveoli, children have a higher risk for hypoxemia than adults.
- Generally, disorders of the nose and throat do not result in increased work of breathing or affect the lungs. Thus, if the lungs are involved, lower respiratory disease must be considered.

- Wheezing may be associated with a variety of lower respiratory disorders, such as asthma, bronchiolitis, and cystic fibrosis.
- Pulse oximetry is a useful tool for determining the extent of hypoxia. Findings should be correlated with the child's clinical presentation.
- Rapid streptococcus and rapid flu tests are very useful for the quick diagnosis of strep throat or influenza so that appropriate treatment may be instituted early in the illness.
- Supplemental oxygen is often necessary in the child who is hospitalized (particularly with lower respiratory disease). Oxygen should be humidified to prevent drying of secretions.
- Suctioning, whether with a bulb syringe or suction catheter, is very effective at maintaining airway patency, especially in the younger child or infant.
- Normal saline nasal wash is an inexpensive, simple, and safe method for decongesting the nose in the case of the common cold, allergic rhinitis, and sinusitis.
- Infants who were born prematurely, children with a chronic illness such as diabetes, congenital heart disease, sickle cell anemia, or cystic fibrosis, and children with developmental disorders such as cerebral palsy tend to be more severely affected with respiratory disorders.
- Passive cigarette smoke exposure increases the infant's and child's risk for respiratory disease.
- Continual swallowing while awake or asleep is an indication of bleeding in the postoperative tonsillectomy patient.
- Positioning to ease work of breathing and maintaining a patent airway are priorities for the child with a respiratory disorder.
- To avoid Reye syndrome, aspirin should not be given to treat fever or pain in the infant or child with a viral infection.
- Infants and children at high risk for serious RSV disease should be immunized with Synagis each RSV season. Children 6 to 23 months of age should be immunized against influenza yearly.
- Children at high risk for exposure to tuberculosis should be screened for infection.
- Promoting airway clearance and maintenance, effective breathing patterns, and adequate gas exchange is the priority focus of nursing intervention in pediatric respiratory disease.
- Children with any degree of respiratory distress require frequent assessment and early intervention to prevent progression to respiratory failure.
- Avoidance of allergens is critical in the treatment plan for the child with allergic rhinitis.
- Avoidance of allergic triggers, control of the inflammatory process, and education of the child and family are the focus of asthma management.
- Chest physiotherapy is extremely useful for mobilizing secretions in any condition resulting in an increase in mucus production and is required in children with cystic fibrosis.
- Children with chronic respiratory disorders and their families often need large amounts of education and psychosocial support: children often experience fear and isolation, while families must learn to balance care of the chronically ill child with other family life.

Chapter Worksheet

Multiple Choice Questions

1. A 5-month-old infant with RSV bronchiolitis is in respiratory distress. The baby has copious secretions, increased work of breathing, cyanosis, and a respiratory rate of 78. What is the most appropriate initial nursing intervention?
   a. Attempt to calm the infant by placing him in his mother's lap and offering him a bottle.
   b. Alert the physician to the situation and ask for an order for a stat chest x-ray.
   c. Suction secretions, provide 100% oxygen via mask, and anticipate respiratory failure.
   d. Bring the emergency equipment to the room and begin bag-valve-mask ventilation.
2. A toddler has moderate respiratory distress, is mildly cyanotic, and has increased work of breathing, with a respiratory rate of 40. What is the priority nursing intervention?
   a. Airway maintenance and 100% oxygen by mask
   b. 100% oxygen and pulse oximetry monitoring
   c. Airway maintenance and continued reassessment
   d. 100% oxygen and provision of comfort
3. The nurse is caring for a child with cystic fibrosis who receives pancreatic enzymes. Which statement by the child's mother indicates an understanding of how to administer the supplemental enzymes?
   a. "I will stop the enzymes if my child is receiving antibiotics."
   b. "I will decrease the dose by half if my child is having frequent, bulky stools."
   c. "Between meals is the best time for me to give the enzymes."
   d. "The enzymes should be given at the beginning of each meal and snack."
4. Which of these factors contributes to infants' and children's increased risk for upper airway obstruction as compared with adults?
   a. Underdeveloped cricoid cartilage and narrow nasal passages
   b. Small tonsils and narrow nasal passages
   c. Cylinder-shaped larynx and underdeveloped sinuses
   d. Underdeveloped cricoid cartilage and smaller tongue
5. Which is the most appropriate treatment for epistaxis?
   a. With the child lying down and breathing through the mouth, apply pressure to the bridge of the nose.
   b. With the child lying down and breathing through the mouth, pinch the lower third of the nose closed.
   c. With the child sitting up and leaning forward, apply pressure to the bridge of the nose.
   d. With the child sitting up and leaning forward, pinch the lower third of the nose closed.

Critical Thinking Exercises

1. A 10-month-old girl is admitted to the pediatric unit with a history of recurrent pneumonia and failure to thrive. Her sweat chloride test confirms the diagnosis of cystic fibrosis. She is a frail-appearing infant with thin extremities and a slightly protuberant abdomen. She is tachypneic, has retractions, and coughs frequently. Based on the limited information given here and your knowledge of cystic fibrosis, choose three of the categories below as priorities to focus on when planning her care:
   a. Prevention of bronchospasm
   b. Promotion of adequate nutrition
   c. Education of the child and family
   d. Prevention of pulmonary infection
   e. Balancing fluid and electrolytes
   f. Management of excess weight gain
   g. Prevention of spread of infection
   h. Promoting adequate sleep and rest
2. A boy with asthma is admitted to the pediatric unit for the fourth time this year. The mother expresses frustration that he is getting sick so often. Besides information about onset of symptoms and events leading up to this present episode, what other types of information would you ask for while obtaining the history?
3. The mother of the boy in the previous question tells you that she smokes (but never around the boy), the family has a cat that comes inside sometimes, and she always gives her son the medication prescribed. She gives salmeterol and budesonide as

soon as he starts to cough. When he is not having an episode, she gives him albuterol before his baseball games. Diphenhydramine helps his runny nose in the springtime. Based on this new information, what advice/instructions would you give the mother?

4. A 7-year-old presents with a history of recurrent nasal discharge. He sneezes every time he visits his cousins, who have pets. He lives in an older home that is carpeted. Tobacco smokers live in the home. His mother reports that he snores and is a mouth breather. She says he has symptoms nearly year-round, but they are worse in the fall and the spring. She reports that diphenhydramine is somewhat helpful with his symptoms, but she doesn't like to give it to him on school days because it makes him drowsy. Based on the history above, develop a teaching plan for this child.

5. The nurse is caring for a 4-year-old girl who returned from the recovery room after a tonsillectomy 3 hours ago. She has cried off and on over the past 2 hours and is now sleeping. What areas should the nurse assess and focus on for this patient?

Study Activities

1. While caring for children in the pediatric setting, compare the signs and symptoms of a child with asthma to those of an infant with bronchiolitis. What are the most notable differences? How does the history of the two children differ?

2. A child with asthma has been prescribed Advair (fluticasone and salmeterol), albuterol, and prednisone. Develop a sample teaching plan for the child and family. Include appropriate use of the devices used to deliver the medications, as well as important information about the medications (uses and adverse effects).

3. While caring for children in the pediatric setting, compare the signs and symptoms and presentation of a child with the common cold to those of a child with either sinusitis or allergic rhinitis.

4. While caring for children in the pediatric setting, review the census of clients and identify those at risk for severe influenza and thus those who would benefit from annual influenza vaccination.

5. Compare the differences in oxygen administration between a young infant and an older child.

CHAPTER 40

Nursing Care of the Child with a Cardiovascular Disorder

Logan Bernstein, 6 weeks old, is brought to the clinic by his mother. He presents with poor feeding. His mother states, "Logan falls asleep while feeding, and he's always very sweaty during feedings."

KEY TERMS

arrhythmia
cardiac monitoring
cardiac output
cardiomegaly
clubbing
congenital heart defect
echocardiography
electrocardiogram (ECG, EKG)
heart failure
orthotopic
polycythemia
sinus bradycardia
sinus tachycardia
tetralogy of Fallot

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Compare anatomic and physiologic differences of the cardiovascular system in infants and children versus adults.
2. Describe nursing care related to common laboratory and diagnostic tests used in the medical diagnosis of pediatric cardiovascular conditions.
3. Distinguish cardiovascular disorders common in infants, children, and adolescents.
4. Identify appropriate nursing assessments and interventions related to medications and treatments for pediatric cardiovascular disorders.
5. Develop an individualized nursing care plan for the child with a cardiovascular disorder.
6. Describe the psychosocial impact of chronic cardiovascular disorders on children.
7. Devise a nutrition plan for the child with cardiovascular disease.
8. Develop patient/family teaching plans for the child with a cardiovascular disorder.

Wow

The heart of the matter is healing the child's heart so he or she can embrace life to its fullest.

Cardiovascular disease is a significant cause of chronic illness and death in children. Typically cardiovascular disorders in children are divided into two major categories: congenital heart disease (CHD) and acquired heart disease. Congenital heart disease is defined as structural anomalies that are present at birth, though they are often not diagnosed until later in life. CHD accounts for the largest percentage of birth defects, and about 40,000 babies are born annually with a **congenital heart defect** (American Heart Association [AHA], 2008c). Acquired heart disease includes disorders that occur after birth. These disorders develop from a wide range of causes, or they can occur as a complication or long-term effect of CHD. Over 100 genes have been identified that may be involved in the development of CHD (Cunningham et al., 2005). Additional noncardiac anomalies occur in about 28% of children with CHD. CHD is also commonly associated with chromosomal abnormalities and occurs at a rate of about 3% in children with first-degree relatives who have CHD (Fixler, 2006). Many congenital heart defects result in heart failure and chronic cyanosis, leading to failure to thrive.

The diagnosis of a cardiovascular disorder in any person can be extremely frightening and overwhelming. This is even truer for the child and his or her parents. Early on, children learn that the heart is necessary for life, so knowing that there is a heart problem can promote feelings of dread. These feelings are compounded by the child's age, the view of the child as being vulnerable and defenseless, and the stressors associated with the disorder itself. The child and parents need much support and reassurance.

Nurses need to have a sound knowledge base about cardiovascular conditions affecting children so that they can provide appropriate assessment, intervention, guidance, and support to the child and family. Cardiovascular disorders require acute interventions that often have long-term implications for the child's health and growth and development. Due to the potentially overwhelming and devastating effects that cardiovascular disorders can have on children and their families, nurses need to be skilled in assessment and interventions in this area and able to provide support throughout the course of the illness and beyond. This chapter describes the nursing management of children with congenital and acquired cardiovascular disorders, highlighting the common procedures used for treatment.

Variations in Pediatric Anatomy and Physiology

The cardiovascular system undergoes numerous changes at birth. Structures that were vital to the fetus are no longer needed. Circulation via the umbilical arteries and vein is replaced with the child's own closed independent circulation. Changes in the size of the heart, pulse rate, and blood pressure also occur.

Circulatory Changes From Gestation to Birth

The fetal heart is developed within the first 21 days of gestation, with the development of the heart rate and fetal blood circulation. The four chambers of the heart and arteries are formed during gestational months 2 through 8. During fetal development, oxygenation of the fetus occurs via the placenta; the lungs, though perfused, do not perform oxygenation and ventilation. The foramen ovale, an opening between the atria, allows blood flow from the right to the left atrium. The ductus arteriosus allows blood flow between the pulmonary artery and the aorta, shunting blood away from the pulmonary circulation (Molczan, 2006; Valente et al., 2006). Figure 40.1 illustrates fetal circulation.

With the first breath, several changes occur in the cardiopulmonary system that enable the newborn to make the transition from fetal circulation to normal circulation. As the newborn breathes for the first time, the lungs inflate, reducing pulmonary vascular resistance to blood flow. As a result, pulmonary artery pressure drops. Subsequently, pressure in the right atrium decreases. Blood flow to the left side of the heart increases the pressure in the left atrium. This change in pressure leads to closure of the foramen ovale. The drop in pressure of the pulmonary artery promotes closure of the ductus arteriosus, which is located between the aorta and pulmonary artery. The ductus venosus, located between the left umbilical vein and the inferior vena cava, closes because of a lack of blood flow and vasoconstriction. The closed ductus arteriosus and ductus venosus eventually become ligaments. With the lack of blood flow to the umbilical arteries and vein, these structures atrophy.

Structural and Functional Differences

The structure and function of the infant's and child's cardiovascular system differ from those of adults, depending on age. In infants and children under 7, the heart lies more horizontally. As a result, the apex lies higher, below the fourth intercostal space. In the infant, the heart lies higher in the chest and occupies over half of the chest width. As the lungs grow over time, the heart is displaced downward. The toddler/preschooler (between 1 and 6 years) has a heart four times the birth size. By school age (between 6 and 12 years) the child's heart is 10 times the size it was at birth. However, the heart is smaller proportionally at this time than at any other stage in life. During the school-age years, the heart grows more vertically within the thoracic cavity. During adolescence, the heart continues to grow in relation to the teen's rapid growth.

At birth, the ventricle walls are similar in thickness, but with time the left ventricular wall thickens. The immature myocytes of the infant's heart are thinner and less compliant than those of the adult. Right ventricular function dominates at birth, and over the first few months of life, left

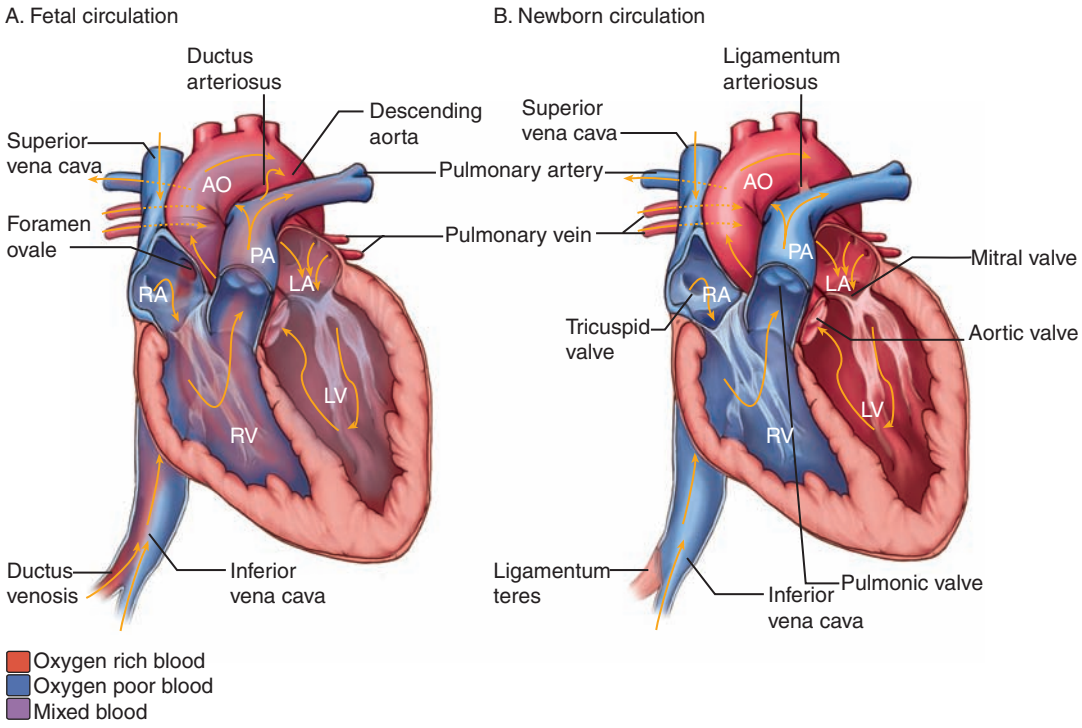

FIGURE 40.1 Fetal and newborn circulation.

ventricular function becomes dominant. The infant's heart at rest exhibits a greater resting tension than the adult's, so volume loading or increased stretch may actually lead to decreased **cardiac output**. The infant's sarcoplasmic reticulum is less well organized than the adult's, making the infant dependent on serum calcium for contraction. Inotropic response to calcium in the actin and myosin (contractile proteins) increases with age.

The normal heart rate is higher in infancy than in adulthood, limiting the infant's ability to increase cardiac output by increasing the heart rate. The heart's efficiency increases as the child ages and the heart rate drops over time. The normal infant heart rate averages 120 to 130 beats per minute (bpm), the toddler's or preschooler's is 80 to 105 bpm, the school-age child's is 70 to 80 bpm, and the adolescent's averages 60 to 68 bpm. Innocent murmurs and physiologic splitting of heart sounds may be noted in infancy or childhood. These findings are related to the change in the size of the heart in relation to the thoracic cavity. The infant's and child's blood vessels widen and increase in length over time. The normal infant's blood pressure (BP) is about 80/40 mm Hg. The BP increases over time to the adult level. The toddler or preschooler's BP averages 80 to 100/64 mm Hg, the school-age child's 94 to 112/56 to 60 mm Hg, and the adolescent's 100 to 120/50 to 70 mm Hg (Frietas-Nichols, 2004; Luxner, 2005; Muscari, 2004).

Common Medical Treatments

A variety of medications as well as other medical treatments and surgical procedures are used to treat cardiovascular problems in children. Most of these treatments will require a physician's order when the child is in the hospital. The most common treatments and medications are listed in Common Medical Treatments 40.1 and Drug Guide 40.1. The nurse caring for the child with a cardiovascular disorder should be familiar with what the procedures and medications are and how they work as well as common nursing implications related to use of these modalities.

▶ ***Take*** NOTE!

Give digoxin at regular intervals, every 12 hours, such as at 8 a.m. and 8 p.m., 1 hour before or 2 hours after a feeding. If a digoxin dose is missed and more than 4 hours have elapsed, withhold the dose and give the dose at the regular time; if less than 4 hours have elapsed, give the missed dose. If the child vomits digoxin, ***do not*** *give a second dose. Monitor potassium levels, as a decrease enhances the effects of digitalis, causing toxicity.*

NURSING PROCESS OVERVIEW FOR THE CHILD WITH A CARDIOVASCULAR DISORDER

Care of the child with a cardiovascular disorder includes all of the typical steps of the nursing process: assessment, nursing diagnosis, planning, interventions, and evaluation.

(text continues on page 1285)

COMMON MEDICAL TREATMENTS 40.1

Treatment	Explanation	Indication	Nursing Implications
Oxygen	Supplemented via mask, nasal cannula, hood, tent or via endotracheal/nasotracheal tube	Hypoxemia, respiratory distress, heart failure	Monitor response via work of breathing and pulse oximetry.
Chest physiotherapy (CPT) and postural drainage	Promotes mucus clearance by mobilizing secretions with the assistance of percussion or vibration accompanied by postural drainage (refer to Chapter 39 for additional information related to CPT and postural drainage)	Mobilization of secretions, particularly in postoperative period or with heart failure	May be performed by respiratory therapist in some institutions, by nurses in others. In either case, nurses must be familiar with the technique and able to educate families on its use.
Chest tube	Drainage tube is inserted into the pleural cavity to facilitate removal of air or fluid and allow full lung expansion.	After open heart surgery, pneumothorax	If tube becomes dislodged from container, the chest tube must be clamped immediately to avoid further air entry into the chest cavity.
Pacing	External wiring connected to a small generator used to electrophysiologically correct cardiac arrhythmias or heart block (temporary). Permanent pacing achieved with an implantable internal pacemaker.	Bradyarrhythmias, heart block, cardiomyopathy, sinoatrial or atrioventricular node malfunction	Provide close observation of the child, pacing unit, and ECG. Maintain asepsis at pacing lead insertion site. Explain to child and family that the permanent pacemaker may be felt under the skin. Advise against participation in contact sports.

DRUG GUIDE 40.1

Medication	Action/Indication	Nursing Implications
Alprostadil (Prostin VR: prostaglandin E_1)	Direct vasodilation of the ductus arteriosus smooth muscle. Indicated for temporary maintenance of ductus arteriosus patency in infants with ductal-dependent congenital heart defects.	• Apnea occurs in 10% to 20% of neonates within first hour of infusion. • Monitor arterial BP, respiratory rate, heart rate, ECG, temperature, pO_2; watch for abdominal distention. • Fresh IV solution required every 24 hours. • Reposition catheter if facial or arm flushing occurs. • Use with caution in neonate with bleeding tendency. • Contraindicated in respiratory distress syndrome or persistent fetal circulation.
Digoxin (Lanoxin)	Increases contractility of the heart muscle by decreasing conduction and increasing force. Used for heart failure, atrial fibrillation, atrial flutter, supraventricular tachycardia.	• Prior to administering each dose, count apical pulse for 1 full minute, noting rate, rhythm, and quality. Withhold if apical pulse is <60 in an adolescent, <90 in an infant. • Avoid giving oral form with meals, as altered absorption may occur. • Monitor serum digoxin levels (therapeutic range: 0.8–2 ng/mL). • Notes signs of toxicity: nausea, vomiting, diarrhea, lethargy, bradycardia. • Ginseng, hawthorn, and licorice intake increases risk for drug toxicity.

(continued)

DRUG GUIDE 40.1 (continued)

Medication	Action/Indication	Nursing Implications
		• Note contraindications (ventricular fibrillation and hypersensitivity to digitalis). • Avoid rapid IV administration, as this may lead to systemic and coronary artery vasoconstriction.
Furosemide (Lasix)	Inhibits resorption of sodium and chloride. Used to manage edema associated with heart failure, and hypertension in combination with antihypertensives.	• Administer with food or milk to decrease GI upset. • Monitor BP, renal function, electrolytes (particularly potassium), and hearing. • May cause photosensitivity.
Heparin	Interferes with conversion of prothrombin to thrombin, preventing clot formation. Indicated for the prophylaxis and treatment of thromboembolic disorders, especially after cardiac surgery.	• Administer SQ, not IM. • Dose is adjusted according to coagulation test results. • Monitor for signs of bleeding, platelet counts. • Ensure that the antidote, protamine sulfate, is available. • Do not administer with uncontrolled bleeding or if subacute bacterial endocarditis is suspected.
Indomethacin (Indocin)	Inhibits prostaglandin synthesis in order to close patent ductus arteriosus.	• Monitor heart rate, BP, ECG, urine output; monitor for murmur. • Monitor serum sodium, glucose, platelet count, BUN, creatinine, potassium, and liver enzymes. • May mask signs of infection. • Note development of edema.
Spironolactone (Aldactone)	Competes with aldosterone to result in increased water and sodium excretion (spares potassium). Used to manage edema due to heart failure and for treatment of hypertension.	• Administer with food. • Monitor serum potassium, sodium, and renal function. • May cause drowsiness, headache, arrhythmia. • May cause false elevations in digitalis level. • Teach patients to avoid high-potassium diets, salt substitutes, and natural licorice. • Contraindicated in hyperkalemia, renal failure, and anuria.
Antibiotics		
Penicillin G benzathine (PCN-G) Penicillin V potassium (Pen-VK)	Inhibits bacterial wall synthesis in susceptible organisms. Indicated in mild to moderate infections, for prophylaxis of endocarditis and rheumatic fever.	• Contraindications include hypersensitivity to penicillins. • Report hypersensitivity reactions (chills, fever, wheezing, pruritus, anaphylaxis) immediately. • PCN-G: administer IM. • Pen-VK: administer orally on empty stomach 1 hour prior to or 2 hours after a meal.
Erythromycin	Inhibits RNA transcription in susceptible organisms. Used in children with penicillin allergy, mild to moderate infections, endocarditis, and for rheumatic fever prophylaxis.	• Contraindicated in preexisting liver disease. • IV administration may result in CV abnormalities. • Abdominal distress common with oral use. • Fever, dizziness, rash may occur.
Antihypertensive Drugs		
Angiotensin-converting enzyme (ACE) inhibitors (captopril [Capoten], enalapril [Vasotec])	Competitive inhibition of ACE for management of hypertension. Heart failure management in conjunction with digitalis and diuretics.	• Monitor BP, renal function, WBC count, serum potassium. • Discontinue if angioedema occurs. • Captopril: administer orally on empty stomach 1 hour before or 2 hours after meals. • Enalapril: may administer orally without regard to food.

Medication	Action/Indication	Nursing Implications
Beta-adrenergic blockers (propranolol [Inderal], atenolol [Tenormin], sotalol [Betapace])	Competitively blocks response to beta-adrenergic stimulation decreasing heart rate and force of contraction. Used for management of hypertension, arrhythmias, and prevention of myocardial infarction.	• Monitor ECG and BP. • Propranolol: administer with food. • Atenolol, sotalol: administer without regard to food. Do not stop drug abruptly. • May result in bradycardia, dizziness, nausea and vomiting, dyspnea, hypoglycemia (propranolol). • Contraindications: heart block, uncompensated heart failure, cardiogenic shock, asthma, or hypersensitivity.
Hydralazine (Apresoline)	Direct vasodilation of arterioles to manage moderate to severe hypertension, heart failure.	• Monitor heart rate, BP. • Closely monitor BP with IV use. • Administer oral dose with food. • May cause palpitations, flushing, tachycardia, dizziness, nausea and vomiting. • Notify physician if flu-like symptoms occur. • Contraindicated in rheumatic valvular disease.

There are a number of general concepts related to the nursing process that may be applied to any child with a cardiovascular disorder. The nurse should be knowledgeable about the procedures, treatments, and medication as well as familiar with the nursing implications related to these interventions. With an understanding of these concepts, the nurse can individualize the care based on the patient's and family's needs.

Remember Logan, the 6-week-old with poor feeding? What additional health history and physical examination assessment information should the nurse obtain?

Assessment

When assessing a child with a cardiovascular disorder, expect to obtain a health history, perform a physical examination, and prepare the child for laboratory and diagnostic testing.

Health History

The health history comprises a history of the present illness, past medical history, and family history. Depending on his or her age, the child should be included in the health history interview; the child's age will determine the degree of involvement and the terminology used. Table 40.1 gives examples of typical questions that can be used when obtaining the child's health history.

History of Present Illness

Elicit the history of the present illness, which addresses when the symptoms started and how they have progressed. Inquire about any treatments and medications used at home. Ask parents about history of orthopnea, dyspnea, easy fatigability, growth delays, squatting, edema, dizziness, and/or frequent occurrences of pneumonia, which can be significant signs of pediatric heart disease (Muscari, 2004). The history of present illness may reveal a history of poor feeding, including fatigue, lethargy, and/or vomiting, or failure to thrive, even with adequate caloric intake. The parents may report diaphoresis, which is often seen in early heart failure. Delays in gross motor development, cyanosis (possibly reported by the parents as more of a gray color than blue), and tachypnea (indicative of heart failure) may also be reported by the parent or caregiver.

Past Medical History

The past medical history includes information about the child as well as the mother's pregnancy history. Assess the child's past medical history for:

- Problems occurring after birth (history of the child's condition after birth may reveal evidence of an associated congenital malformation or other disorder)
- Frequent infections
- Chromosomal abnormalities
- Prematurity
- Autoimmune disorders
- Use of medications, such as corticosteroids

Assess the mother's pregnancy, labor, and delivery history. Be sure to include information about the status of the neonate at birth. Also inquire about maternal use of medications, including illicit or over-the-counter drugs and alcohol; exposure to radiation; presence of hypertension; and maternal viral illnesses such as coxsackievirus, cytomegalovirus, influenza, mumps, or rubella. A history of significant problems related to labor and delivery

TABLE 40.1 Examples of Questions for Obtaining a Child's Health History

Questions	Provides Information About:
• What types and amounts (dosages) of medications has the child received? What were they used for? • Who prescribed them? • Were they effective? Did the child experience any adverse effects?	• Possible underlying conditions that may be related to the child's current status • Other health care personnel involved in the child's care as well as the parents' health care beliefs and patterns • How the medications may be affecting the child's health
• To whom does the child go for medical evaluation? How often? Were the visits for regular health check-ups or for situational problems? Were there previous hospitalizations? What for?	• The child's health status and the parents' health care knowledge, practices, and beliefs
• Has the child experienced any growth delay? Does the child have any problems with activity and coordination?	• Problems that may result from impaired cardiac output, adequacy of tissue oxygenation, and concomitant disorders associated with heart disease
• Does the child's skin color change when crying? If so, what color do you see?	• Effectiveness of tissue oxygenation. A blue or gray skin color may be due to cyanosis.
• Does the child stop frequently during play to sit or squat?	• The child's exercise tolerance and tissue oxygenation
• Does the child have feeding difficulty? Does the child tire easily or sleep excessively?	• The child's energy expenditure, ability to tolerate activity, and tissue oxygenation
• Does the child frequently develop strep throat?	• Child's risk for developing rheumatic fever and heart disease

is also important: stress or asphyxia at birth may be related to cardiac dysfunction and pulmonary hypertension in the newborn.

Assess for additional risk factors such as:

- Family history of heart disease or CHD (investigate the history further if heart disease occurred in a first-degree relative)
- Hyperlipidemia
- Diabetes mellitus
- Obesity
- Inactivity
- Stress
- High-cholesterol diet (Freitas-Nichols, 2004; Muscari, 2004)

▶ **Take** NOTE!

Medications taken by pregnant women such as isotretinoin (Accutane) for acne, lithium, and some antiseizure medications may be linked to the development of congenital heart defects. In addition, smoking during pregnancy, febrile illness in the first trimester, rubella infection during pregnancy, exposure of the pregnant woman to strong cleaning products, repeated x-rays, and any harmful or poisonous material can increase the risk of CHD.

Physical Examination

Physical examination of the child with a cardiovascular condition consists of inspection, palpation, and auscultation. In addition, obtain the child's vital signs and measure the child's height and weight. Plot this information on a standard growth chart to evaluate nutritional status and growth. If the child is less than 3 years of age, measure and plot the head circumference also.

Inspection

Assess the child's overall appearance. Inspect the color of the skin, noting cyanosis. Inspect the skin for edema. In infants, peripheral edema occurs first in the face, then the presacral region, and then the extremities. Edema of the lower extremities is characteristic of right ventricular heart failure in older children.

▶ **Take** NOTE!

CHD should be suspected in the cyanotic newborn who does not improve with oxygen administration.

Inspect the fingers and toes for **clubbing**. Clubbing (which usually does not appear until after 1 year of age) implies chronic hypoxia due to severe congenital heart disease. The first sign of clubbing is softening of the nail

beds, followed by rounding of the fingernails, followed by shininess and thickening of the nail ends (see Fig. 39.6 in Chapter 39).

Obtain the child's temperature; fever would suggest infection. Assess respirations, including rate, rhythm, and effort. Note location and severity of retractions if present. Inspect the chest configuration, noting any prominence of the precordial chest wall, which is often seen in infants and children with **cardiomegaly**. Note visible pulsations, which may indicate increased heart activity. Also inspect the neck veins for engorgement or abnormal pulsations. Note abdominal distention (Frietas-Nichols, 2004; Muscari, 2004; Valente et al., 2006).

▶ *Take* NOTE!

Children with cardiac conditions resulting in cyanosis will often have baseline oxygen saturations that are relatively low because of the mixing of oxygenated with deoxygenated blood.

Palpation

Palpate the right and left radial or brachial pulse to assess cardiac rate and rhythm. Throughout infancy and childhood, the rate may vary. Palpate the femoral pulse; it should be readily palpable and equal in amplitude and strength to the brachial or radial pulse. A femoral pulse that is weak or absent in comparison to the brachial pulse is associated with coarctation of the aorta. Significant variations in pulse occur with activity, so the most accurate heart rate may be determined during sleep. In older children, exercise and emotional factors may influence the heart rate. A bounding pulse is characteristic of patent ductus arteriosus or aortic regurgitation. Narrow or thready pulses may occur in children with heart failure or severe aortic stenosis. Note **tachycardia**, **bradycardia**, irregularities in rhythm, diminished peripheral pulses, or thready pulse. Palpate the child's abdomen for hepatomegaly, a sign of right-sided heart failure in the infant and child.

Auscultation

Auscultate the apical pulse for a full minute to determine heart rate and rhythm. Note irregularities in rhythm, tachycardia or bradycardia. Auscultate the heart for murmurs. Many children have functional or innocent murmurs, but all murmurs must be evaluated on the basis of the following characteristics:

- Location
- Relation to the heart cycle and duration
- Intensity: grade I, soft and hard to hear; grade II, soft and easily heard; grade III, loud without thrill; grade IV, loud with a precordial thrill; grade V, loud, audible with a precordial thrill; grade V, loud, audible with a stethoscope; grade VI, very loud, and audible with a stethoscope or with the naked ear
- Quality: harsh, musical, or rough; high, medium, or low pitch
- Variation with position (sitting, lying, standing) (Freitas-Nichols, 2004; Muscari, 2004; Valente et al., 2006)

Auscultate for the character of heart sounds. Note distinct, muffled, or distant heart sounds. Abnormal splitting or intensifying of S2 sounds occurs in children with major heart problems. Ejection clicks, which are high-pitched, are related to problems with dilated vessels and/or valve abnormalities. Heard throughout systole, they can be early, moderate, or late. Clicks on the upper left sternal border are related to the pulmonary area. Aortic clicks are best heard at the apex and can be mitral or aortic in origin. A mild to late ejection click at the apex is typical of a mitral valve prolapse. The S3 heart sound may be heard in children and is associated with cardiac abnormalities. The S4 heart sound is not normally heard and is always associated with cardiac abnormalities (Driscoll, 2006; Muscari, 2004).

Auscultate the BP in the upper extremities and lower extremities and compare the findings; there should be no major differences between the upper and lower extremities. Determine the pulse pressure by subtracting the diastolic pressure from the systolic pressure. The pulse pressure is less than 50 Hg, or less than half the systolic pressure. A widened pulse pressure, which usually is accompanied by a bounding pulse, is associated with patent ductus arteriosus, aortic insufficiency, fever, anemia, or complete heart block. A narrowed pulse pressure is associated with aortic stenosis. Note hypotension or hypertension.

▶ *Take* NOTE!

Children and parents must be alerted if a heart murmur is detected, even if it is benign.

Laboratory and Diagnostic Testing

Common Laboratory and Diagnostic Tests 40.1 explains the laboratory and diagnostic tests most commonly used when considering cardiovascular disorders in children. The tests can assist the physician in diagnosing the disorder or can be used as guidelines in determining ongoing treatment. Laboratory or non-nursing personnel obtain some of the tests, while the nurse might obtain others. In either instance the nurse should be familiar with how the tests are obtained, what they are used for, and normal versus abnormal results. This knowledge will also be

COMMON LABORATORY AND DIAGNOSTIC TESTS 40.1

Test	Explanation	Indications	Nursing Implications
Arteriogram (angiogram: visualization of arteries or veins)	Radiopaque contrast solution is injected through a catheter and into the circulation. X-rays are then taken to visualize the structure of the heart and blood vessels.	To observe blood flow to parts of body and detect lesions; to confirm a diagnosis. Catheters can be used to remove plaques.	• Make sure the parent signs a consent form. • Administer premedication as ordered. • Obtain child's weight to determine amount of dye needed. • Keep the child NPO before the procedure according to institutional protocol. • After the procedure, maintain the child on bed rest. • Observe the puncture site for bleeding. • Monitor vital signs frequently and check the pulse distal to the site.
Ambulatory electrocardiographic monitoring (Holter)	Monitoring of the heart's electrical patterns for 24 hours using a portable compact unit	To identify and quantify arrhythmias in a 24-hour period during normal daily activities	• Instruct the child and parent to push the "event button" whenever chest pain, syncope, or palpitations occur. • Normal daily activities should be carried out during the testing period. • Having the child wear a snug undershirt over the leads helps to keep them in place.
Chest x-ray	A radiographic film of the chest area; will determine size of the heart and its chambers and pulmonary blood flow	Serves as a baseline for comparison with films taken after surgery; used to identify abnormalities of the lungs, heart, and other structures in the chest	• Instruct patient not to wear jewelry or any metal around neck or on the hospital gown. • Explain to the child and family that no pain or discomfort should result. • If a portable x-ray at bedside is done, remove electrodes temporarily.
Echocardiogram	Noninvasive ultrasound procedure used to assess heart wall thickness, size of heart chambers, motion of valves and septa, and relationship of great vessels to other cardiac structures	Specific diagnosis of structural defects; determines hemodynamics and detects valvular defects	• Assure the child that the echo does not hurt. • Instruct the child about ECG lead placement and use of gel on the scope's wand during the procedure. • Encourage the child to lie still throughout the test.
Electrocardiogram (ECG, EKG)	A graphic record produced by an electrocardiograph (device used to record the electrical activity of the myocardium to detect transmission of the cardiac impulse through the conductive tissues of the muscle). Facilitates evaluation of the heart rate, rhythm, conduction, and musculature.	To detect heart rhythm and chamber overload; also serves as a baseline for measuring postoperative complications	• Assure the child that monitoring is a painless procedure. • Place electrodes in the appropriate location. • The child must lie still during the ECG recording period (usually about 5 minutes). • Wipe electrode paste or jelly off after procedure.

Test	Explanation	Indications	Nursing Implications
Exercise stress test	Monitoring of heart rate, blood pressure, ECG, and oxygen consumption at rest and during exercise	Quantifies exercise tolerance; can be used to provoke symptoms or arrhythmias	• Child should be NPO for 4 hours prior to test. • Obtain baseline ECG and vital signs. • Instruct child to verbalize symptoms during testing. • Usually takes about 45 minutes.
Hemoglobin (Hgb) and hematocrit (Hct)	Measures the total amount of hemoglobin in the blood and indirectly measures the red blood cell number and volume	To detect anemia or polycythemia (may occur with CHD resulting in cyanosis)	• False elevations occur with dehydration. • May be obtained quickly via capillary puncture. • Normal values vary with age.
Partial pressure of oxygen (pO_2)	Measures the amount of oxygen in the blood	To determine the presence and degree of hypoxia	• Most accurate result is with arterial specimen (venous and capillary specimens demonstrate lower levels). • Observe child for cyanosis. • Supplement with oxygen per protocol.

necessary when providing patient and family education related to the testing.

Cardiac Catheterization

Cardiac catheterization is the definitive study for infants and children with cardiac disease and thus deserves special attention in this section on assessment of cardiovascular disorders. Cardiac catheterization has become almost a routine diagnostic procedure and may be performed on an outpatient basis. However, it is highly invasive and not without risks, especially in sick infants and children. Indications for cardiac catheterization include:

- Cardiovascular disease causing cyanosis in infants: these infants need to be catheterized as soon as they are in a reasonably stable condition
- Severe heart failure or progressive problems such as pulmonary edema
- Questionable anatomic or physiologic abnormalities
- Planned cardiac surgery
- Progressive monitoring related to pulmonary hypertension
- Periodic assessment after repair of a cardiac defect
- Therapeutic interventions such as septostomy or balloon valvotomy

Cardiac catheterization may be categorized as diagnostic, interventional, or electrophysiologic. Diagnostic cardiac catheterization typically is used to identify structural defects. Interventional cardiac catheterization is used as a treatment measure to dilate occluded or stenotic structures or vessels or close some defects. Electrophysiologic cardiac catheterization involves the use of electrodes to identify abnormal rhythms and destroy sites of abnormal electrical conduction. The type of catheterization performed varies based on the individual needs of the patient. The procedure lasts from 1 to 3 hours (Driscoll, 2006; Mullins, 2006b; Muscari, 2004).

Performing Cardiac Catheterization

In cardiac catheterization, a radiopaque catheter is inserted into a blood vessel and is then guided through the vessel to the heart with the aid of fluoroscopy. For a right-sided catheterization, the catheter is threaded to the right atrium via a major vein such as the femoral vein. With a left-sided catheterization, the catheter is threaded to the aorta and heart via an artery. Once the tip of the catheter is in the heart, contrast material is injected via the catheter and radiographic images are taken.

While the catheter is in the heart, several procedures can be performed. The blood pressures, changes in cardiac output or stroke volume, and oxygen saturation in each heart chamber and major blood vessels are recorded. With the injection of contrast material, information is revealed about the heart anatomy, ventricular wall motion and ejection fraction, intracardiac pressures and hemodynamic parameters, cardiac valve function, and structural abnormalities. The movement of the contrast material is filmed so that the details of the cardiac procedure are recorded. Samples of heart tissue to evaluate for infection, muscular dysfunction, or rejection after a transplant may also be obtained.

Nursing Management

Although cardiac catheterization may be considered nearly routine, for the child and parents or guardians, the procedure can be a source of much anxiety. Therefore, the nurse needs to educate the parents and, if appropriate for age, the child about all aspects of the procedure. The procedure is commonly performed on an outpatient basis, but some health care providers require the child be admitted for an overnight stay for observation. Nursing management of the child undergoing cardiac catheterization includes preprocedure nursing assessment and preparation of the child and family, postprocedural nursing care, and discharge teaching.

Before the Procedure. A thorough history and physical examination are necessary to establish a baseline. Obtain vital signs. Note fever or other signs and symptoms of infection, which may necessitate rescheduling the procedure. Obtain the child's height and weight to aid in determining medication dosages. Assess the child for any allergies, especially to iodine and shellfish, because some contrast materials contain iodine as a base. Review the child's medications: medications such as anticoagulants are typically withheld for several days or longer prior to the procedure to reduce the child's risk for bleeding. Check the results of any laboratory tests, such as hemoglobin and hematocrit levels.

Perform a complete physical examination. Pay particular attention to assessing the child's peripheral pulses, including pedal pulses. Use an indelible pen to mark the location of the child's pedal pulses so they can be easily assessed after the procedure. Document the location and quality in the child's medical record.

Teach the parents and child, if appropriate, about the procedure, including what the procedure involves, how long it will take, and any special instructions from the health care provider. Use a variety of teaching methods as appropriate, such as videotapes, books, and pamphlets. Adapt these teaching methods to the child's developmental stage. For example, introduce the younger child to equipment through play therapy. For school-age and older children and their parents, offer a tour of the cardiac catheterization laboratory. Mention sounds and sights they may experience during the procedure. Explain the use of intravenous fluid therapy, sedation, and, if ordered, anesthesia to the child and parents. Tell the child that he or she may feel a sensation of the heart racing when the catheter is inserted. Also warn the older child that he or she may experience a feeling of warmth or stinging when the contrast material is injected. Encourage the child to use familiar ways to help him or her relax. If necessary, teach the child simple relaxation measures.

Typically, food and fluid are withheld for 4 to 6 hours before the procedure. Prescribed medications may be taken with a sip of water. On the day of the procedure, check to ensure that a signed informed consent form is on the child's medical record and that all necessary assessment data have been included. Just before the procedure, ask the child to void and administer a sedative, as ordered. If appropriate and permitted, allow the parents to accompany the child to the catheterization area.

Teach the child and family what to expect after the procedure is completed. Inform the parents of the possible complications that might occur, such as bleeding, low-grade fever, loss of pulse in the extremity used for the catheterization, and arrhythmias. Explain to the child that he or she will have a dressing over the catheter site and that he or she will need to keep the leg straight for several hours after the procedure. Teach the child and parent that frequent monitoring will be required after the procedure.

After the Procedure. Throughout the postprocedure period, closely monitor the child for complications of bleeding, **arrhythmia**, hematoma and thrombus formation, and infection. After the procedure, evaluate the child's vital signs, the neurovascular status of the lower extremities, and the pressure dressing over the catheterization site every 15 minutes for the first hour and then every 30 minutes for 1 hour. Vital signs should remain within acceptable parameters. Hypotension may signify hemorrhage due to perforation of the heart muscle or bleeding from the insertion site. Expect to monitor cardiac rhythm and oxygen saturation levels via pulse oximetry for the first few hours after the procedure to help identify possible complications.

Assess the child's distal pulses bilaterally for presence and quality. The pulse of the affected extremity may be slightly less than that of the other extremity in the initial postprocedure period, but it should gradually return to baseline. Also assess the color and temperature of the extremity; pallor or blanching would indicate an obstruction in blood flow. Check capillary refill and sensation to evaluate blood flow to the area.

Maintain bed rest in the immediate postprocedure period. Ensure that the child maintains the extremity in a straight position for approximately 4 to 8 hours, depending on the approach used and the facility's policy. Some facilities require straight positioning for 4 to 6 hours after a right-sided catheterization and for 6 to 8 hours after a left-sided catheterization to ensure healing of the vessel. Inspect the pressure dressing frequently. Check to make sure that it is dry and intact, without evidence of bleeding. Reinforce the dressing as necessary and report any evidence of drainage on the dressing. If there is a risk of the dressing becoming soiled or wet, cover it with plastic.

▶ *Take* NOTE!

If bleeding occurs after a cardiac catheterization, apply pressure 1 inch above the site to create pressure over the vessel, thereby reducing the blood flow to the area.

Monitor the child's intake and output closely to ensure adequate hydration. The contrast material has a diuretic effect, so assess the child for signs and symptoms of dehydration and hypovolemia. Typically, the child resumes oral intake as tolerated, beginning with sips of clear liquids and progressing to his or her preprocedure diet. Continue intravenous fluids as ordered and encourage oral fluid intake as allowed and ordered to promote elimination of the contrast material.

Allow the child to talk about the experience and how and what he or she felt. Provide positive reinforcement for the child's actions.

Provide patient and family education before the child is discharged home (Teaching Guidelines 40.1). Areas to address include site care, signs and symptoms of complications (especially within 24 hours after the catheterization, such as fever, bleeding or bruising at the catheterization site, or changes in color, temperature, or sensation in the extremity used), diet, and activity level.

TEACHING GUIDELINES 40.1

Providing Care After a Cardiac Catheterization

- Change the pressure dressing on the day after the procedure. Apply a dry sterile dressing or adhesive bandage for the next several days. Keep the dressing dry; cover it with plastic if there is a chance that the dressing could become wet or soiled.
- When changing the dressing, inspect the insertion site for redness, irritation, swelling, drainage, and bleeding. Report any of these to the health care provider.
- Check the temperature, color, sensation, and pulses on the child's extremities and compare. Report any changes to the health care provider.
- Resume the child's usual diet after the procedure; report any nausea or vomiting.
- Check the child's temperature at least once a day for approximately 3 days after the procedure. Report any temperature elevation of 100.4°F or greater.
- Avoid giving the child a tub bath for approximately 3 days after the procedure; use sponge baths or showers instead.
- Discourage strenuous exercise or activity for approximately 3 days after the procedure.
- Watch for changes in the child's appearance, such as changes in skin color, reports of the heart "fluttering" or "skipping a beat," fever, or difficulty breathing.
- Give acetaminophen (Tylenol) or ibuprofen (Motrin) for complaints of pain.
- Schedule a follow-up appointment with the health care provider in the time specified.

Nursing Diagnoses and Related Interventions

Upon completion of a thorough assessment, the nurse might identify several nursing diagnoses. These may include but are not limited to:

- Decreased cardiac output
- Ineffective tissue perfusion
- Imbalanced nutrition, less than body requirements
- Risk for delayed growth and development
- Risk for infection
- Excess fluid volume
- Interrupted family process
- Activity intolerance
- Pain

After completing Logan's assessment, the nurse noted the following: poor weight gain, tachypnea with occasional nasal flaring, crackles heard on auscultation, and edema noted in the face, presacral area and extremities. Based on these assessment findings, what would your top three nursing diagnoses be for Logan?

Nursing goals, interventions, and evaluation for the child with a cardiovascular disorder are based on the nursing diagnoses. Nursing Care Plan 40.1 can be used as a guide in planning nursing care for the child with a cardiovascular disorder. The nursing care plan overview should be individualized based on the patient's symptoms and needs. Refer to Chapter 35 for detailed information about pain assessment and management. Additional information will be included later in the chapter as it relates to specific disorders.

Based on your top three nursing diagnoses for Logan, describe appropriate nursing interventions.

Congenital Heart Disease

In North America, more than 1% of newborn infants have CHD resulting from numerous causes. The prevalence of CHD is about 8 per 1,000 live births; premature infants have a higher rate (Fixler, 2006). Many chromosome defects are associated with CHD, including Down syndrome, velocardiofacial syndrome, Turner syndrome, trisomy 13, trisomy 18, Williams syndrome, Prader-Willi syndrome, and cri-du-chat (Marian et al., 2004). About one third of infants with CHD will have disease serious enough to result in death or will require cardiac catheterization or cardiac surgery within the first year of life.

(text continues on page 1295)

Nursing Care Plan 40.1

Overview for the Child With a Cardiovascular Disorder

NURSING DIAGNOSIS: Decreased cardiac output related to structural defect, congenital anomaly, or ineffective heart pumping as evidenced by arrhythmias, edema, murmur, abnormal heart rate, or abnormal heart sounds

Outcome Identification and Evaluation

Child or infant will demonstrate adequate cardiac output; *will have elastic skin turgor, brisk capillary refill, demonstrate pink color, pulse and blood pressure within normal limits for age, regular heart rhythm, adequate urinary output.*

Interventions: Increasing Cardiac Output

- Monitor vital signs closely, especially BP and heart rate, *to detect increases or decreases.*
- Monitor cardiac rhythm via cardiac monitor *to detect arrhythmias quickly.*
- Observe for signs of hypoxia such as tachypnea, cyanosis, tachycardia, bradycardia, dizziness, and/or restlessness *to identify this change early.*
- Administer oxygen as needed *to correct hypoxia.*
- Place child in knee-to-chest or squatting position as needed *to increase systemic vascular resistance.*
- Administer antiarrhythmics, vasopressors, ACE inhibitors, beta blockers, corticosteroids, or diuretics as prescribed *to improve cardiac output.*
- Monitor for signs of thrombosis such as restlessness, seizure, coma, oliguria, anuria, edema, hematuria, or paralysis *to identify this condition early.*
- Administer adequate hydration *to decrease possibility of thrombosis formation.*
- Cluster nursing care and other activities *to allow adequate periods of rest.*
- Anticipate child's needs *to decrease the child's stress, thereby decreasing oxygen consumption requirement.*

NURSING DIAGNOSIS: Excess fluid volume related to ineffective cardiac muscle function as evidenced by weight gain, edema, jugular vein distention, dyspnea, shortness of breath, abnormal breath sounds, or pulmonary congestion

Outcome Identification and Evaluation

Child will attain appropriate fluid balance, *will lose weight (fluid), edema or bloating will decrease, lung sounds will be clear and heart sounds normal.*

Interventions: Encouraging Fluid Loss

- Weigh daily on same scale in similar amount of clothing; *in children weight is the best indicator of changes in fluid status.*
- Monitor location and extent of edema (measure abdominal girth daily if ascites is present); *decrease in edema indicates positive increase in oncotic pressure.*
- Protect edematous areas from skin breakdown: *edema leads to increased risk for alterations in skin integrity.*
- Auscultate lungs carefully to identify crackles *(indicating pulmonary edema).*
- Assess work of breathing and respiratory rate *(increased work of breathing is associated with pulmonary edema).*
- Assess heart sounds for gallop *(presence of S3 may indicate fluid overload).*
- Maintain fluid restriction as ordered *to decrease intravascular volume and workload on the heart.*
- Strictly monitor intake and output *to quickly note discrepancies and provide intervention.*
- Provide sodium-restricted diet as ordered *(restricting sodium intake allows better renal excretion of extra fluid).*
- Administer diuretics as ordered and monitor for adverse effects. *Diuretics encourage excretion of fluid, elimination of edema, reduce cardiac filling pressures, and increase renal blood flow. Adverse effects include electrolyte imbalance as well as orthostatic hypotension.*

Nursing Care Plan 40.1 (continued)

NURSING DIAGNOSIS: Imbalanced nutrition, less than body requirements, related to increased energy expenditure and fatigue as evidenced by weight loss or height and weight below accepted standards

Outcome Identification and Evaluation

Child will improve nutritional intake resulting in *steady increase in weight and length/height, will feed without tiring easily.*

Interventions: Promoting Adequate Nutrition

- Determine body weight and length/height norm for age *to determine goal to work toward.*
- Assess child for food preferences that fall within dietary restrictions: *child will be more likely to consume adequate amounts of foods that he or she likes.*
- Weigh child daily or weekly (according to physician order or institutional standard) and measure length/height weekly *to monitor for increased growth.*
- Offer highest-calorie meals at the time of day when the child's appetite is the greatest *(to increase likelihood of increased caloric intake).*
- Provide increased-calorie shakes or puddings within diet restriction *(high-calorie foods increase weight gain).*
- Consult with the pediatric dietician *to provide optimal caloric intake within dietary restrictions.*
- Provide small, frequent feedings *to discourage tiring with feeding.*
- Feed infants with special nipple as needed *to decrease amount of energy expended for sucking.*
- Administer vitamin and mineral supplements as prescribed *to attain/maintain vitamin and mineral balance in the body.*

NURSING DIAGNOSIS: Ineffective tissue perfusion related to inadequate cardiac function or cardiac surgery as evidenced by pallor, cyanosis, edema, changes in mental status, prolonged capillary refill, clubbing, or diminished pulses

Outcome Identification and Evaluation

Child will demonstrate adequate tissue perfusion: *Child will be alert, not restless or lethargic, will have pink color, decrease in edema, normal perfusion and strong pulses.*

Interventions: Promoting Tissue Perfusion

- Assess level of consciousness, pulse, BP, peripheral perfusion, and skin color frequently *to determine baseline and ongoing improvement.*
- Administer cardiac glycosides or vasodilators as ordered *to promote cardiac output necessary for proper perfusion.*
- Monitor pulse oximetry and arterial blood gas results *to assess ability to appropriately oxygenate.*
- Supplement oxygen as needed *to provide oxygen to organs for proper functioning.*
- Monitor hemoglobin and hematocrit *to identify blood loss.*
- Strictly assess intake and output *to determine adequacy of renal perfusion.*
- Position with head of bed elevated *to decrease blood volume returning to heart.*
- Change position every 2 to 4 hours *to promote circulation and avoid skin breakdown in areas of poor perfusion.*

NURSING DIAGNOSIS: Risk for delayed growth and development related to effects of cardiac disease and necessary treatments, inadequate nutrition, or frequent separation from caregivers secondary to illness

Outcome Identification and Evaluation

Child will display development appropriate for age, *will display evidence of cognitive and motor function within normal limits (individualized for each child).*

Interventions: Promoting Appropriate Development

- Promote adequate caloric intake *to stimulate growth and provide adequate energy.*
- Provide age-appropriate developmental activities *to stimulate development.*
- Consult with the physical or occupational therapist or child life specialist *to determine activities most appropriate for the child within the constraints of the child's illness.*
- Schedule daily activities to allow for essential rest periods *for energy conservation.*
- Encourage parents, teachers, and playmates to be sensitive to child's self-image, using positive comments, *to improve the child's self-concept.*
- As energy allows, encourage participation in all activities as feasible *to allow the child to feel normal.*

(continued)

Nursing Care Plan 40.1 (continued)

NURSING DIAGNOSIS: Risk for infection related to need for multiple invasive procedures or cardiac surgery as evidenced by break in skin integrity, decreased hemoglobin, or inadequate nutritional intake

Outcome Identification and Evaluation

Child will remain free from infection: *vital signs will be within normal limits, white blood cell count normal, cultures negative. Child will exhibit no signs or symptoms of infection.*

Interventions: Preventing Infection

- Maintain strict hand hygiene *to prevent spread of infectious organisms to the child.*
- Assess temperature *to detect elevation early in course of infection.*
- Avoid contact with persons with known infections *to prevent risk of becoming ill.*
- Ensure appropriate immunization, including pneumococcal and influenza vaccinations, *to prevent development of common childhood illness.*
- Administer prophylactic antibiotics prior to all dental procedures, surgery, and many invasive procedures *to prevent subacute bacterial endocarditis.*
- Encourage good dental hygiene *to reduce the risk of endocarditis.*

NURSING DIAGNOSIS: Interrupted family processes related to crisis associated with heart disease, frequent need for testing and hospitalizations, or stresses associated with care demands, as evidenced by inadequate parental coping, frequent separations of parent and child, or inadequate support

Outcome Identification and Evaluation

Family will maintain functional system of support and will demonstrate adequate coping, adaptation of roles and functions, and decreased anxiety: *Parents are involved in child's care, ask appropriate questions, express fears and concerns, and can discuss child's care and condition calmly.*

Interventions: Promoting Family Processes

- Provide ongoing support to the child and family *to help them cope.*
- Encourage parents and family members to verbalize concerns related to child's illness, diagnosis, and prognosis: *allows the nurse to identify concerns and areas where further education may be needed. Demonstrates family-centered care.*
- Allow families to grieve over the loss of a "perfect" child: *parents must work through those grief feelings so they can be fully "present" for this chronically ill child.*
- Explain therapies, procedures, child's behaviors, and plan of care to parents: *understanding the child's current status and plan of care helps decrease anxiety.*
- Encourage parents to be involved in care: *allows parents to feel needed and valued and gives them a sense of control over their child's health.*
- Identify support system for family and child: *helps nurse identify needs and resources available for coping.*
- Educate family and child on additional resources available *to help them develop a wide base of support.*
- Encourage parents to seek genetic counseling *to provide them with the information required to make an informed decision about having another child.*

Nursing Care Plan 40.1 (continued)

NURSING DIAGNOSIS: Activity intolerance related to ineffective cardiac muscle function, increased energy expenditure, or inability to meet increased oxygen or metabolic demands as evidenced by squatting positions, shortness of breath, cyanosis, or fatigue

Outcome Identification and Evaluation

Child will increase activity level as tolerated: *child participates in play and activities (specify particular activities and level as individualized for each child).*

Interventions: Promoting Activity

- Assess level of fatigue and activity tolerance *to determine baseline for comparison.*
- Note extent of dyspnea, oxygen requirement, or color change with exertion *to provide baseline for comparison.*
- Cluster care activities, allowing rest periods in between, *to conserve child's energy.*
- Work with the parent and child to determine a mutually satisfactory daily schedule *to allow adequate rest and energy conservation.*
- Instruct family and child in prescribed activity restrictions *to prevent fatigue while allowing some activity.*
- In the infant, avoid long periods of crying or prolonged nipple feeding *(expends excessive calories).*
- Provide neutral thermal environment *to avoid increased oxygen and energy needs associated with excessive heat or cold.*

Complications of CHD include heart failure, hypoxemia, growth retardation, developmental delay, and pulmonary vascular disease. As many as 13% of children with CHD experience severe failure to thrive (Chen et al., 2004).

With advances in palliative and corrective surgery in the past 20 years, many more children are now able to survive into adulthood (Fulton & Freed, 2004). As many as 70% to 85% of children with CHD grow to be adults, yet many have problems related to education, insurance, and employment (McDonagh, 2005). Hypothermia and cardiopulmonary bypass required during cardiac surgery for CHD may have a long-term impact on the child's cognitive ability and academic function (Mahle et al., 2006). Due to the potential long-term effects that CHD may have on these children, nurses must be expertly equipped to care for them.

Pathophysiology

The exact cause of CHD is unknown. However, the belief is that it results from an interplay of several factors, including genetics (e.g., chromosomal alterations) and maternal exposure to environmental factors (e.g., toxins, infections, chronic illnesses, and alcohol).

Congenital heart defects result from some interference in the development of the heart structure during fetal life. Subsequently, the septal walls or valves may fail to develop completely, or vessels or valves may be stenotic, narrowed, or transposed. Structures that formed to allow fetal circulation may fail to close after birth, altering the pressures necessary to maintain adequate blood flow.

After birth, with the change from fetal to newborn circulation, pressures within the chambers of the right side of the heart are less than those of the left side and pulmonary vascular resistance is less than that for the systemic circulation. These normal pressure gradients are necessary for adequate circulation to the lungs and the rest of the body. However, these pressure gradients become disrupted if a structure has failed to develop, a fetal structure has failed to close, or a narrowing, stenosis, or transposition of a vessel has occurred. For example, blood typically flows from an area of higher pressure to lower pressure. If the ductus arteriosus fails to close, blood will move from the aorta to the pulmonary artery, ultimately increasing right atrial pressure. With this shunting of blood, highly oxygenated blood can mix with less oxygenated blood, interfering with the amount available to the tissues via the systemic circulation. Some of the defects may result in significant hypoxemia, the sequelae of which include clubbing, polycythemia, exercise intolerance, hypercyanotic spells, brain abscess, and cerebrovascular accident (Fulton & Freed, 2004).

The traditional approach to categorizing CHD has been in terms of whether the child exhibits cyanosis as a clinical manifestation—cyanotic versus acyanotic defects. However, children with acyanotic defects may exhibit cyanosis, and children with cyanotic defects may not demonstrate cyanosis unless they are seriously ill. Many children with congenital heart defects shift between cyanotic and acyanotic states depending on their hemodynamic status (Suddaby, 2001). Therefore, this chapter will categorize the disorders based on hemodynamic characteristics (blood flow patterns in the heart):

- Disorders with decreased pulmonary blood flow: tetralogy of Fallot, tricuspid atresia
- Disorders with increased pulmonary blood flow: patent ductus arteriosus (PDA), atrial septal defect (ASD), ventricular septal defect (VSD)

- Obstructive disorders: coarctation of the aorta, aortic stenosis, pulmonary stenosis
- Mixed disorders: transposition of the great vessels (TGV), total anomalous pulmonary venous return (TAPVR), truncus arteriosus, and hypoplastic left heart syndrome (Suddaby, 2001)

Therapeutic Management

Prenatal education about avoiding certain substances or infection is essential to promote optimal outcomes for the fetus. Parents of children with CHD are encouraged to receive genetic counseling because of the probability of having subsequent children with a congenital heart defect. Children with small septal defects are urged to lead a normal life and often require no medical intervention. Therapeutic management of other forms of CHD focuses on palliative care or a surgical corrective approach necessary for most of the defects. In newborns and very young infants with severe cyanosis (tricuspid atresia, TGV), a prostaglandin infusion will maintain patency of the ductus arteriosus, improving pulmonary blood flow. Definitive correction of structural disorders requires surgical intervention. Table 40.2 describes the surgical procedures used for the various congenital heart defects and the relevant nursing measures. Nursing management for the child with CHD will be provided following the disorders section. See Evidence-Based Practice.

DISORDERS WITH DECREASED PULMONARY BLOOD FLOW

Defects involving decreased pulmonary blood flow occur when there is some obstruction of blood flow to the lungs. As a result of the obstruction, pressure in the right side of the heart increases and becomes greater than that of the left side of the heart. Blood from the higher-pressure right side of the heart then shunts to the lower-pressure left side through a structural defect. Subsequently, deoxygenated blood mixes with oxygenated blood on the left side of the heart. This mixed blood, which is low in oxygen, is pumped via the systemic circulation to the body tissues.

Defects with decreased pulmonary blood flow are characterized by mild to severe oxygen desaturation. Typically, the child exhibits oxygen saturation levels ranging from 50% to 90%, which can produce severe cyanosis. To compensate for low blood oxygen levels, the kidneys produce the hormone erythropoietin to stimulate the bone marrow to produce more red blood cells (RBCs). This increase in RBCs is called **polycythemia**. Polycythemia can lead to an increase in blood volume and possibly blood viscosity, further taxing the workload of the heart. Although the number of RBCs increases, there is no change in the amount of blood that reaches the lungs for oxygenation (Chamberlain, 2006; Driscoll, 2006a). Disorders within this classification include tetralogy of Fallot and tricuspid atresia.

Tetralogy of Fallot

Tetralogy of Fallot is a congenital heart defect that actually comprises four heart defects: pulmonary stenosis (a narrowing of the pulmonary valve and outflow tract, creating an obstruction of blood flow from the right ventricle to the pulmonary artery), VSD, overriding aorta (enlargement of the aortic valve to the extent that it appears to arise from the right and left ventricles rather than the anatomically correct left ventricle), and right ventricular hypertrophy (the muscle walls of the right ventricle increase in size due to continued overuse as the right ventricle attempts to overcome a high pressure gradient). Surgical intervention is usually required during the first year of life. The rate for survival into adulthood with a good functional long-term result is greater than 90% (Neches et al., 2006a).

Pathophysiology

With pulmonary stenosis, the blood flow from the right ventricle is obstructed and slowed, resulting in a decrease in blood flow to the lungs for oxygenation and a decrease in the amount of oxygenated blood returning to the left atrium from the lungs. The obstructed flow also increases the pressure in the right ventricle. This blood, which is poorly oxygenated, is then shunted across the VSD into the left atrium. Poorly oxygenated blood also travels through the overriding aorta (if it extends to both ventricles). In some cases when the VSD is large, the pressure in the right ventricle may be equal to that of the left ventricle. In this case, the path of blood shunting depends on which circulation is exerting the higher pressure, pulmonary or systemic.

Regardless of which way shunting occurs, a mixing of oxygenated and poorly oxygenated blood occurs, with this blood ultimately being pumped into the systemic circulation. The oxygen saturation of the blood in the systemic circulation is reduced, leading to cyanosis. The degree of cyanosis depends on the extent of the pulmonary stenosis, the size of the VSD, and the vascular resistance of the pulmonary and systemic circulations. In some children, cyanosis is so severe that it leads to severe hypoxia, dysrhythmias, and sudden death (Betz & Sowden, 2005).

Tetralogy of Fallot is usually diagnosed during the first weeks of life due to the presence of a murmur and/or cyanosis. Some newborns may be acutely cyanotic, while others may exhibit only mild cyanosis that gradually becomes more severe, particularly during times of stress as the child grows older. Most often, infants with tetralogy of Fallot have a PDA at birth, providing additional pulmonary blood flow and thereby decreasing the severity of the initial cyanosis. Later, as the ductus arteriosus closes, such as within the first days of life, more severe cyanosis can occur (Fig. 40.2).

(text continues on page 1299)

TABLE 40.2 Common Surgical Procedures and Nursing Measures for Congenital Heart Defects

Disorder	Surgical Procedure	Nursing Measures
Tetralogy of Fallot	Palliation with systemic-to-pulmonary anastomoses: • Blalock-Taussig shunt: an end-to-side anastomosis (or connection with a small Gore-tex tube) of the subclavian artery and the pulmonary artery. • Waterston shunt: anastomosis of the ascending aorta and the pulmonary artery. • Definitive correction involves patch closure of the ventricular septal defect and repair of the pulmonary valve and right ventricular outflow tract.	• Avoid BP measurements and venipunctures in the affected arm after a Blalock-Taussig shunt. Pulse will not be palpable in that arm because of use of the subclavian artery for the shunt. • Monitor for ventricular arrhythmias after corrective repair.
Tricuspid atresia	• Palliation with Blalock-Taussig shunt or pulmonary artery banding may be performed. • At 3 to 6 months of age, the superior vena cava is detached from the heart and connected to the pulmonary artery (Glenn procedure). • By age 2 to 5 years, a modified Fontan procedure may be performed. Systemic venous return is redirected to the pulmonary artery directly.	• Monitor for atrial arrhythmias, left ventricular dysfunction, and protein-losing enteropathy. • Some children may eventually require a pacemaker.
Atrial septal defect	• If small, the defect may be sutured closed. Larger defects may require a patch of pericardium or synthetic material. • Ostium secundum ASD may be repaired percutaneously via cardiac catheterization with an Amplatzer septal occluder (other brands are also available).	• Monitor for atrial arrhythmias (lifelong) after surgical closure. • With the Amplatzer device, strenuous activity should be avoided for 1 month after the procedure.
Ventricular septal defect	• If surgical closure is required, it should be performed before permanent pulmonary vascular changes develop. • Surgical closure may be in the form of suture closure of the VSD, transcatheter placement of a device in the defect, or Dacron patch closure.	• Monitor for ventricular dysrhythmias or AV block. • With the clamshell occluding or Amplatzer device, strenuous activity should be avoided for 1 month after the procedure.
Atrioventricular canal defect	• Pulmonary artery banding as palliation in very young infants. • Surgical correction by 3 to 18 months of age. • Patch closure of the septal defects and suturing of the valve leaflets or valve reconstruction are performed.	• Monitor for complete heart block postoperatively. • Teach parents that mitral regurgitation is a long-term complication and may require valve replacement.
Patent ductus arteriosus	• PDA is closed by coil embolization or device via cardiac catheterization. • May also be surgically ligated.	• Monitor for bleeding and laryngeal nerve damage.
Coarctation of the aorta	• Balloon angioplasty via cardiac catheterization is possible in some children. • Most common surgical repair is resection of the narrowed portion of the aorta, followed by end-to-end reanastomosis.	• Preoperatively, administer prostaglandin medications as ordered to relax the ductal tissue. • Postoperatively, measure and compare BP in all four extremities and quality of upper vs. lower pulses.
Aortic stenosis	• Balloon dilatation is accomplished via the umbilical artery in the newborn or the femoral artery via cardiac catheterization in the older child.	• Provide routine post-catheterization care. • Teach parents that long-term aortic regurgitation requiring valve replacement may occur.

TABLE 40.2 COMMON SURGICAL PROCEDURES AND NURSING MEASURES FOR CONGENITAL HEART DEFECTS (continued)

Disorder	Surgical Procedure	Nursing Measures
Pulmonary stenosis	• Balloon dilation valvuloplasty is performed via cardiac catheterization to dilate the valve. This is effective in all but the most severe of cases, which will require surgical valvotomy.	• Provide routine post-catheterization care for balloon dilation. • Explain to parents that prognosis is excellent.
Transposition of the great vessels (arteries)	• Balloon atrial septotomy is usually done as soon as the diagnosis is made. A balloon-tipped catheter is passed through the atrial septum to enlarge the atrial septum. • Surgical correction involves switching the arteries into their normal anatomic positions.	• Administer prostaglandin to maintain the open state of the ductus arteriosus, which will allow the mixing of poorly oxygenated blood with well-oxygenated blood. • Monitor for rapid respirations and cyanosis. • Administer oxygen as needed preoperatively.
Total anomalous pulmonary venous return	The pulmonary vein is repositioned to the back of the left atrium and the ASD is closed.	• Monitor for dysrhythmias, heart block, and persistent heart failure.
Truncus arteriosus	VSD repair, separation of the pulmonary arteries from the aorta, with subsequent connection to the right ventricle with a valve conduit.	• Preoperatively, administer prostaglandin infusion to prevent closing of the ductus arteriosus.
Hypoplastic left heart syndrome	• Heart transplantation is the treatment of choice. • Palliative staged treatment. First: Norwood procedure, reconstruction of the aorta and pulmonary arteries includes a cardiac transplant. Second: bidirectional Glenn procedure, connection of the superior vena cava to the right pulmonary artery to increase the blood flow to the lungs. Third: modified Fontan procedure.	• Preoperatively, administer prostaglandin infusion to prevent closing of the ductus arteriosus. • After palliative repairs, monitor for dysrhythmias or worsening ventricular function.
Valve disorders	• The incompetent valve is replaced with a valve prosthesis.	• Lifelong anticoagulation therapy is necessary with prosthetic valves. • Monitor prothrombin times. • Monitor heart sounds for alterations.

EVIDENCE-BASED PRACTICE 40.1
Effects of Chronic or Intermittent Hypoxia on Cognition in Children

● Study
It is well known that significant hypoxia demonstrates an adverse effect on cognition, yet little is known about the effects of chronic or intermittent hypoxia on cognition in children. Many children with congenital heart disease (CHD) suffer either chronic or intermittent hypoxia. The authors performed a systematic literature review to study this question. Fifty-five studies were included, and a significant proportion of them addressed hypoxia with CHD.

▲ Findings
About 80% of the studies reported adverse effects on cognition in children who suffered chronic or intermittent hypoxia, including developmental and academic achievement. Adverse effects were noted at all childhood age levels except premature infants. The effects were noted even with mild oxygen desaturation.

■ Nursing Implications
It is critical that the developing child be afforded the opportunity to develop optimal cognition. Know the child's normal oxygen saturation so that decreases may be quickly acted upon. Use supplemental oxygen judiciously and within the physician order parameters. Since many children experience improved oxygenation after CHD repair, encourage adequate nutrition so that, in turn, the infant or child will demonstrate growth adequate for safe surgical intervention.

Bass, J. L., Corwin, M., Gozal, D., Moore, C., Nishida, H., Parker, S., Schonwald, A., Wilker, R. E., Stehle, S., & Kinane, T. B. (2004). The effect of chronic or intermittent hypoxia on cognition in childhood: A review of the evidence. *Pediatrics, 114*(3), 805–816.

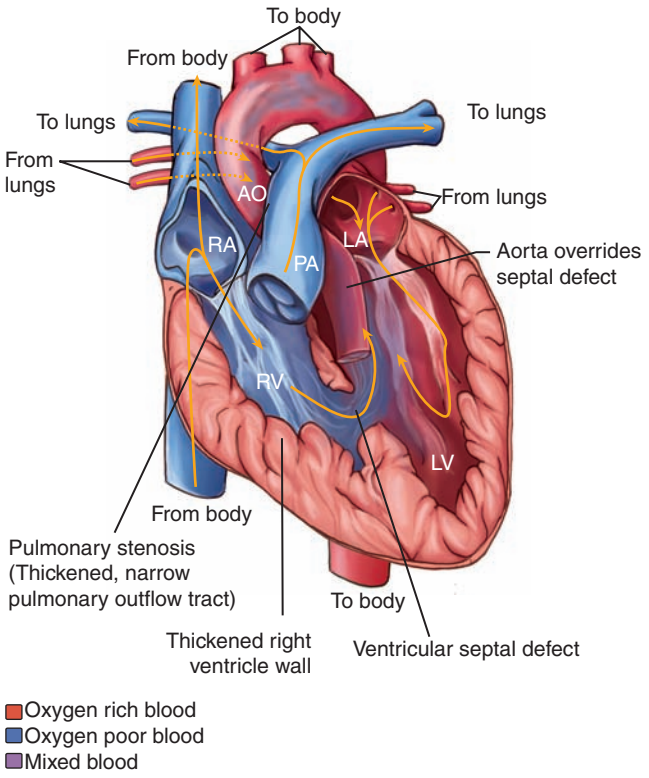

FIGURE 40.2 Tetralogy of Fallot.

Nursing Assessment

Nursing assessment consists of health history, physical examination, and laboratory and diagnostic tests.

Health History and Physical Examination

Obtain the health history, noting a history of color changes associated with feeding, activity, or crying. Determine if the infant or child is demonstrating hypercyanotic spells. Hypercyanosis develops suddenly and is manifested as increased cyanosis, hypoxemia, dyspnea, and agitation. If the infant's oxygen demand is greater than the supply, such as with crying or during feeding, then the spell progresses to anoxia. When the degree of cyanosis is severe and persistent, the infant may become unresponsive. As the infant gets older, he or she may use specific postures, such as bending at the knees or assuming the fetal position, to relieve a hypercyanotic spell. The walking infant or toddler may squat periodically. These positions improve pulmonary blood flow by increasing systemic vascular resistance. Ask the parents if they have noticed any of these unusual positions (Driscoll, 2006a). Note history of irritability, sleepiness, or difficulty breathing.

During the physical examination, observe the skin color and note any evidence of cyanosis. Also observe for changes in skin color with positional changes, and inspect the fingers for clubbing. Note if the child has a hypercyanotic spell during the assessment. Count the child's respiratory rate and observe work of breathing, noting retractions, shortness of breath, or noisy breathing. Document oxygen saturation via pulse oximetry; it will likely be decreased. Auscultate the chest for adventitious breath sounds, which may suggest the development of heart failure. Auscultate the heart, noting a loud, harsh murmur characteristic of this disorder.

Laboratory and Diagnostic Tests

Note increased hematocrit, hemoglobin, and RBC count associated with polycythemia. Additional testing may include:

- Echocardiography, possibly revealing right ventricular hypertrophy, decreased pulmonary blood flow, and reduced size of the pulmonary artery
- ECG, indicating right ventricular hypertrophy
- Cardiac catheterization and angiography, which reveal the extent of the structural defects

▶ *Consider THIS!*

Ava Gardener, 2 weeks old, is brought to the clinic by her mother. She presents with trouble feeding. Her mother states, "When Ava eats, she seems to have trouble breathing, and recently I've noticed a bluish color around her lips." What other assessment information would you obtain?

Ava is to be admitted to the hospital secondary to suspected tetralogy of Fallot. What education and interventions may be necessary for this child and family? How can you assist the family to cope?

Tricuspid Atresia

Tricuspid atresia is a congenital heart defect in which the valve between the right atrium and right ventricle fails to develop. As a result, there is no opening to allow blood to flow from the right atrium to the right ventricle and subsequently through the pulmonary artery into the lungs.

Pathophysiology

In tricuspid atresia, blood returning from the systemic circulation to the right atrium cannot directly enter the right ventricle due to agenesis of the tricuspid valve. Subsequently, deoxygenated blood then passes through an opening in the atrial septum (either an ASD or through a patent foramen ovale) into the left atrium, never entering the pulmonary vasculature. Thus, deoxygenated blood mixes with oxygenated blood in the left atrium. The blood then travels to the lungs through a PDA. The foramen ovale and ductus arteriosus must remain open for the newborn to maintain minimally adequate oxygenation (Fig. 40.3).

Nursing Assessment

Nursing assessment consists of health history, physical examination, and laboratory and diagnostic tests.

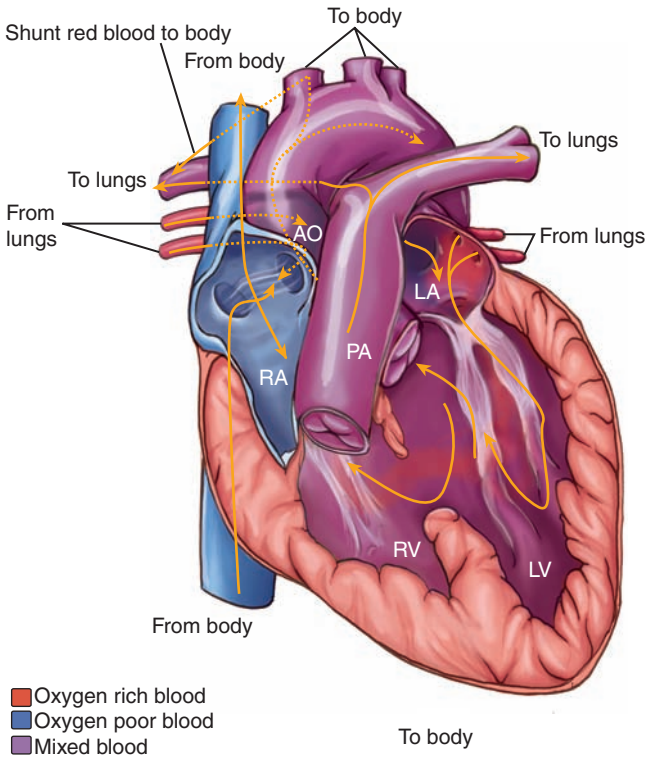

FIGURE 40.3 Tricuspid atresia.

Health History and Physical Examination

Note the infant's history since birth. Document history of cyanosis either at birth or a few days later when the ductus arteriosus closed. Note history of rapid respirations and difficulty with feeding. Inspect the skin for cyanosis or a pale gray color. Observe the apical impulse, noting overactivity. Evaluate the baby's sucking strength (will usually have a weak or poor suck). Count the respiratory rate, noting tachypnea. Note increased work of breathing. Auscultate the lungs, noting crackles or wheezes if heart failure is beginning to develop. Auscultate the heart, noting a murmur. Palpate the skin, noting coolness and clamminess of the extremities. Document the presence of clubbing in the older infant or child.

Laboratory and Diagnostic Testing

Laboratory and diagnostic testing is similar to that for tetralogy of Fallot. A complete blood count (CBC) is needed to assess compensatory increases in hematocrit, hemoglobin, and erythrocyte count (RBC) indicating the development of polycythemia. Oxygen saturation levels (typically reduced) may be determined by pulse oximetry or arterial blood gases. Additional testing may include:

- Echocardiography, revealing absence of tricuspid valve, underdeveloped right ventricle
- ECG, indicating possible heart failure
- Cardiac catheterization and angiography, which reveal the extent of the structural defects

DISORDERS WITH INCREASED PULMONARY FLOW

Most congenital heart defects involve increased pulmonary blood flow. Normally, the left side of the heart has a higher pressure than the right side. Defects with connections involving the left and right sides will shunt blood from the higher-pressure left side to the lower-pressure right side. Even a small pressure gradient such as a 1- to 3-mm difference between the left and right sides will produce a movement of blood from the left to the right. In turn, the increase of blood on the right side of the heart will cause a greater amount of blood to move through the heart. If the amount of blood flowing to the lungs is large, the child may develop **heart failure** early in life. In addition, right ventricular hypertrophy may result. Sometimes with ventricular hypertrophy the right side of the heart pumps so forcefully that left-to-right shunting is reversed to right-to-left shunting. If this occurs, deoxygenated blood mixes with oxygenated blood, thereby lowering the overall blood oxygen saturation level.

Excessive blood flow to the lungs can produce a compensatory response such as tachypnea or tachycardia. Tachypnea increases caloric expenditure; poor cellular nutrition from decreased peripheral blood flow leads to feeding problems. Subsequently, the infant experiences poor weight gain, which retards overall growth and development. Increased pulmonary blood flow results in decreased systemic blood flow, so sodium and fluid retention may occur. Increased pulmonary blood flow also places the child at higher risk for pulmonary infections. As the child grows, the continuous increased pulmonary blood flow will cause vasoconstriction of the pulmonary vessels, actually decreasing the pulmonary blood flow. This may lead to pulmonary hypertension. Therefore, preventing the development of pulmonary disease via early surgical correction is essential.

For children with congenital defects with increased pulmonary blood flow, oxygen supplementation is not helpful. Oxygen acts as a pulmonary vasodilator. If pulmonary dilation occurs, pulmonary blood flow is even greater, causing tachypnea, increasing lung fluid retention, and eventually causing a much greater problem with oxygenation. Over time, continuous increased pulmonary blood flow may cause pulmonary vasoconstriction and pulmonary hypertension. Surgical correction is essential before pulmonary disease develops (Driscoll, 2006a; Gumbiner, 2006; Mullins, 2006a; Vick & Bezold, 2006). Examples of defects with increased pulmonary blood flow are ASD, VSD, atrioventricular canal defect, and PDA.

Atrial Septal Defect

An ASD is a passageway or hole in the wall (septum) that divides the right atrium from the left atrium (Fig. 40.4).

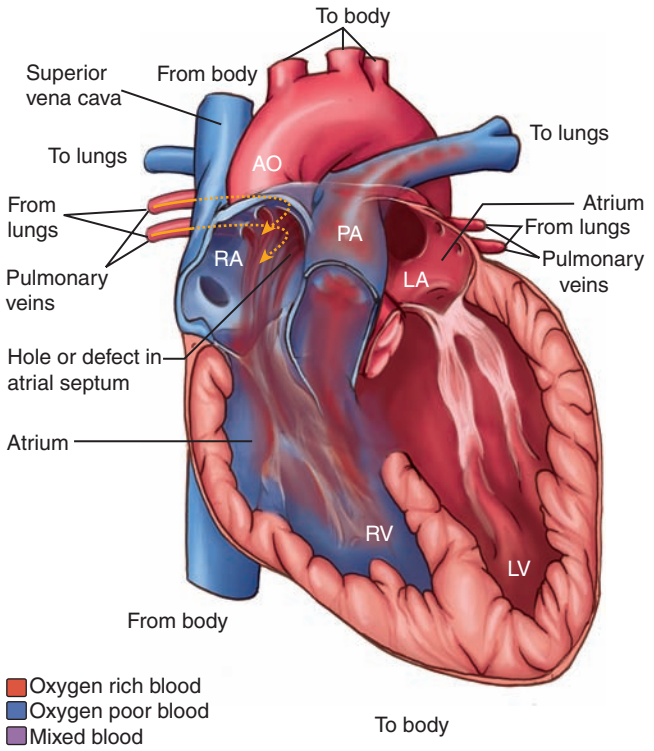

FIGURE 40.4 Atrial septal defect; note the opening between the two atria.

Three types of ASDs are identified based on the location of the opening:

- Ostium primum (ASD1): the opening is at the lower portion of the septum
- Ostium secundum (ASD2): the opening is near the center of the septum
- Sinus venosus defect: the opening is near the junction of the superior vena cava and the right atrium

When the ASD is small, as many as 80% of infants may have a spontaneous closure within the first 18 months of life. If not spontaneously closed by age 3, the child will most likely need corrective surgery.

Pathophysiology

With ASD, blood flows between the opening from the left atrium to the right atrium due to pressure differences. The shunting increases the blood volume entering the right atrium. This, in turn, leads to increased blood flow into the lungs. The defect if untreated can cause problems such as pulmonary hypertension, heart failure, atrial arrhythmias, or stroke (Driscoll, 2006a; Vick & Bezold, 2006).

Nursing Assessment

Most children with ASDs are asymptomatic. However, a very large defect can cause increased blood flow, leading to heart failure, which results in shortness of breath, easy fatigability, or poor growth.

Health History and Physical Examination

Obtain the health history, noting poor feeding as an infant, decreased ability to keep up with peers, or history of difficulty growing. Observe the child's chest, noting a hyperdynamic precordium. Auscultate the heart, noting a fixed split second heart sound and a systolic ejection murmur, best heard in the pulmonic valve area. Palpate along the left sternal border for a right ventricular heave.

Laboratory and Diagnostic Tests

Echocardiography is done to confirm the diagnosis. An **electrocardiogram** may show normal sinus rhythm or prolonged PR intervals. The chest x-ray may show enlargement of the heart and increased vascularity of the lungs.

Ventricular Septal Defect

A VSD is an opening between the right and left ventricular chambers of the heart (Fig. 40.5). It is one of the most common congenital heart defects, with a prevalence of 1.5 to 2.5 per 1,000 live births. VSD accounts for nearly one third of all congenital heart defects (Gumbiner, 2006). Spontaneous closure of the VSD occurs in about 45% of children by age 3 years (most often with smaller defects) (Singh et al., 2004). Long-term outcomes for surgically repaired VSD are good, though the risk of sudden death is increased in those who develop pulmonary hypertension (Roos-Hesselink et al., 2004).

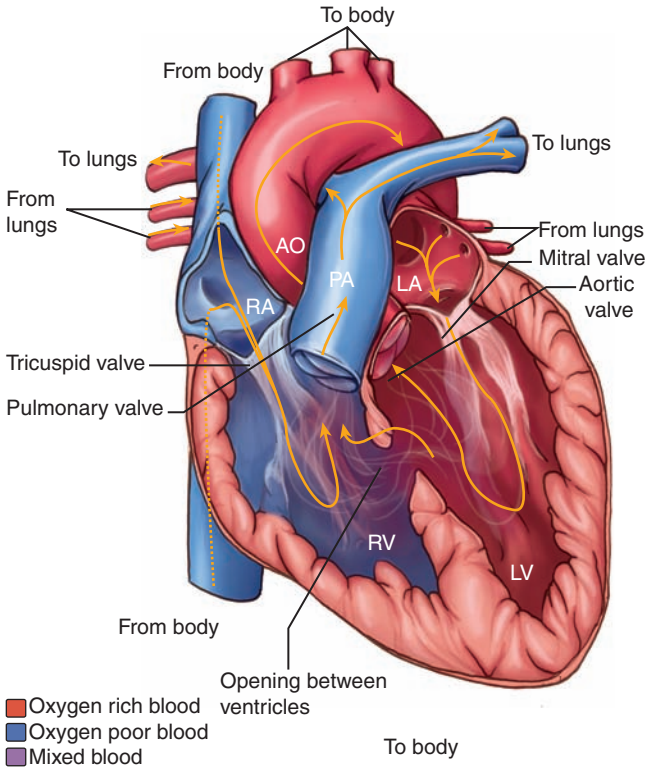

FIGURE 40.5 Ventricular septal defect; note the opening between the ventricles.

Pathophysiology

In VSD, there is an abnormal opening between the right and left ventricles. The opening varies in size, from as small as a pinhole to a complete opening between the ventricles so that the right and left sides are as one. Children with small VSDs may remain asymptomatic. In other children, blood shunts across the opening in the septum. Pulmonary vascular resistance and systemic vascular resistance determine the direction of blood flow. A left-to-right shunt results when pulmonary vascular resistance is low. Increased amounts of blood flowing into the right ventricle are then pumped to the pulmonary circulation, eventually causing an increase in pulmonary vascular resistance. Increased pulmonary vascular resistance leads to increased pulmonary artery pressure (pulmonary hypertension) and right ventricular hypertrophy. When the pulmonary vascular resistance exceeds the systemic vascular resistance, right-to-left shunting of blood across the VSD occurs, resulting in Eisenmenger syndrome (pulmonary hypertension and cyanosis). Heart failure commonly occurs in children with moderate to severe VSD. Children with VSD are also at risk for the development of aortic valve regurgitation as well as infective endocarditis.

Nursing Assessment

Initially, the newborn may not exhibit any signs and symptoms at birth because left-to-right shunting is most likely minimal due to the high pulmonary resistance common after birth.

Health History and Physical Examination

Determine the health history, which commonly reveals signs of heart failure around 4 to 8 weeks of age. Note history of tiring easily, particularly with exertion or feeding. Document the child's growth history, noting difficulty thriving. Ask the parent about color change or diaphoresis with nipple feeding in the infant. Note history of frequent pulmonary infections, shortness of breath, and possibly edema. Inspect the extremities for edema, noting whether pitting is present. Note mild tachypnea.

Auscultate the heart, noting a characteristic holosystolic harsh murmur along the left sternal border. In some instances, a murmur may be noted only with excessive blood flow across the opening. Adventitious lung sounds may be auscultated if the child is experiencing heart failure. Palpate the chest for a thrill.

Laboratory and Diagnostic Tests

Magnetic resonance imaging (MRI) or echocardiogram with color flow Doppler may reveal the opening as well as the extent of left-to-right shunting. These studies also may identify right ventricular hypertrophy and dilation of the pulmonary artery resulting from the increased blood flow. Cardiac catheterization may be used to evaluate the extent of blood flow being pumped to the pulmonary circulation and to evaluate hemodynamic pressures.

Atrioventricular Canal Defect

Atrioventricular canal defect (atrioventricular septal defect [AVSD], AV canal, or endocardial cushion defect) accounts for 4% to 5% of congenital heart disease and occurs in 2 of every 10,000 live births. Forty percent of children with Down syndrome and CHD have this defect (Driscoll, 2006a).

Pathophysiology

AV canal defect occurs as a result of failure of the endocardial cushions to fuse (Fig. 40.6). These cushions are needed to separate the central parts of the heart near the tricuspid and mitral (AV) valves. The complete AV canal defect involves atrial and ventricular septal defects as well as a common AV orifice and a common AV valve. Partial and transitional forms of AV canal defect also occur, involving variations of the complete form.

The complete AV canal defect permits oxygenated blood from the lungs to enter the left atrium and ventricle, crossing over the atrial or ventricular septum and returning to the lungs via the pulmonary artery. This recirculation problem, which typically involves a left-to-right shunt, is inefficient because the left ventricle must pump blood back to the lungs and also meet the body's peripheral demand for oxygenated blood. Subsequently, the left ventricle must pump two to three times more blood than in a normal heart. Therefore, this specific type of cardiac defect causes a large left-to-right shunt; an increased workload of the left ventricle; and high pul-

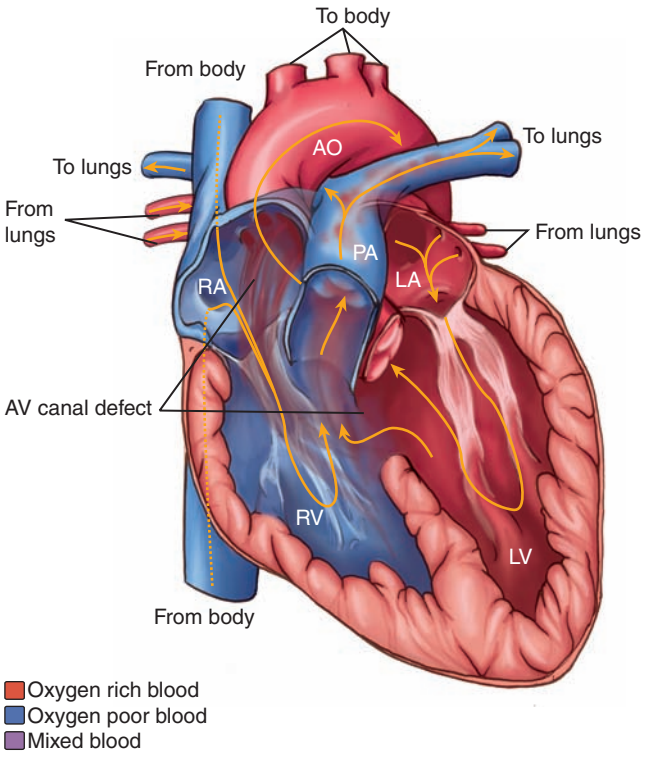

FIGURE 40.6 Atrioventricular canal defect.

monary arterial pressure, resulting in an increased amount of blood in the lungs and causing pulmonary edema (Driscoll, 2006a; Vick & Bezold, 2006).

Nursing Assessment

The infant with a complete AV canal defect commonly exhibits moderate to severe signs and symptoms of heart failure. However, for infants with partial or transitional AV canal defects, the signs and symptoms will be more subtle.

Health History and Physical Examination

Obtain the health history, noting frequent respiratory infections and difficulty gaining weight. Ask the parent if the infant has been experiencing difficulty feeding or increased work of breathing.

Inspect the skin, fingernails, and lips for cyanosis. Observe for retractions, tachypnea, and nasal flaring. Auscultate the lungs and heart, noting rales and a loud murmur. The murmur is commonly noted within the first 2 weeks of life. Infants with partial or transitional AV canal defect may display more subtle signs.

Laboratory and Diagnostic Tests

Echocardiography will reveal the extent of the defect and shunting as well as right ventricular hypertrophy. Electrocardiogram may indicate right ventricular hypertrophy and possible first-degree heart block due to impulse blocking before reaching the AV node.

Patent Ductus Arteriosus

PDA is failure of the ductus arteriosus, a fetal circulatory structure, to close within the first weeks of life (Fig. 40.7). As a result, there is a connection between the aorta and pulmonary artery. PDA is the second most common congenital heart defect and accounts for 10% of CHD cases (Mullins, 2006a). PDA occurs much more frequently in premature than in term infants: 45% of infants less than 1,750 g at birth and 80% of infants less than 1,200 g will display a PDA. PDA occurs 30 times more often in infants born at high altitudes compared with those born at sea level (Driscoll, 2006a). Infants with other congenital heart defects that result in right-to-left shunting of blood and cyanosis may additionally display a PDA. In these infants, the PDA allows for some level of oxygenated blood to reach the systemic circulation.

Pathophysiology

Failure of the ductus arteriosus to close leads to continued blood flow from the aorta to the pulmonary artery. Blood returning to the left atrium passes to the left ventricle, enters the aorta, and then travels to the pulmonary artery via the PDA instead of entering the systemic circulation. This altered blood flow pattern increases the workload of the left side of heart. Pulmonary vascular congestion occurs, causing an increase in pressure. Right ventricular pressure increases in an attempt to overcome this increase in pulmonary pressure. Eventually, right ventricular hypertrophy occurs.

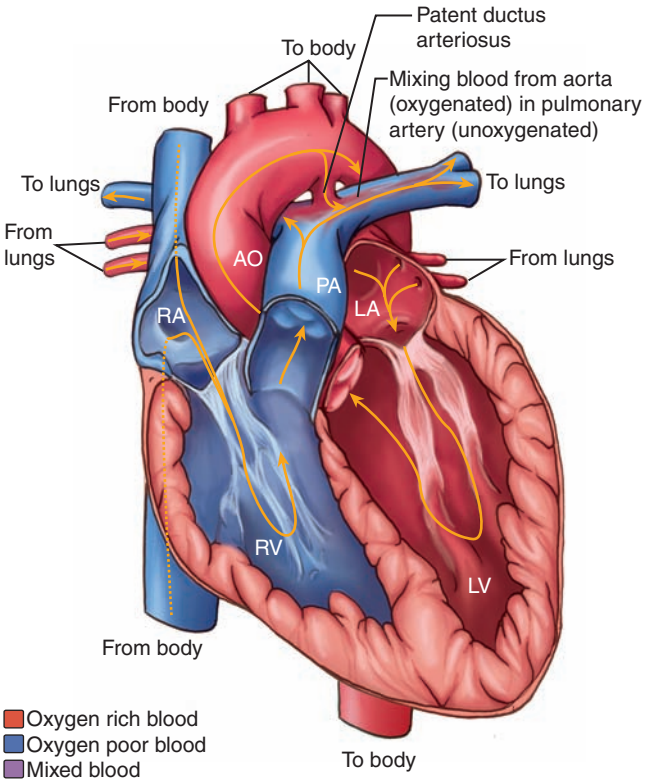

FIGURE 40.7 Patent ductus arteriosus.

Nursing Assessment

The symptoms of PDA depend on the size of the ductus arteriosus and the amount of blood flow it carries. If it is small, the infant may be asymptomatic. Some infants demonstrate signs and symptoms of heart failure.

Health History and Physical Examination

Determine the health history, which may reveal frequent respiratory infections, fatigue, and poor growth and development. On physical examination, note tachycardia, tachypnea, bounding peripheral pulses, and a widened pulse pressure. The diastolic blood pressure typically is low due to the shunting. Auscultate the lungs and heart, noting rales if heart failure is present. Note a harsh, continuous, machine-like murmur, usually loudest under the left clavicle at the first and second intercostal spaces.

Laboratory and Diagnostic Tests

Echocardiogram reveals the extent of the defective opening and confirms the diagnosis. Electrocardiogram may be normal or it may indicate ventricular hypertrophy, especially if the defect is large. Chest x-ray demonstrates cardiomegaly.

OBSTRUCTIVE DISORDERS

Another group of congenital heart defects is classified as obstructive disorders. These disorders involve some type of narrowing of a major vessel, interfering with the ability of the blood to flow freely through the vessel. As a result, peripheral circulation or blood flow to the lungs is affected. Increased pressure backing up toward the heart causes an increased workload on the heart. Examples of defects in this group include coarctation of the aorta, aortic stenosis, and pulmonic stenosis.

Coarctation of the Aorta

Coarctation of the aorta is narrowing of the aorta, the major blood vessel carrying highly oxygenated blood from the left ventricle of the heart to the rest of the body (Fig. 40.8). It is the third most common congenital heart defect. Coarctation occurs more than twice as often in males as in females (Morriss, 2006).

Pathophysiology

Coarctation of the aorta occurs most often in the area near the ductus arteriosus. The narrowing can be preductal (between the subclavian artery and ductus arteriosus) or postductal (after the ductus arteriosus). As a result of the narrowing, blood flow is impeded, causing pressure to increase in the area proximal to the defect and to decrease in the area distal to it. Thus, blood pressure is increased in the heart and upper portions of the body and decreased in the lower portions of the body. Left ventricular afterload is increased, and in some children this may lead to heart failure. Collateral circulation also may develop as the body attempts to ensure adequate blood flow to the descending aorta. Due to the elevation in blood pressure, the child is also at risk for aortic rupture, aortic aneurysm, and cerebrovascular accident (CVA).

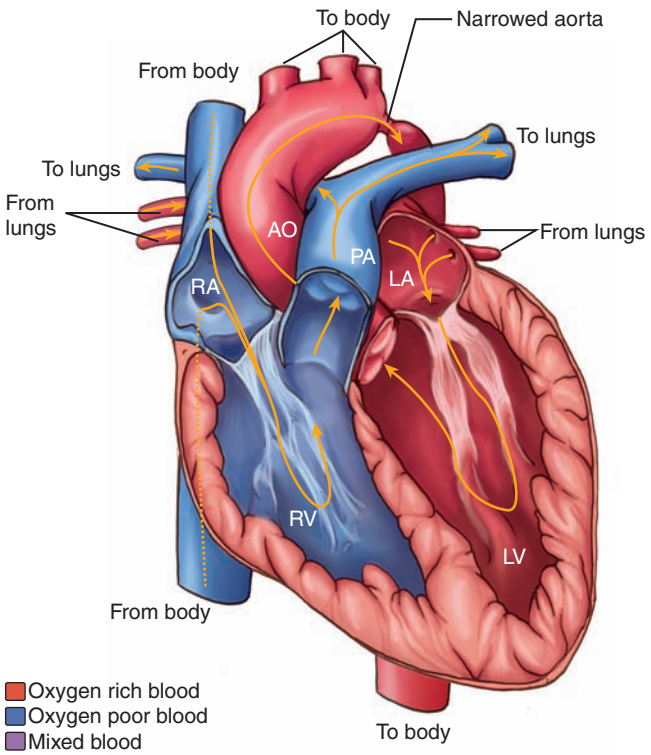

FIGURE 40.8 Coarctation of the aorta.

Nursing Assessment

The extent of the symptoms depends on the severity of the coarctation. Some children with coarctation of the aorta grow well into the school-age years before the defect is discovered.

Health History and Physical Examination

Determine the health history, noting problems with irritability and frequent epistaxis. In older children, there also may be reports of leg pain with activity, dizziness, fainting, and headaches. Assess pulses throughout, noting full, bounding pulses in the upper extremities with weak or absent pulses in the lower extremities. Determine BP in all four extremities. BP in the upper extremities may be 20 mm Hg or higher than that in the lower extremities. Inspect the school-age child's chest, noting notching of the ribs. Auscultate the heart for a soft or moderately loud systolic murmur, most often heard at the base of the heart.

Laboratory and Diagnostic Tests

Diagnosis of coarctation of the aorta is based primarily on the history and physical examination. In addition, an echocardiogram may disclose the extent of narrowing and evidence of collateral circulation. Chest x-ray may reveal left-sided cardiac enlargement and rib notching indicative of collateral arterial enlargement. Other tests, such as electrocardiogram, computed tomography, or MRI, may be done to provide additional evidence about the extent of the coarctation and subsequent effects.

Aortic Stenosis

Aortic stenosis is a condition causing obstruction of the blood flow between the left ventricle and the aorta. The occurrence of aortic stenosis is 4 per 1,000 live births, with 75% of cases occurring in males (Balentine & Eisenhart, 2005).

Pathophysiology

Aortic stenosis can be caused by a muscle obstruction below the aortic valve, an obstruction at the valve itself, or an aortic narrowing just above the valve (Fig. 40.9). The most common type is an obstruction of the valve itself, called aortic valve stenosis. The aortic valve consists of three very pliable leaflets. Normally the leaflets of the aortic valve spread open easily when the left ventricle ejects blood into the aorta. Aortic stenosis occurs when

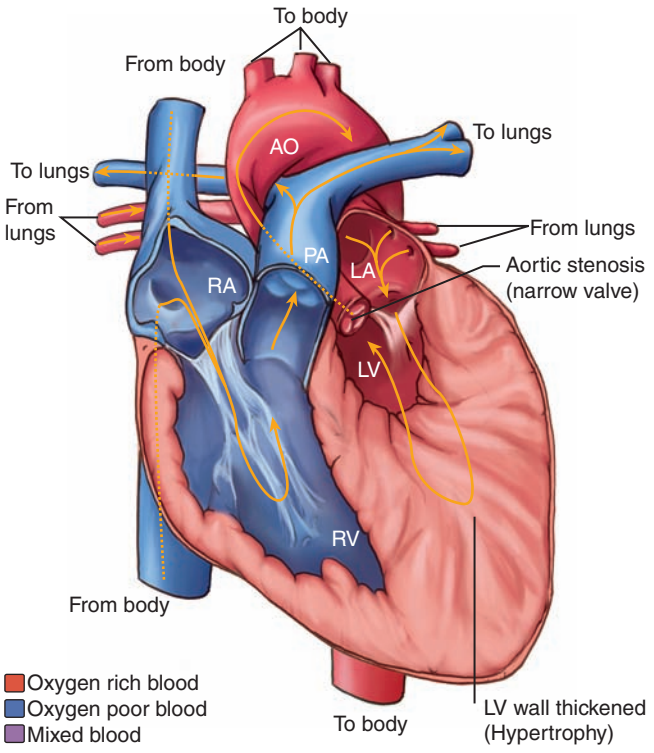

FIGURE 40.9 Aortic stenosis.

the aortic valve narrows, causing an obstruction between the left ventricle and the aorta. As a result, cardiac output decreases. When the aortic valve does not function properly, the left ventricle must work harder to pump blood into the aorta. Because of the increased workload, the left ventricular muscle hypertrophies. If this continues, left ventricular failure can occur, leading to a backup of pressure in the pulmonary circulation and pulmonary edema. Heart failure may occur, but this is more commonly seen in the infant (Driscoll, 2006a).

Nursing Assessment

Typically, the child with aortic stenosis is asymptomatic. However, it is important to obtain an accurate health history and perform a physical examination.

Health History and Physical Examination

Obtain the child's health history, noting easy fatigability or complaints of chest pain similar to anginal pain when active. Dizziness with prolonged standing also may be reported. In the infant, note difficulty with feeding. Palpate the child's pulse; if aortic stenosis is severe, the pulses may be faint. Palpate the child's chest, noting a thrill at the base of the heart. Auscultate the heart, noting a systolic murmur best heard along the left sternal border with radiation to the right upper sternal border.

Laboratory and Diagnostic Tests

The echocardiogram is the most important noninvasive test to identify aortic stenosis. An electrocardiogram may be normal in children with mild to moderate forms of aortic stenosis. For children with severe aortic stenosis, left ventricular hypertrophy may be determined from the electrocardiogram. For children experiencing easy fatigability and chest pain, an exercise stress test may be done to evaluate the degree of cardiac compromise.

Pulmonary Stenosis

Pulmonary stenosis is a condition that causes an obstruction in blood flow between the right ventricle and the pulmonary arteries. Pulmonary stenosis occurs in 7% to 12% of all cases of CHD (Cheatham, 2006). It is often associated with various genetic syndromes. Children may be asymptomatic, although some children with severe stenosis may exhibit dyspnea and fatigue with exertion (demonstrating hypercyanotic spells similar to those in children with tetralogy of Fallot).

Pathophysiology

Pulmonary stenosis may occur as a muscular obstruction below the pulmonary valve, an obstruction at the valve, or a narrowing of the pulmonary artery above the valve (Fig. 40.10). Valve obstruction is the most common form of pulmonary stenosis. Normally the pulmonary valve is constructed with three thin and pliable valve leaflets; they spread apart easily, allowing the right ventricle to eject blood freely into the pulmonary artery. The most common problem causing pulmonary stenosis is that the pul-

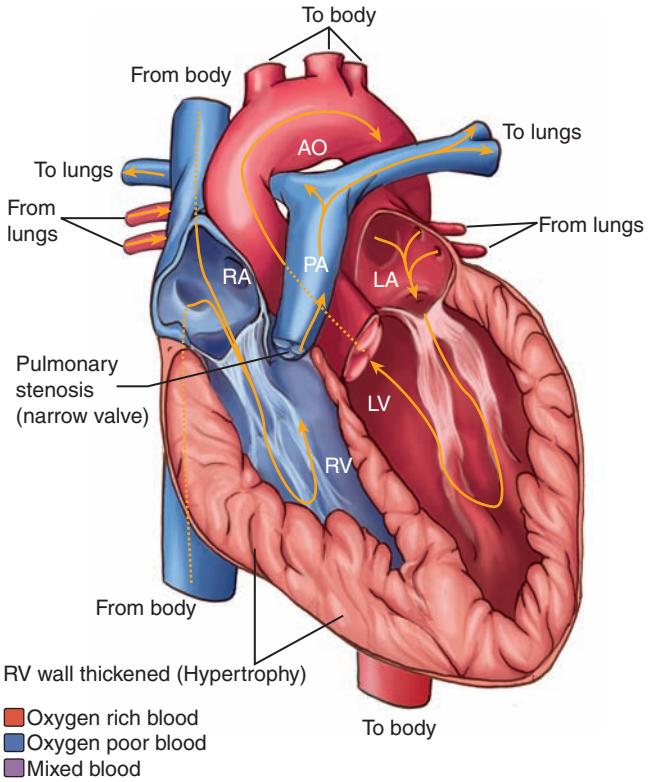

FIGURE 40.10 Pulmonary stenosis.

monary valve leaflets are thickened and fused together along their separation lines, causing the obstruction to blood flow. The right ventricle has an additional workload, causing the muscle to thicken, resulting in right ventricular hypertrophy and decreased pulmonary blood flow. When the pulmonary valve is severely obstructed, the right ventricle cannot eject sufficient blood into the pulmonary artery. As a result, pressure in the right atrium increases, which could lead to a reopening of the foramen ovale. If this occurs, deoxygenated blood would pass through the foramen ovale into the left side of the heart and would then be pumped to the systemic circulation. In some cases, a PDA may be present, thus allowing for some compensation by shunting blood from the aorta to the pulmonary circulation for oxygenation.

Nursing Assessment

The child with pulmonary stenosis may be asymptomatic or may exhibit signs and symptoms of mild heart failure. If the stenosis is severe, the child may demonstrate cyanosis. Therefore, it is important for the nurse to obtain an accurate health history and physical examination.

Health History and Physical Examination

Elicit the health history, noting mild dyspnea or cyanosis with exertion. Document the child's growth history, which is typically normal. Carefully palpate the sternal border for a thrill (not always present). Auscultate the heart, noting a high-pitched click following the second heart sound and a systolic ejection murmur loudest at the upper left sternal border.

Laboratory and Diagnostic Tests

An echocardiogram reveals the extent of obstruction present at the valve, as well as right ventricular hypertrophy. An electrocardiogram also helps to detect right ventricular hypertrophy.

MIXED DEFECTS

Mixed defects are congenital heart defects that involve a mixing of well-oxygenated blood with poorly oxygenated blood. As a result, systemic blood flow contains a lower oxygen content. Cardiac output is decreased, and heart failure occurs. Examples of mixed defects include transposition of the great vessels, total anomalous pulmonary venous connection, truncus arteriosus, and hypoplastic left heart syndrome.

Transposition of the Great Vessels (Arteries)

Transposition of the great vessels (TGV) is a congenital heart defect in which the pulmonary artery and the aorta arise from the ventricle opposite that from which they normally arise. Thus, the vessels are transposed from their normal positions. The aorta arises from the right ventricle instead of the left ventricle and the pulmonary artery arises from the left ventricle instead of the right ventricle. Transposition of the great vessels accounts for approximately 5% of all CHD cases. It is most often diagnosed in the first few days of life when the child manifests cyanosis, which indicates decreased oxygenation. As the ductus arteriosus closes, the symptoms will worsen. Heart failure may also be present in the first weeks to months of life. If untreated, 50% of affected infants will die in the first month of life and 90% in the first year.

Pathophysiology

In TGV there is no connection or communication between the pulmonary and systemic circulations (Fig. 40.11). TGV creates a situation in which poorly oxygenated blood returning to the right atrium and ventricle is then pumped out to the aorta and back to the body. Oxygenated blood returning from the lungs to the left atrium and ventricle is then sent back to the lungs through the pulmonary artery. Unless there is a connection somewhere in the circulation where the oxygen-rich and oxygen-poor blood can mix, all the organs of the body will be poorly oxygenated. Often the ductus arteriosus remains patent, allowing for some mixing of blood. Similarly, if a VSD is also present, mixing of blood may occur and cyanosis will be delayed. However, these associated defects can lead to increased pulmonary blood

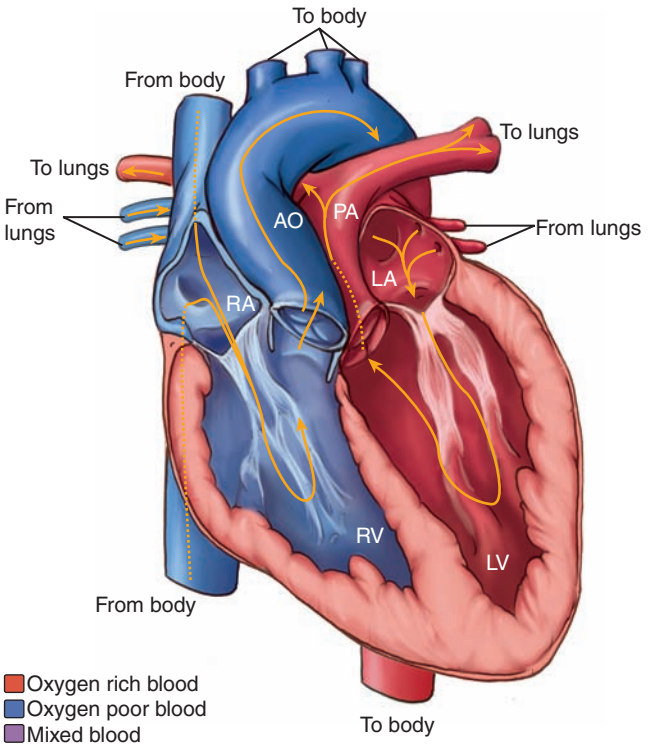

FIGURE 40.11 Transposition of the great vessels.

flow that increases pressure in the pulmonary circulation. This predisposes the child to heart failure.

Nursing Assessment

Significant cyanosis without a murmur in the newborn period is highly indicative of TGV. In about 10% of infants, cyanosis will not develop until several days of age as the PDA closes (Molczan, 2006). In infants with septal defects, cyanosis may be further delayed.

Health History and Physical Examination

Elicit the health history, noting onset of cyanosis with feeding or crying. Observe the infant for cyanosis while active and at rest. Observe the chest, noting a prominent ventricular impulse. Auscultate the heart, noting a loud second heart sound. A murmur may be heard if the ductus remains open or a septal defect is present. If heart failure is present, note edema, tachypnea, and adventitious lung sounds.

Laboratory and Diagnostic Tests

Echocardiography clearly reveals evidence of the transposition. Cardiac catheterization may be performed, determining low oxygen saturation levels due to the mixing of the blood.

Total Anomalous Pulmonary Venous Connection

Total anomalous pulmonary venous connection (TAPVC) is a rare congenital heart defect in which the pulmonary veins do not connect normally to the left atrium; instead, they connect to the right atrium, often by way of the superior vena cava. Males exhibit this disorder three times more often than females (Ward, 2006).

Pathophysiology

Oxygenated blood that would normally enter the left atrium now enters the right atrium and passes to the right ventricle. As a result, the pressure on the right side of the heart increases, leading to hypertrophy. TAPVC is incompatible with life unless there is an associated defect present that allows for shunting of blood from the highly pressured right side of the heart. A patent foramen ovale or an ASD is usually present. Since none of the pulmonary veins connect normally to the left atrium, the only source of blood to the left atrium is blood that is shunted from the right atrium across the defect to the left side of the heart (Fig. 40.12). The highly oxygenated blood from the lungs completely mixes with the poorly oxygenated blood returning from the systemic circulation. This causes an overload of the right atrium and right ventricle. The increased blood volume going into the lungs can lead to pulmonary hypertension and pulmonary edema.

Nursing Assessment

The degree of cyanosis present with TAPVC depends on the extent of the associated defects. For example, if the foramen ovale closes or the ASD is small, significant cyanosis will be present. The physical examination findings will vary depending on the type of TAPVC the infant has, whether obstruction is present, and which other associated cardiac anomalies are present.

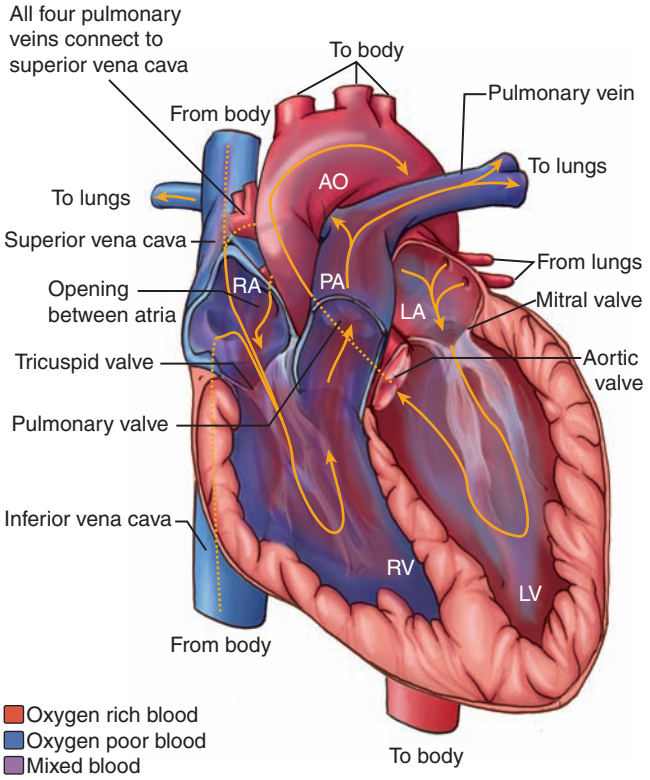

FIGURE 40.12 Total anomalous pulmonary venous connection.

Health History and Physical Examination

Note history of cyanosis, tiring easily, and difficulty feeding. Observe the chest for prominence of the right ventricular impulse and retractions with tachypnea. Auscultate the heart, noting fixed splitting of the second heart sound and a murmur. Palpate the abdomen for hepatomegaly.

Laboratory and Diagnostic Tests

An echocardiogram will reveal the abnormal connection of the pulmonary veins, enlargement of the right atrium and right ventricle, and an ASD if present. The chest x-ray will demonstrate an enlarged heart and pulmonary edema. Cardiac catheterization can also be useful to visualize the abnormal connection of the pulmonary veins, particularly if an obstruction is present.

Truncus Arteriosus

Truncus arteriosus is a congenital heart defect in which only one major artery leaves the heart and supplies blood to the pulmonary and systemic circulations. It affects males and females equally and accounts for 1% to 4% of all CHD cases (Slesnick & Kovalchin, 2006). A VSD may also be present.

Pathophysiology

The one great vessel contains one valve which comprises two to five leaflets and is positioned over both the left and right ventricles (Fig. 40.13). Due to the location, blood from the left ventricle mixes with blood from the right ventricle. Pressure in the pulmonary circulation typically is less than that of the systemic circulation, leading to increased blood flow to the lungs. As a result, systemic blood flow is decreased. Over time, the increased pulmonary blood flow can lead to pulmonary vascular disease.

Nursing Assessment

Typically, the infant demonstrates cyanosis in varying degrees depending on the extent of compromise in the systemic circulation. Obtain an accurate health history and perform a physical examination.

Health History and Physical Examination

Elicit the health history, noting history of cyanosis that increases with periods of activity such as feeding. Also note history of tiring easily, difficulty in feeding, and poor growth. Count the respiratory rate, which may be elevated. Observe for nasal flaring, grunting or noisy breathing, retractions, and restlessness. Auscultate the lungs, noting adventitious breath sounds, and the heart, noting a murmur associated with a VSD.

Laboratory and Diagnostic Tests

An echocardiogram will confirm the presence of truncus arteriosus as the anatomy of the great vessels, the single truncal valve, and the VSD will be seen. On rare occasions a cardiac catheterization may be done to determine pressures in the pulmonary arteries.

Hypoplastic Left Heart Syndrome

Hypoplastic left heart syndrome (HLHS) is a congenital heart defect in which all of the structures on the left side of the heart are severely underdeveloped (Fig. 40.14). The mitral and aortic valves are completely closed or very small. The left ventricle is nonfunctional. Thus, the left side of the heart is completely unable to supply blood to the systemic circulation. HLHS is the fourth most common congenital heart defect. It appears to have a multifactorial and autosomal recessive inheritance pattern. Almost 30% of infants with HLHS also have a definable genetic or other congenital anomaly in addition to the heart defect (Eidem, 2006). The options for treatment include palliative care, cardiac transplantation within the first few weeks of life, or palliative reconstructive surgery consisting of three stages, beginning within days to weeks of birth (Kilian, 2006).

Pathophysiology

With HLHS, the right side of the heart is the main working part of the heart. Blood returning from the lungs into the left atrium must pass through an ASD to the right side of the heart. The right ventricle must then pump blood to the lungs and also to the systemic circulation through the PDA. A few days after birth, when the ductus arteriosus

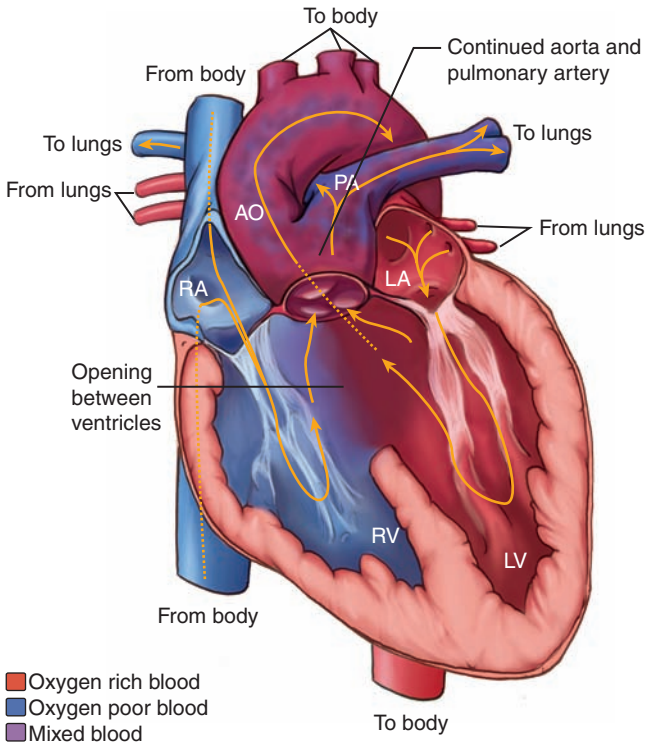

Figure 40.13 Truncus arteriosus.

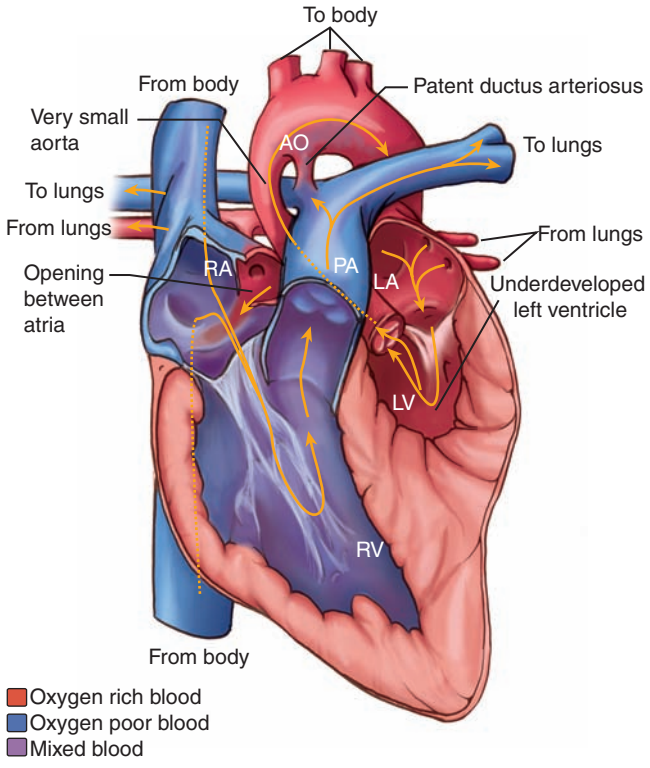

Figure 40.14 Hypoplastic left heart syndrome.

closes, the heart cannot pump blood into the systemic circulation, causing poor perfusion of the vital organs and shock. Death will occur rapidly without intervention.

Nursing Assessment

Initially after birth, the newborn may be asymptomatic because the ductus arteriosus is still patent. However, as the ductus begins to close at a few days of age, the newborn will begin to exhibit cyanosis. Some infants may present with circulatory collapse (shock) and must be resuscitated emergently.

Health History and Physical Examination

Obtain the health history, noting onset of cyanosis. Note poor feeding and history of tiring easily. Evaluate the vital signs, noting tachycardia, tachypnea, and hypothermia. Observe for increased work of breathing and gradually increasing cyanosis. Note pallor of the extremities and decreased oxygen saturation via pulse oximetry. Auscultate the heart and lungs. Note adventitious breath sounds, gallop rhythm, single second heart sound, and a soft systolic ejection or holosystolic murmur.

Laboratory and Diagnostic Tests

Prenatally, a fetal echocardiogram can diagnose this syndrome, as can a maternal ultrasound. After birth, the echocardiogram illustrates the defect.

NURSING MANAGEMENT OF THE CHILD WITH CONGENITAL HEART DISEASE

The child with a congenital heart defect has multiple needs and requires comprehensive, multidisciplinary care. Nurses play a key role in helping the child and family during this intensely stressful time. Nursing care focuses on improving oxygenation, promoting adequate nutrition, assisting the child and family with coping, providing postoperative nursing care, preventing infection, and providing patient and family education. An important component of education involves preparing the child and parents for discharge. In addition to the nursing management presented below, refer to Nursing Care Plan 40.1 for additional interventions appropriate for the child with CHD. Individualize nursing care specific to the child's needs.

Improving Oxygenation

Due to the hemodynamic changes accompanying the underlying structural defect, oxygenation is key. Provide frequent ongoing assessment of the child's cardiopulmonary status. Assess airway patency and suction as needed. Position the child in Fowler's or semi-Fowler's position to facilitate lung expansion. Monitor vital signs, especially heart and respiratory rates. Monitor the child's color and oxygen saturation levels closely, using these to guide oxygen administration. Observe for tachypnea and other signs of respiratory distress, such as nasal flaring, grunting, and retractions. Auscultate the lungs for adventitious sounds. Provide humidified supplemental oxygen as ordered, warming it to prevent wide temperature fluctuations. Anticipate the need for assisted ventilation if the child has difficulty maintaining the airway or experiences deterioration in oxygenation capacity. Box 40.1 lists interventions related to relief of hypercyanotic spells.

Promoting Adequate Nutrition

Adequate nutrition is critical to foster growth and development as well as to reduce the risk for infection. Children with congenital heart defects typically have increased nutritional needs due to the increased energy expenditure associated with increased cardiac and respiratory workloads. In addition, many of the defects lead to heart failure, which may affect the child's fluid balance status, further increasing the child's energy expenditure.

Nutrition may be provided orally, enterally, or parenterally. For example, for the newborn or infant, nutrition via breast milk or formula may be provided orally or via gavage feedings. Breastfeeding is usually associated with decreased energy expenditure during the act of feeding, yet some infants in intensive care are not stable enough to breastfeed. Gavage with breast milk is possible, and the use of human milk fortifier (either with breastfeeding or added to the gavage feed) adds additional calories that the infant requires. Formula-fed infants may also require increased-calorie formula, which may be achieved by more concentrated mixing of the formula or through the use of additives such as Polycose or vegetable oil. Consult the nutritionist to determine the individual infant's caloric needs and prescription of appropriate feeding.

Cutting a large hole in the nipple or "cross-cutting" the nipple decreases the work of feeding for some infants. Generally, nipple feedings should be limited to a 20-minute duration, as feeding for longer periods results in excess caloric expenditure. Many infants may feed orally for 20 minutes, receiving the remainder of that feeding via orogastric or nasogastric tube. Offer older children small, frequent feedings to reduce the amount of energy required

BOX 40.1 Relieving Hypercyanotic Spells

- Use a calm, comforting approach.
- Place the infant or child in a knee-to-chest position.
- Provide supplemental oxygen.
- Administer morphine sulfate (0.1 mg/kg IV, IM, or SQ).
- Supply IV fluids.
- Administer propranolol (0.1 mg/kg IV).

to feed or eat and to prevent overtiring the child. When needed, administer and monitor total parenteral nutrition as prescribed.

▶ *Take* NOTE!

Breastfeeding a child before and after cardiac surgery may boost the infant's immune system, which can help fight postoperative infection. If breastfeeding is not possible, mothers can pump milk and the breast milk may be given via bottle, dropper, or gavage feeding.

Assisting the Child and Family to Cope

The diagnosis of CHD is especially overwhelming for the child and the parents. The numerous examinations, diagnostic tests, and procedures are sources of stress for the infant or child regardless of age and for the parents. The parents may fear long-term disability or death or may worry that allowing the child to engage in any activity will worsen his or her status. Thus, the parents may tend to overprotect the child. It is important for the parents to continue parenting the child, even when the child requires extended hospitalizations or intensive care (Fernandes, 2005). Explain all that is happening with the child, using language the parents and child can understand. Allow the parents and child to voice their feelings, concerns, or questions. Provide ample time to address these questions and concerns. Encourage the parents, and the child as developmentally appropriate, to participate in the child's care.

If the child is a newborn or infant, encourage attachment and bonding. Emphasize the child's positive attributes, including the normal aspects of the infant. Help the parents to experience the joy of a new infant, seeing the beauty of the child, no matter how ill the infant is (Fernandes, 2005). Urge the parents to touch, stroke, pat, and talk to the infant. Encourage them to hold the infant close, using kangaroo care as appropriate. If the child is older, offer suggestions as to how the parents can meet the child's emotional needs. For example, encourage them to bring a favorite toy or object from home while the child is hospitalized.

Provide developmentally appropriate explanations to the child. Encourage play therapy to help the child understand what is happening.

Preventing Infection

Teach parents proper hand hygiene. Provide appropriate dental care. Make sure the child receives prophylaxis for infective endocarditis as needed. Ensure that children 24 months or younger who have hemodynamically significant heart defects receive respiratory syncytial virus (RSV) prophylaxis as recommended during RSV season (Ressel, 2004).

Providing Care for the Child Undergoing Cardiac Surgery

Cardiac surgery may be necessary to correct a congenital defect or to provide symptomatic relief. The surgery may be planned as an elective procedure or done as an emergency. Open-heart surgery involves an incision of the heart muscle to repair the internal structures. This may require cardiopulmonary bypass. Closed-heart surgery involves structures related to the heart but not the heart muscle itself and may be performed with or without cardiopulmonary bypass (Kopf & Mello, 2006; Muscari, 2004).

Providing Preoperative Care

The preoperative nursing assessment complements the history and physical examination and provides important baseline information for comparison during the postoperative period. Establish a relationship with the child and parents. Identify problems that may require particular nursing interventions during the postoperative period. Before cardiac surgery, interview the parents and, if age-appropriate, the child. Focus the interview on the history of the present illness, cardiac risk factors, the child's present physical and functional status, additional medical problems, current medications and drug allergies, the child's and family's understanding of the illness and planned procedure, and the family support system.

The preoperative physical assessment includes:

- Temperature and weight measurements
- Examination of extremities for peripheral edema, clubbing, and evaluation of peripheral pulses
- Auscultation of the heart (rate, rhythm, heart sounds, murmurs, clicks, and rubs)
- Respiratory assessment, including respiratory rate, work of breathing, and auscultation of the lungs for breath sounds

Obtain any necessary laboratory and diagnostic tests to establish a baseline. In addition, review the results of any tests done previously. Testing may include CBC, electrolyte levels, clotting studies, urinalysis, cultures of blood and other body secretions, renal and hepatic function tests, chest x-ray, electrocardiogram, echocardiogram, and cardiac catheterization.

In most nonemergent cases, preoperative assessment is performed in an outpatient setting and the patient is admitted to the hospital on the day of surgery. Nursing care during this phase focuses on thorough patient and parent education. If the surgery is an emergency, patient teaching must be done quickly, emphasizing the most important elements of the child's care.

Child and parent education typically includes the following topics:

- Heart anatomy and its function, including what area is involved with the defect that is to be corrected
- Events before surgery, including any testing or preparation such as a skin scrub
- Location of the child after surgery, such as a pediatric intensive care unit, which may include a visit to the unit if appropriate and explanation of the sights and sounds that may be present
- Appearance of the child after surgery (equipment or devices used for monitoring, such as oxygen administration, electrocardiogram leads, pulse oximeter, chest tubes, mechanical ventilation, or intravenous lines)
- Approximate location of the incision and coverage with dressings
- Postoperative activity level, including measures to reduce the risk of complications, such as coughing and deep-breathing exercises, incentive spirometry, early ambulation, and leg exercises
- Nutritional restrictions, such as nothing by mouth for a specified time before surgery and use of intravenous fluids
- Medications, such as anesthesia, sedation, and analgesics as well as medications the child is taking now that need to be continued or withheld

Prepare and educate the child at an age- and developmentally appropriate level. Advise parents to read books with their child about CHD and hospitalization such as:

- "Clifford Visits the Hospital" by N. Bridwell, 2000 (Scholastic Inc.)
- "Franklin Goes to the Hospital" by P. Bourgeois, 2000 (Scholastic Paperbacks)
- "Pump the Bear" by G. O. Whittingon, 2000 (Brown Books)
- "Blue Lewis and Sasha the Great" by C. D. Newell, 2005 (Cally Press)
- "Cardiac Kids: A Book for Families Who Have a Child with Heart Disease" by V. Elder, 1994 (Dayton Area Heart and Cancer Association)
- "When Molly Was in the Hospital: A Book for Brothers and Sisters of Hospitalized Children" by D. Duncan, 1994 (Rayve Productions) (siblings)
- "A Night Without Stars" by J. Howe, 1993 (Camelot) (older children)

Additionally, parents may order "It's My Heart", a parent resource book, free of charge from the Children's Heart Foundation at http://www.childrensheartfoundation.org/its_my_heart.htm.

Parents may also help their child by buying a small thrift-store suitcase, spray-painting it, and allowing the child to decorate it with his or her name, pictures of family, stickers, or favorite story characters. This will be the child's "hospital suitcase" that the child may pack with toys and videos to bring to the hospital. Hospital tours are appropriate for school-age children, and older children and teens may benefit from an intensive care unit tour before surgery.

Instruct parents to stop food and liquids at the designated time, depending on the child's age, and to give all medications as directed. Some medications may be withheld before surgery. If the child's nutritional status is poor or questionable, nutritional supplementation may be ordered for a period of time preoperatively to ensure that the child has the best possible nutritional status before surgery. When it is time for the child to be transported to the surgical area, allow the parents to accompany the child as far as possible, depending on the institution's policy. Also reinforce with the child that the parents will be present at the bedside when he or she awakens from surgery.

Providing Postoperative Care

The child will usually be transported from the operating room to the intensive care unit. Depending on the age, postoperative stability, and type of surgery, the child may stay in the intensive care unit for several hours up to several days. Vigilant nursing care aids in the transition of the child and parents after surgery and reduces the risk of complications.

During the postoperative period the nurse should do the following:

- Assess vital signs frequently, as often as every 1 hour, until stable.
- Assess the color of the skin and mucous membranes, check capillary refill, and palpate peripheral pulses.
- Observe cardiac rate and rhythm via electronic monitoring and auscultate heart rate, rhythm, and sounds frequently.
- Monitor hemodynamic status via arterial and/or central venous lines (left and right atrial, and pulmonary artery pressures, pulmonary artery oxygen saturation).
- Provide site care and tubing changes according to the institution's policy.
- Auscultate lungs for adventitious, diminished, or absent breath sounds.
- Assess oxygen saturation levels via pulse oximetry and arterial blood gases as well as work of breathing and level of consciousness frequently.
- Administer supplemental oxygen as needed.
- Monitor mechanical ventilation and suction as ordered.
- Inspect chest tube functioning, noting amount, color, and character of drainage.
- Inspect the dressing (incision and chest tube) for drainage and intactness. Reinforce or change the dressing as ordered.
- Assess the incision for redness, irritation, drainage, or separation.
- Monitor intake and output hourly.
- Maintain accurate intravenous infusion rate; restrict fluids as ordered to prevent hypervolemia.

- Assess for changes in level of consciousness. Report restlessness, irritability, or seizures.
- Obtain ordered laboratory tests, such as CBC, coagulation studies, cardiac enzyme levels, and electrolyte levels. Report abnormal results.
- Administer medications, such as digoxin or inotropic or vasopressor agents, as ordered, watching the child closely for possible adverse effects.
- Encourage the child to turn, cough, deep breathe, use the incentive spirometer, and splint the incisional area with pillows.
- Assess the child's pain level and administer analgesics as ordered. Allow time for the child to rest and sleep.
- Assist the child to get out of bed as soon as possible and as ordered.
- Assess daily weights.
- Administer small, frequent feedings or meals when oral intake is allowed.
- Position the child in a comfortable position, one that maximizes chest expansion. Change position frequently.
- Assess the child for complications (Box 40.2).
- Provide emotional and physical support to the child and family, making appropriate referrals such as to social services for assistance.
- Prepare the patient and family for discharge (Beke et al., 2005).

▶ *Take* NOTE!

Abrupt cessation of chest tube output accompanied by an increase in heart rate and increased filling pressure (right atrial) may indicate cardiac tamponade (Beke et al., 2005).

BOX 40.2 Possible Complications After Cardiac Surgery

- Atelectasis
- Bacterial endocarditis
- Cardiac arrhythmias
- Cardiac tamponade
- Cerebrovascular accident
- Heart failure
- Hemorrhage
- Pleural effusion
- Pneumonia
- Pneumothorax
- Postperfusion syndrome
- Postcardiac surgery syndrome
- Pulmonary edema
- Seizures
- Wound infection

Providing Patient and Family Education

Provide patient and family education throughout the child's stay. Initially, teaching focuses on the underlying defect and measures to treat or control the problem. If the child requires surgery, teaching shifts to preoperative and postoperative events. Emphasize discharge teaching for each admission. Teaching Guidelines 40.2 highlights the major areas to be addressed in patient and family education.

Acquired Cardiovascular Disorders

Acquired cardiovascular disorders occur in children as a result of an underlying cardiovascular problem or may refer to other cardiac disorders that are not congenital. The most common type of acquired cardiovascular disorder in children is heart failure. Other acquired disorders include rheumatic fever, cardiomyopathy, infective endocarditis, hyperlipidemia, hypertension, and Kawasaki disease.

TEACHING GUIDELINES 40.2

Caring for the Child With a Congenital Heart Disease

- Give medications, if ordered, exactly as prescribed.
- Weigh the child at least once a week or as ordered, at approximately the same time of the day with the same scale, and wearing the same amount of clothing.
- Allow the child to engage in activity as directed. Provide time for the child to rest frequently throughout the day to prevent overexertion.
- Provide a nutritious diet, taking into account any restrictions for fluids or foods.
- Use measures to prevent infection, such as frequent handwashing, prophylactic antibiotics, and skin care.
- Adhere to schedule for follow-up diagnostic tests and procedures.
- Support the child's growth and development needs.
- Use available community support services.
- Notify the primary care provider if the child has increasing episodes of respiratory distress, cyanosis, or difficulty breathing; fever; increased edema of the hands, feet, or face; decreased urinary output; weight loss or difficulty eating or drinking; increased fatigue or irritability; decreased level of alertness; or vomiting or diarrhea.

HEART FAILURE

Heart failure occurs most often in children with CHD and is the most common reason for admission to the hospital for children with CHD. Eighty percent of all cases of heart failure in children with CHD occur by the age of 1 year (Freitas-Nichols, 2004). Heart failure also occurs secondary to other conditions such as myocardial dysfunction following surgical intervention for CHD, cardiomyopathy, myocarditis, fluid volume overload, hypertension, anemia, or sepsis or as a toxic effect of certain chemotherapeutic agents used in the treatment of cancer. Heart failure refers to a set of clinical signs and symptoms that reflect the heart's inability to pump effectively to provide adequate blood, oxygen, and nutrients to the body organs and tissues.

The child experiencing heart failure requires a multidisciplinary approach to care. Collaboration is necessary to achieve improved cardiac function, restored fluid balance, decreased cardiac workload, and improved oxygen delivery to the tissues.

Pathophysiology

Cardiac output is controlled by preload (diastolic volume), afterload (ventricular wall tension), myocardial contractility (inotropic state), and heart rate. Protracted alterations in any of these factors may lead to heart failure. In the event of reduced cardiac output, multiple compensatory mechanisms are activated. When the ventricular contraction is impaired (systolic dysfunction), reduced ejection of blood occurs, and therefore cardiac output is reduced. Diminished ability to receive venous return (diastolic dysfunction) occurs when high venous pressures are required to support ventricular function. As a result of decreased cardiac output, the renin-angiotensin-aldosterone system is activated as a compensatory mechanism. Fluid and sodium retention as well as improved contractility and vasoconstriction then occur. Initially blood pressure is supported and organ perfusion is maintained, but increased afterload worsens systolic dysfunction. As the heart chambers dilate, myocardial oxygen consumption increases and cardiac output is limited by excessive wall stretch. Over time, the capacity of the heart to respond to these compensatory mechanisms fails, and cardiac output is further decreased (Francis et al., 2008). Figure 40.15 shows the clinical manifestations that occur related to the mechanisms of heart failure.

Therapeutic Management

Management of heart failure is supportive. Promotion of oxygenation and ventilation is of utmost importance. Digitalis, diuretics, inotropic agents, vasodilators, antiarrhythmics, and antithrombotics have been widely used in children for palliation of symptoms (Rosenthal et al., 2004). Many children with heart failure require management in the intensive care unit until they are stabilized. Augmenting nutrition and ensuring adequate rest are also key components of management.

Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1285. Specific assessment findings related to heart failure are discussed below.

Health History

When obtaining the health history, elicit a description of the present illness and chief complaint. Common complaints reported during the health history might include:

- Failure to gain weight or rapid weight gain
- Failure to thrive
- Difficulty feeding
- Fatigue
- Dizziness, irritability
- Exercise intolerance
- Shortness of breath
- Sucking and then tiring quickly
- Syncope
- Decreased number of wet diapers

Infants with heart failure often display subtle signs such as difficulty feeding and tiring easily. Pay close attention for reports of these problems from the parents. Also be alert for statements such as "the baby drinks a small amount of breast milk (or formula) and stops, but then wants to eat again very soon afterwards"; "the baby seems to perspire a lot during feedings"; or "the baby seems to be more comfortable when he's sitting up or on my shoulder than when he's lying flat." In addition, the parents may report episodes of rapid breathing and grunting.

The child's current and past medical history also provides additional clues. Question the parents about any history of congenital heart defects and treatments such as surgery to repair the defect. Determine the current medication regimen. Also ask about any recent or past infections, such as streptococcal infections or fever.

Physical Examination

Weigh the child and note recent rapid weight gain or lack of weight gain. Obtain the child's vital signs, noting tachycardia or tachypnea. These findings are often the first indicators of heart failure in an infant or older child. Measure the BP in the upper and lower extremities, comparing the findings for differences. Note decreased BP, which may be due to impaired cardiac muscle function. Inspect the skin color, noting pallor or cyanosis. Also observe for diaphoresis (profuse sweating). Inspect the face, hands, and lower extremities for edema. Observe for increased work of breathing, such as nasal flaring or retractions. Note the presence of a cough, which may be productive with bloody

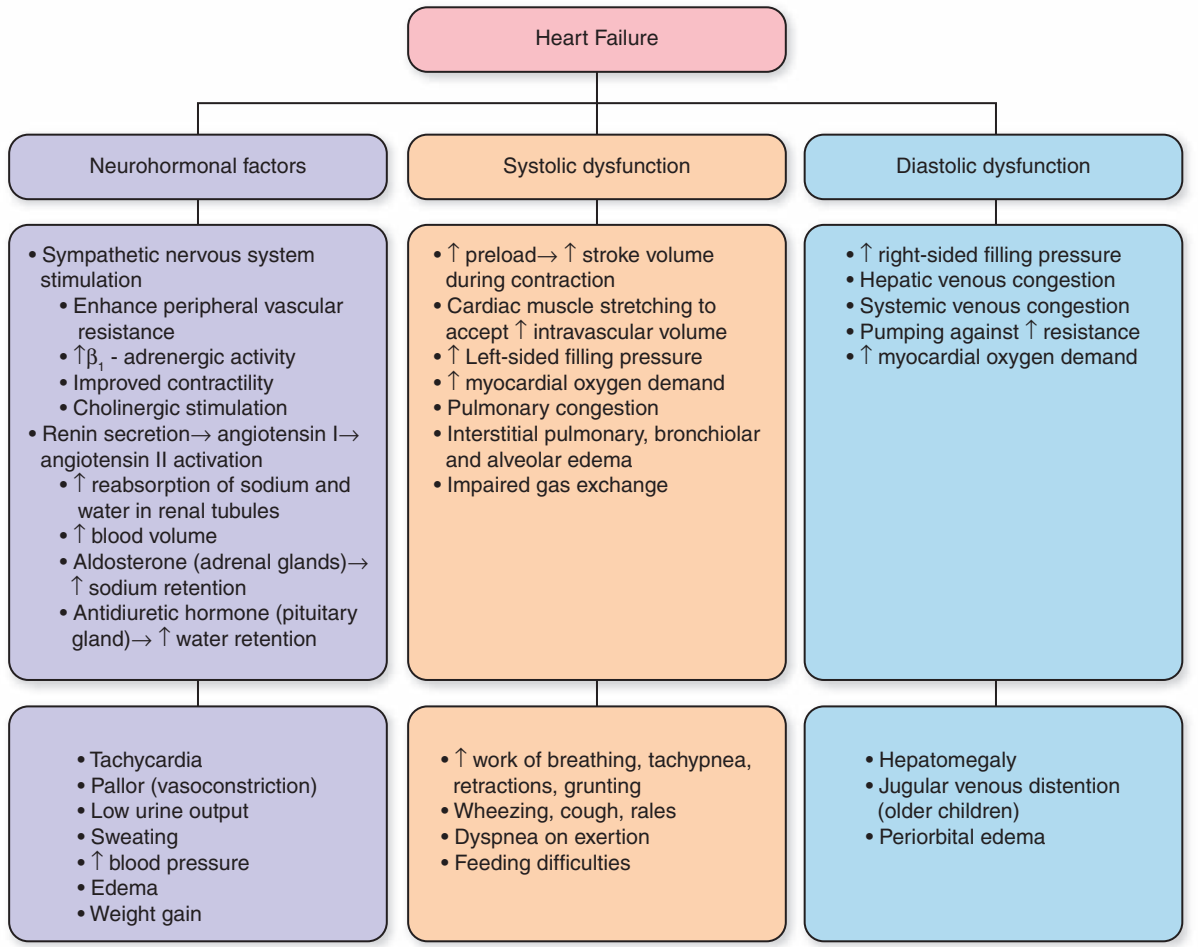

FIGURE 40.15 Pathophysiology of heart failure. (From Francis et al., 2008).

sputum. Auscultate the apical pulse, noting its location and character. Listen for a murmur, which may suggest a congenital heart defect, a gallop rhythm, or an accentuated third heart sound, suggesting sudden ventricular distention. Auscultate the lungs, noting crackles or wheezes suggestive of pulmonary congestion. Palpate the peripheral pulses, noting weak or thready pulses. Note the temperature and color of the extremities; they may be cool, clammy, and pale.

Assess the child's abdomen, looking for distention indicative of ascites. Gently palpate the abdomen to identify hepatomegaly or splenomegaly.

Laboratory and Diagnostic Tests

The diagnosis of heart failure is based on the child's signs and symptoms and is confirmed with several laboratory and diagnostic tests. These include:

- Chest x-ray, revealing an enlarged heart and/or pulmonary edema
- Electrocardiogram, indicating ventricular hypertrophy
- Echocardiogram, revealing the underlying cause of heart failure, such as a congenital heart defect

Other tests may be done to support the diagnosis. For example, the CBC may show evidence of anemia or infection. Electrolyte levels may reveal hyponatremia secondary to fluid retention and hyperkalemia secondary to tissue destruction or impaired renal function. Arterial blood gas results may demonstrate respiratory alkalosis in mild heart failure or metabolic acidosis. Tissue hypoxia may be evidenced by increased lactic acid and decreased bicarbonate levels.

Nursing Management

Nursing management of the child with heart failure focuses on promoting oxygenation, supporting cardiac function, providing adequate nutrition, and promoting rest.

Promoting Oxygenation

Position the infant or child in a semi-upright position to decrease work of breathing and lessen pulmonary congestion. Suction as needed. Chest physiotherapy and postural drainage may also be beneficial. Administer supplemental oxygen as ordered and monitor oxygen saturation via pulse oximetry. Oxygen also serves the function of vasodilator

and decreases pulmonary vascular resistance. Occasionally, the infant or child with heart failure may require intubation and positive-pressure ventilation to normalize blood gas tension.

▶ *Take* NOTE!

In a child with a large left-to-right shunt, oxygen will decrease pulmonary vascular resistance while increasing the systemic vascular resistance, which leads to increased left-to-right shunting. Monitor the child carefully and use oxygen only as prescribed.

Supporting Cardiac Function

Administer digitalis, angiotensin-converting enzyme (ACE) inhibitors, and diuretics as prescribed. Digoxin therapy begins with a digitalizing dose divided into several doses (oral or IV) over a 24-hour period to reach maximum cardiac effect. During digitalization, monitor the electrocardiogram for a prolonged PR interval and decreased ventricular rate. Doses are then administered every 12 hours. Monitor the child for signs of digoxin toxicity. Measure BP before and after administration of ACE inhibitors, holding the dose and notifying the physician if the BP falls greater then 15 mm Hg. Observe for signs of hypotension such as lightheadedness, dizziness, or fainting. Weigh the child daily to determine fluid loss. Maintain accurate records of intake and output, restricting fluid intake if ordered. Carefully monitor potassium levels, administering potassium supplements if prescribed. Sodium intake is not usually restricted in the child with heart failure (Rosenthal et al., 2004).

Providing Adequate Nutrition

Due to the increased metabolic rate associated with heart failure, the infant may require as much as 150 calories/kg/day. Older children will also require higher caloric intake than typical children. Offer small, frequent feedings if the child can tolerate them. During the acute phase of heart failure, many infants in particular will require continuous or intermittent gavage feeding to maintain or gain weight. Concentrate infant formula to 24 to 28 calories/ounce as instructed by the nutritionist.

Promoting Rest

Minimize metabolic needs to decrease cardiac demand. The infant or older child with heart failure will usually limit activities based upon energy level. Ensure adequate time for sleep, and attempt to limit disturbing interventions. Provide age-appropriate activities that can be performed quietly or in bed, such as books, drawing, and video or board games. The older child or adolescent with significant heart failure may require home schooling. As the child improves, a rehabilitation program may be helpful for maximizing activity within the child's cardiovascular status limits.

INFECTIVE ENDOCARDITIS

Infective endocarditis is a microbial infection of the endothelial surfaces of the heart's chambers, septum, or valves (most common). Children with congenital heart defects (septum or valve defects) or prosthetic valves are at increased risk of acquiring bacterial endocarditis, which is potentially fatal in these children. Other risk factors for endocarditis include central venous catheters and intravenous drug use. Infective endocarditis occurs when bacteria or fungi gain access to a damaged epithelium. Turbulence in blood flow associated with narrowed or incompetent valves or with a communication between the systemic and pulmonary circulation leads to damage of the endothelium. Thrombi and platelets then adhere to the endothelium, forming vegetations. When a microbe gains access to the bloodstream, it colonizes the vegetation, using the thrombi as a breeding ground. Clumps may separate from the vegetative patch and travel to other organs of the body, causing significant damage (septic emboli). Fungi or more commonly bacteria (particularly alpha-hemolytic streptococcus or *Staphylococcus aureus*) are frequently implicated in infective endocarditis.

Complete antibiotic or antifungal treatment of the causative organism is necessary, and treatment may last 4 to 7 weeks. Prevention of infective endocarditis in the susceptible child with CHD or a valvular disorder is of utmost importance (Greenberg et al., 2005; Yee, 2005).

Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1285. Assessment findings related to endocarditis are discussed below.

Health History

Obtain the health history, noting intermittent, unexplained low-grade fever. Document history of fatigue, anorexia, weight loss, or flu-like symptoms (arthralgia, myalgia, chills, night sweats). Note history of CHD, valve disorder, or heart failure.

Physical Examination

Measure the child's temperature, noting low-grade fever. Observe for edema if heart failure is also present. Note petechiae on the palpebral conjunctiva, the oral mucosa, or the extremities. Inspect for signs of extracardiac emboli:

- Roth's spots: splinter hemorrhages with pale centers on sclerae, palate, buccal mucosa, chest, fingers, or toes

- Janeway lesions: painless flat red or blue hemorrhagic lesions on the palms or the soles
- Osler's nodes: small, tender nodules on the pads of the toes or fingers
- Black lines (splinter hemorrhages) under the nails

Evaluate the electrocardiogram for a prolonged PR interval or dysrhythmias. Auscultate the heart for a new or changing murmur. Auscultate the lungs for adventitious breath sounds. Palpate the abdomen for splenomegaly (Greenberg et al., 2005; Yee, 2005).

Laboratory and Diagnostic Tests

Diagnosis is usually based on the clinical presentation. Laboratory tests may reveal:

- Blood culture: bacteria or fungus
- CBC: anemia, leukocytosis
- Urinalysis: microscopic hematuria
- Echocardiogram: cardiomegaly, abnormal valve function, area of vegetation

Nursing Management

Nursing management focuses on maintaining IV access for at least 4 weeks to appropriately administer the antibiotic or antifungal course of therapy. Monitor the child's temperature and subsequent blood culture results.

Ideally, infective endocarditis in children should be prevented. Children at increased risk for the development of infective endocarditis include those with:

- Valvular dysfunction or prosthetic valves
- Mitral valve prolapse with regurgitation
- Most congenital heart defects (certain simple septal defects are excluded)
- Surgically constructed systemic-to-pulmonary shunts
- Hypertrophic cardiomyopathy

Children at high risk should practice good oral hygiene, including regular tooth brushing and flossing. Instruct parents or the older child to carry emergency medical identification at all times. A wallet card is available from the American Heart Association at http://www.americanheart.org/presenter.jhtml?identifier=3003000. The card may be presented to any health care provider and includes the recommended antibiotic prophylactic regimen. Instruct the parents to notify the primary care provider or cardiologist if the child develops flu-like symptoms or a fever.

High-risk children (as noted above) who are undergoing procedures that increase the risk for the introduction of the types of bacteria responsible for endocarditis should receive prophylaxis as recommended by the American Heart Association. Usual antibiotics for prophylaxis may include ampicillin, amoxicillin, gentamicin, or vancomycin. Box 40.3 lists procedures for which antibiotic prophylaxis in high-risk children is recommended.

BOX 40.3 Procedures for which Infective Endocarditis Prophylaxis is Recommended

Dental Procedures
- Tooth extractions
- Periodontal procedures
- Dental implant placement
- Replacement of avulsed tooth
- Root canal or surgery
- Intraligamentary local anesthetic injections
- Any prophylactic dental procedure during which bleeding is anticipated

Respiratory Tract Procedures
- Tonsillectomy, adenoidectomy
- Rigid bronchoscopy
- Surgery involving the respiratory mucosa

Gastrointestinal Tract Procedures
- Esophageal varices sclerotherapy
- Dilation of esophageal stricture
- Endoscopic retrograde cholangiography for biliary obstruction
- Other biliary tract surgery
- Surgery involving the gastrointestinal mucosa

Genitourinary Tract Procedures
- Cystoscopy
- Urethral dilation
- Surgery involving the prostate

ACUTE RHEUMATIC FEVER

Acute rheumatic fever (ARF) is a delayed sequela of group A streptococcal pharyngeal infection. In the United States this disease occurs more often in school-age children between 5 and 15 years of age in areas where streptococcal pharyngitis is more prevalent, especially during the colder months. It usually develops 2 to 3 weeks after the initial streptococcal infection. Current understanding of the disease process of ARF is that the child develops an antibody response to surface proteins of the bacteria. The antibodies then cross-react with antigens in cardiac muscle and neuronal and synovial tissues, causing carditis, arthritis, and chorea (involuntary random, jerking movements). ARF affects the joints, central nervous system,

skin, and subcutaneous tissue and causes chronic, progressive damage to the heart and valves. Most attacks of ARF last 6 to 12 weeks and then are resolved, but rheumatic fever may recur with subsequent streptococcal infections.

Diagnosis of ARF is based on the modified Jones' criteria (Box 40.4). Therapeutic management is directed toward managing inflammation and fever, eradicating the bacteria, preventing permanent heart damage, and preventing recurrences. A full 10-day course of penicillin therapy (or equivalent) as well as corticosteroids and nonsteroidal anti-inflammatory drugs are used. Continuous prophylaxis with monthly intramuscular injections of penicillin G benzathine or daily oral doses of penicillin or erythromycin following the initial illness is recommended to prevent a new streptococcal infection and recurrent ARF. Prophylaxis is continued until adulthood (no valvular disease) or age 40 years (with valvular disease) (Martin & Green, 2006).

Nursing Assessment

Elicit a description of the present illness and chief complaint, noting fever and joint pain. Explore the patient's recent medical history for risk factors such as documented streptococcal infection or sore throat within the past 2 to 3 weeks, or for past history of ARF. Observe the child for Sydenham chorea, a movement disorder of the face and upper extremities. Inspect the skin for evidence of the classic rash, erythema marginatum, a maculopapular red rash with central clearing and elevated edges. Auscultate the heart, noting a murmur. Palpate the surfaces of the wrist, elbows, and knees for firm, painless, subcutaneous nodules. Note prolonged PR interval on the electrocardiogram. Throat culture will provide definitive diagnosis of current streptococcal infection, while streptococcal antibody tests may yield evidence of recent infection. Echocardiogram is required to determine if carditis if present.

BOX 40.4 Modified Jones Criteria (American Heart Association)

Diagnosis of acute rheumatic fever requires the presence of either two major criteria or one major plus two minor criteria.

Major Criteria
- Carditis
- Migratory polyarthritis
- Subcutaneous nodules
- Erythema marginatum
- Sydenham chorea

Minor Criteria
- Arthralgia
- Fever
- Elevated erythrocyte sedimentation rate or C-reactive protein
- Prolonged PR interval

Data from Jaggi, P., & Shulman, S. T. (2006). Group A streptococcal infections. *Pediatrics in Review, 27,* 99–105; and Parrillo, S. J., & Parrillo, C. V. (2006). *Rheumatic fever.* Retrieved 11/13/06 from http://www.emedicine.com/emerg/topic509.htm.

Nursing Management

Nursing management of the child with ARF focuses on ensuring compliance with the acute course of antibiotics as well as prophylaxis following initial recovery from ARF. Allow the child to verbalize the frustration he or she may be feeling in relation to chorea symptoms. Offer support for dealing with the abnormal movements. Educate the child and others that the sudden jerky movements of chorea will eventually disappear, though they may last as long as several months. Some children may require a neuroleptic agent such as haloperidol (Haldol) for management of chorea. Administer corticosteroids or nonsteroidal anti-inflammatory agents for control of joint pain and swelling.

CARDIOMYOPATHY

Cardiomyopathy is a condition in which the myocardium cannot contract properly. The incidence of cardiomyopathy among children is increasing; it occurs at a rate of 1.13 per 100,000 (AHA, 2006d). Cardiomyopathy may occur in children with genetic disorders or congenital heart defects, as a result of an inflammatory or infectious process or hypertension, or after cardiac transplantation or surgery, but most commonly it is idiopathic. Cardiomyopathy clusters in infancy and adolescence. Three types of cardiomyopathy exist. Restrictive cardiomyopathy is rare in children and results in atrial relaxation. Dilated cardiomyopathy is the most common type in childhood and may result in heart failure because of ventricular dilatation with decreased contractility. There is some familial tendency toward dilated cardiomyopathy, and it is also associated with Duchenne and Becker muscular dystrophy (Marian et al., 2004). Children with dilated cardiomyopathy may present with heart failure. Hypertrophic cardiomyopathy is more common in adolescence and results in hypertrophy of the heart muscle, particularly the left ventricle, affecting the heart's ability to fill. About two thirds of all cases of hypertrophic cardiomyopathy are familial, with some inherited in an autosomal dominant fashion (Marian et al., 2004; Maron, 2004).

There is no cure for cardiomyopathy, meaning that currently heart muscle function cannot be restored. Therapeutic management is directed toward improving heart function and blood pressure. Mechanical ventilation and

vasoactive medications are needed in many children. ACE inhibitors, beta blockers, or calcium channel blockers may be used. Pacemakers or surgery are helpful in some children. Nearly 40% of children with cardiomyopathy either die or require heart transplantation (Strauss & Lock, 2003).

Nursing Assessment

Explore the health history for risk factors such as:

- Congenital heart defect, cardiac transplantation or surgery
- Duchenne or Becker muscular dystrophy
- History of myocarditis, HIV infection, or Kawasaki disease
- Hypertension
- Drugs, alcohol, or radiation exposure
- Connective tissue, autoimmune, or endocrine disease
- Maternal diabetes
- Familial history of sudden death

Inquire about a history of respiratory distress, fatigue, or poor growth (dilated) or chest pain, dizziness, or syncope (hypertrophic). Observe the child for extremity edema and abdominal distention. Note increased work of breathing. Auscultate the heart, noting tachycardia and irregular rhythm. Evaluate heart rhythm via electrocardiogram, noting dysrhythmias or indications of left ventricular hypertrophy.

Chest x-ray may reveal cardiomegaly or congested lungs. Echocardiogram demonstrates increased heart size, poor contractility, decreased ejection fraction, or asymmetric septal hypertrophy. Cardiac catheterization is usually performed to aid in the diagnosis.

Nursing Management

Many children with cardiomyopathy require intensive care initially. Monitor for complications such as blood clots or arrhythmias, which could lead to cardiac arrest. Refer to the prior section on heart failure for nursing interventions related to heart failure, which may be present with dilated cardiomyopathy. Administer vasoactive and other medications as prescribed, monitoring the child closely for response to these therapies as well as for complications. Support the child in choosing activities that fit within the prescribed restrictions. Provide extensive emotional support to the child and family, who may experience significant stress as they realize the severity of this illness.

HYPERTENSION

Hypertension affects only 1% to 3% of children and adolescents but often leads to long-term health consequences such as cardiovascular disease and left ventricular hypertrophy (Cromwell et al., 2005a). In children, acceptable BP values are based on gender, age, and height. Hypertension is defined as BP persistently greater than the 95th percentile for gender, age, and height. Prehypertension refers to BP that is persistently between the 90th and 95th percentiles. BP is considered normal when the systolic and diastolic values are less than the 90th percentile for gender, age, and height (USDHHS, NHLBI, 2005).

Childhood hypertension may be further defined as primary or secondary. Primary hypertension in children is rare, but its incidence increases with age, so it is more common in adolescence than in early childhood. Hypertension in children most frequently occurs secondary to an underlying medical problem (most often renal disease). Mild to moderate hypertension in childhood is usually asymptomatic and usually is determined only upon BP screening during a well-child visit or during follow-up for known risk factors.

Therapeutic management depends on the extent of the hypertension and the length of time it has existed. Weight reduction, appropriate diet, and increased physical activity are important components of management of prehypertensive and asymptomatic hypertensive children. Some children are candidates for and require antihypertensive medications or diuretics.

Pathophysiology

The balance between cardiac output and vascular resistance determines the BP. An increase in either of these variables, in the absence of a compensatory decrease in the other, increases the mean BP. Factors regulating cardiac output and vascular resistance include changes in electrolyte balance, particularly sodium, calcium, and potassium.

Nursing Assessment

Elicit the health history, determining the presence of risk factors for hypertension such as:

- Family history
- Obesity
- Hyperlipidemia
- Renal disease (including frequent urinary tract infections)
- Systemic lupus erythematosus
- Congenital heart disease
- Neurofibromatosis, Turner syndrome, and other genetic disorders
- Prematurity
- Prolonged neonatal ventilation
- Umbilical artery catheterization
- Diabetes mellitus
- Increased intracranial pressure
- Malignancy
- Solid organ transplant
- Medications known to raise BP

Signs and symptoms reported during the health history might include growth retardation (with certain chronic medical conditions), obesity, and, particularly in older children, headache, subtle behavioral or school performance changes, fatigue, blurred vision, nosebleed, or Bell's palsy.

Determine the child's weight and height/length. Plot these growth parameters on the gender-appropriate chart for the child's age. Note the percentile for height/length, as it will be used to determine the BP percentile (see Appendix F). Measure the BP in all four extremities (to rule out coarctation of the aorta). Ensure that the child is relaxed and sitting or reclined. Refer to Chapter 31 for specific information related to accurate BP measurement in children.

Physical Examination

Inspect the skin for:

- Acne, hirsutism, or striae (associated with anabolic steroid use)
- Café-au-lait spots (associated with neurofibromatosis)
- Malar rash (associated with lupus)
- Pallor, diaphoresis, or flushing (associated with pheochromocytoma)

Observe the extremities for edema (renal disease) or joint swelling (lupus). Inspect the chest for apical heave (ventricular hypertrophy) or wide-spaced nipples (Turner syndrome). Auscultate heart sounds, noting tachycardia (associated with primary hypertension) or murmur (associated with coarctation of the aorta). Palpate the abdomen for a mass or enlarged kidney.

Laboratory and Diagnostic Testing

Though diagnosis of hypertension is based upon BP measurements, additional laboratory or diagnostic tests may be used to evaluate the underlying cause of secondary hypertension, including:

- Urinalysis, blood urea nitrogen, and serum creatinine: may determine presence of renal disease
- Renal ultrasound or angiography: may reveal kidney or genitourinary tract abnormalities
- Echocardiogram: may show left ventricular hypertrophy
- Lipid profile: determines the presence of hyperlipidemia (USDHHS, NHLBI, 2005)

Nursing Management

Salt restriction and potassium or calcium supplements have not been scientifically shown to decrease BP in children (Cook & Daniels, 2005). However, certain children may benefit from salt restriction, as some children seem to be sensitive to salt intake. Assist the child and family to develop a plan for weight reduction if the child is overweight or obese. Encourage the child and family to control portion sizes, decrease the intake of sugary beverages and snacks, eat more fresh fruits and vegetables, and eat a healthy breakfast (USDHHS, NHLBI, 2005). Consult the nutritionist for additional assistance with meal planning. To increase physical activity, the child should find a sport or type of exercise in which he or she is interested. Aerobic activities involving running, walking, or cycling are particularly helpful. When a child requires antihypertensive therapy, teach the child and family how to administer the medication. Caution the parents about side effects related to antihypertensives. Teach the parent to measure the child's BP as determined by the primary care physician or specialist, as well as to keep appointments for BP follow-up. See Healthy People 2010.

KAWASAKI DISEASE

Kawasaki disease is an acute systemic vasculitis occurring mostly in infants and young children. It is the leading cause of acquired heart disease among children and occurs more frequently in the winter and spring (Newburger et al., 2004). Over 4,000 children are hospitalized annually in the United States with Kawasaki disease, and though it affects all ethnic groups, it occurs more frequently in those of Asian or Pacific descent (Newburger et al., 2004). It is a self-limited syndrome but causes serious cardiovascular sequelae in up to 25% of affected children (Newburger et al., 2004). Coronary artery aneurysm results in myocardial infarction and death in some children (Driscoll, 2006a). Therapeutic management of acute Kawasaki disease focuses on reducing inflammation in the walls of the coronary arteries and preventing coronary thrombosis. Chronic management of children developing aneurysms during the initial phase is directed toward preventing myocardial ischemia (Newburger et al., 2004). In the acute phase, high-dose aspirin in four divided doses daily and a single infusion of intravenous immunoglobulin (IVIG) are used. Children whose fever persists longer than 48 hours after initiation of aspirin therapy may receive a second dose of IVIG. Pulsed-dose corticosteroid therapy may also be used to prevent or halt coronary dilatation and inhibit progression to aneurysm (Dummer & Newburger, 2004).

HEALTHY PEOPLE 2010

Objective	Significance
Increase the proportion of persons appropriately counseled about health behaviors	• To prevent development of hypertension, encourage children to maintain a healthy weight and participate in regular exercise.

Pathophysiology

Though the etiology is still unknown, Kawasaki disease may result from an infectious cause. Current thought is that some infectious organism (as yet unidentified) causes disease in genetically susceptible people. Kawasaki disease appears to be an autoimmune response mediated by cytokine-induced endothelial cell surface antigens that leads to vasculitis. Neutrophils, followed by mononuclear cells, T lymphocytes, and immunoglobulin A–producing plasma cells, infiltrate the vessels. Inflammation then occurs in all three layers of the small and medium-sized blood vessels. Edema and smooth muscle necrosis occur in the vessel wall media in severe cases. Generalized systemic vasculitis occurs in the blood vessels throughout the body due to the inflammation and edema. As elastin and collagen fibers fragment, the structural integrity of the vessel wall is impaired. This mechanism leads to coronary dilatation (ectasia) or aneurysm. Some children never develop coronary artery changes, while others develop an aneurysm in either the acute phase or as a long-term sequela. Infants are at the highest risk for coronary aneurysm or ectasia (Newburger et al., 2004).

Nursing Assessment

Nursing assessment consists of determining the health history, physical examination, and laboratory and diagnostic testing.

Health History

Elicit the health history, noting any of the following:

- Fever
- Chills
- Headache
- Malaise
- Extreme irritability
- Vomiting
- Diarrhea
- Abdominal pain
- Joint pain

Of particular note is a history of high fever (39.9°C) of at least 5 days' duration that is unresponsive to antibiotics.

Physical Examination

Observe for significant bilateral conjunctivitis without exudate. Inspect the mouth and throat for dry, fissured lips, strawberry (cracked and reddened) tongue, and pharyngeal and oral mucosa erythema. Note hyperdynamic precordium. Evaluate the skin for:

- Diffuse, erythematous, polymorphous rash
- Edema of the hands and feet
- Erythema and painful induration of the palms and soles
- Desquamation (peeling) of the perineal region, fingers, and toes, extending to the palms and soles
- Possible jaundice

Palpate the neck for cervical lymphadenopathy (usually unilateral) and the joints for tenderness. Palpate the abdomen for liver enlargement. Auscultate the heart, noting tachycardia, gallop, or murmur (Newburger et al., 2004; Rowley, 2004).

Laboratory and Diagnostic Testing

The CBC may reveal mild to moderate anemia, an elevated white blood cell count during the acute phase, and significant thrombocytosis (elevated platelet count [500,000 to 1 million]) in the later phase. The erythrocyte sedimentation rate (ESR) and the C-reactive protein (CRP) level are elevated. Echocardiogram is performed as soon as possible after the diagnosis is confirmed to provide a baseline of a healthy heart or to evaluate for coronary artery involvement. Echocardiograms may be repeated during the illness and as part of long-term follow-up. Occasionally cardiac involvement warrants cardiac catheterization.

Nursing Management

In addition to the administration of aspirin and immunoglobulin, nursing management of the child with Kawasaki disease focuses on monitoring cardiac status, promoting comfort, and providing family education.

Monitoring Cardiac Status

Administer intravenous and oral fluids as ordered, evaluating intake and output carefully. Prepare the child for the echocardiogram. Assess frequently for signs of developing heart failure such as tachycardia, gallop, decreased urine output, or respiratory distress. Evaluate quality and strength of pulses. Provide cardiac monitoring as ordered, reporting arrhythmias.

Promoting Comfort

Provide acetaminophen for fever management and apply cool cloths as tolerated. Keep the environment quiet and cluster nursing care activities to decrease stimulation and hence irritability. Teach parents that irritability is a prominent feature of Kawasaki disease, and support their efforts to console the child. Apply petrolatum jelly or another lubricating ointment to the lips. Encourage the older child to suck on ice chips; the younger child may suck on a cool, moist washcloth. Popsicles are also soothing. Provide comfortable positioning, particularly if the child has joint pain or arthritis.

Providing Patient and Family Education

Teach parents to continue to monitor the child's temperature after discharge until the child has been afebrile for several days. Children with prolonged or recurrent fever may require a second dose of IVIG. Inform parents that irritability may last for up to 2 months after initial diagnosis with Kawasaki disease. Toxic effects of aspirin therapy

such as headache, confusion, dizziness, or tinnitus should be reported to the primary care provider. Nonsteroidal anti-inflammatory agents should be avoided while aspirin therapy is ongoing. For children with continued arthritis (which resolves in several weeks), range-of-motion exercises with a morning bath may help to decrease stiffness. Instruct parents to avoid measles and varicella vaccination for 11 months after high-dose IVIG administration (Newburger et al., 2004). It is critical that the family comply with regularly scheduled cardiology follow-up appointments to determine development or progression of coronary artery ectasia or aneurysm. If the child has severe cardiac involvement, teach the parents about infant and/or child cardiopulmonary resuscitation before discharge from the hospital.

HYPERLIPIDEMIA

Hyperlipidemia refers to high levels of lipids (fats/cholesterol) in the blood. High lipid levels are a risk factor for the development of atherosclerosis, which can result in coronary artery disease, a serious cardiovascular disorder occurring in adults. Children with high lipid levels, though remaining asymptomatic, are likely to have high levels as adults, which increases their risk for coronary artery disease. Therefore, detection, screening, and early intervention are important, especially if there is a family tendency toward heart disease (Armstrong, 2007).

Pathophysiology

Cholesterol is a building block for hormones and cell membranes. It occurs naturally in foods derived from animals such as eggs, dairy products, meat, poultry, and seafood. Cholesterol is also manufactured in the body. Together, cholesterol and triglycerides are known as lipids. Very-low-density lipoprotein (VLDL) is a lipoprotein composed mainly of triglycerides with only small amounts of cholesterol, phospholipid, and protein. VLDLs are easily converted to low-density lipoproteins (LDLs). Cholesterol is expressed in terms of LDL cholesterol or high-density lipoprotein (HDL) cholesterol. LDLs contain relatively more cholesterol and triglycerides than they do protein. HDLs contain about 50% protein, with the rest being cholesterol, triglyceride, and phospholipid. High levels of cholesterol and triglycerides place a person at risk for atherosclerosis. Elevated VLDL and LDL levels and decreased HDL levels produce a particular increase in the risk for atherosclerosis.

Therapeutic Management

Screening children for hyperlipidemia is of prime importance for early detection, intervention, and subsequent prevention of adult atherosclerosis. The National Cholesterol Education Program recommends screening for hyperlipidemia in children over 2 years of age if:

- The parent has a total cholesterol level above 240 mg/dL
- There is a family history of cardiovascular disease in a parent or grandparent before age 55 years
- If the family history is unavailable

All children should eat a diet with the appropriate amount of fats (see the section on nursing management below) and should participate in physical activity. When diet and exercise are not enough to lower cholesterol to appropriate levels, medications such as resins, fibric acid derivatives, statins, or niacin may be used.

Nursing Assessment

Elicit the health history, noting risk factors such as family history of hyperlipidemia, early heart disease, hypertension, diabetes or other endocrine abnormality, cerebral vascular accident, or sudden death. Note prior lipid levels if available. Measure the child's height and weight, plotting them on standardized growth charts. Note overweight or obesity, as these are risk factors associated with hyperlipidemia. Typically, there are no other particular physical findings associated with hyperlipidemia. Table 40.3 gives details about the interpretation of cholesterol levels.

Nursing Management

Instruct families that the child must fast for 12 hours before lipid screening (initially and on follow-up samples). Dietary management is the first step in the prevention and management of hyperlipidemia in children over 2 years of age. The diet should consist primarily of fruits, vegetables, low-fat dairy products, whole grains, beans, lean meat and poultry, and fish. As in adults, fat should account for no more than 30% of daily caloric intake. Fat intake may vary over a period of days, as many young children are picky eaters. Limit saturated fats by choosing lean meats, removing skin from poultry before cooking, and avoiding palm, palm kernel, and coconut oils as well as hydrogenated fats. Teach families to read nutrition labels

TABLE 40.3 INTERPRETATION OF CHOLESTEROL LEVELS FOR CHILDREN AGE 2 TO 19 YEARS

Total Cholesterol (mg/dL)	LDL Cholesterol (mg/dL)	Interpretation
<170	<100	Normal
170–200	100–130	Borderline
>200	>130	High

Gidding, S. S., Dennison, B. A., Birch, L. L., et al. (2006). Dietary recommendations for children and adolescents: A guide for practitioners. *Pediatrics, 117,* 544–559.

to determine the content of the food. Limit intake of processed or refined foods as well as high-sugar drinks; these products provide minimal nutrition and significant calories. Children over 2 years of age should have 60 minutes per day of vigorous play or physical activity. Refer parents to "Healthy Habits for Healthy Kids—A Nutrition and Activity Guide for Parents" published by the American Dietetic Association, available at http://www.wellpoint.com/healthy_parenting/index.html.

If medications are required, teach the child and family about the dose, administration, and possible adverse effects. Assist the family to develop a medication dosing plan that is compatible with school and work schedules to increase compliance.

Heart Transplantation

Heart transplantation is indicated in children with end-stage heart disease related to cardiomyopathy or inoperable CHD. Candidates for heart transplantation are infants and children whose medical and surgical options have been exhausted and who have a 12- to 24-month life expectancy (Gabrys, 2005). Between 350 and 390 children have received a heart transplant each year since 1991 (Boucek et al., 2006). The 5-year survival rate is 75% and the 10-year rate is 65% (Gabrys, 2005).

A comprehensive evaluation is performed to determine whether the child is a candidate for heart transplant. The evaluation includes:

- Chest x-ray, electrocardiogram, echocardiogram, exercise stress test, cardiac catheterization, pulmonary function tests
- CBC with differential, prothrombin and partial thromboplastin time, serum chemistries and electrolytes, blood urea nitrogen, and creatinine
- Urinalysis and urine creatinine clearance
- Blood, throat, urine, stool, and sputum cultures for bacteria, viruses, fungi, and parasites
- Epstein-Barr virus, cytomegalovirus, varicella, herpes, hepatitis, and HIV titers
- HLA typing and panel reactive antibody typing and titer
- Computed tomography or MRI scan, electroencephalogram
- Consults with neurology, psychology, genetics, social work, nutritionist, physical and occupational therapy, and financial coordinator or case manager

Children with irreversible lung, liver, kidney, or central nervous system disease, recent malignancy (past 5 years), or chronic viral infection may be excluded as candidates.

Once candidacy is determined, the transplant center registers the child as a potential recipient with the United Network for Organ Sharing (UNOS). Blood type, body size, length of time on the waiting list, and medical urgency are used to evaluate compatibility. Children awaiting transplantation may need continuous or intermittent hospitalization. Coordination of organ procurement and the transplantation procedure is essential (Canter, 2000; Gabrys, 2005).

Surgical Procedure and Postoperative Therapeutic Management

Most transplantation procedures are **orthotopic**, which means that the recipient's heart is removed and the donor heart is implanted in its place in the normal anatomic position. Cardiopulmonary bypass and hypothermia are used to maintain circulation, protect the brain, and oxygenate the recipient during the procedure. Postoperatively, the child may have near-normal heart function and capacity for exercise and may be able to return to school.

Immunosuppressive therapy is necessary for the rest of the child's life to avoid rejection of the transplanted heart. Usually a three-drug regimen is used that includes calcineurin inhibitors (cyclosporine, tacrolimus), cell toxins (mycophenolate mofetil, azathioprine), and corticosteroids. Ongoing follow-up is provided by the cardiologist and transplant surgeon. Complications of heart transplantation include bacterial, fungal, and viral infection and heart rejection. Neoplasm may occur as a result of chronic immunosuppression.

Nursing Management

Preoperative nursing care for the child undergoing a heart transplant is similar for children undergoing other types of heart surgery. In addition, the nurse should assist with the comprehensive pretransplant evaluation. Care for the child in the post-transplant period is intense and complex. Evaluate the family's ability to perform the tasks that will be necessary. Teach families about the evaluation and transplantation process, as well as the waiting period. In the immediate preoperative period, perform a thorough history and physical examination and obtain last-minute blood work. Provide preoperative teaching similar to other cardiac surgeries. Older children, adolescents, and parents may enjoy the book *Future Conditional* by J. Hatton (1996, Yorkshire Art Circus), which was written by one of the first heart transplant survivors.

Postoperatively, provide frequent assessments and routine care for cardiac surgery patients. In addition, monitor the child closely for infection or signs of rejection. Acute rejection may be indicated by low-grade fever, fatigue, tachycardia, nausea, vomiting, abdominal pain, and decreased activity tolerance, though some children will be asymptomatic. Maintain strict handwashing techniques and isolate the child from other children with infections. Though live vaccines are contraindicated in immunosuppressed children, inactivated vaccines should be given as recommended (Centers for Disease Control and Prevention, 2006). Teach children and families that the child may return to school and usual activities about 3 months after

the transplant. Provide emotional support to the child related to body image changes such as hair growth, gum hyperplasia, weight gain, moon facies, acne, and rashes that occur due to long-term immunosuppressive therapy.

Key Concepts

- At birth, when the umbilical cord is cut and the neonate's first breath occurs, the ductus venosus closes with the foramen ovale and the ductus arteriosus closes shortly thereafter. Pulmonary vascular resistance decreases and systemic vascular resistance increases.
- The infant's heart rate averages 120 to 130 beats per minute and decreases throughout childhood, reaching the adult rate in adolescence. Conversely, the infant and child's blood pressure is significantly lower than the adult's, increasing as the child ages.
- Check the infant's apical pulse prior to digoxin administration and hold the dose if the heart rate is less than 90.
- Poor weight gain, failure to thrive, and increased fatigability commonly occur with congestive heart failure.
- Clubbing of the fingernails occurs as a result of chronic hypoxia in the child with severe congenital heart disease.
- Children with cardiac conditions resulting in cyanosis often have baseline oxygen saturations that are relatively low, because of the mixing of oxygenated with deoxygenated blood.
- Document the presence of a murmur by grading its intensity (I–IV), describing where it occurs within the cardiac cycle, and noting the location where the murmur is best heard.
- Congenital heart disease should be suspected in the cyanotic newborn who does not improve with oxygen administration.
- Cardiac catheterization post-procedure care focuses on evaluation of the child's vital signs and condition of the pressure dressing, as well as assessment of the distal pulses bilaterally for presence and quality.
- Congenital heart disorders resulting in decreased pulmonary blood flow (tetralogy of Fallot, tricuspid atresia) result in cyanosis.
- Disorders with increased pulmonary blood flow (patent ductus arteriosus, atrial septal defect, and ventricular septal defect) may result in pulmonary edema if the defect is severe.
- A decrease in the lower extremity pulses or blood pressure as compared with the upper extremities may be indicative of coarctation of the aorta.
- It is important to remain calm when an infant or child demonstrates a hypercyanotic spell. Place the child in a knee-chest position, administer oxygen and/or morphine or propranolol, and supply intravenous fluids.
- Children with certain congenital heart defects and/or heart failure require additional calories in order to display adequate growth.
- Children with hypertrophic cardiomyopathy, certain congenital heart defects, valve dysfunction, or prosthetic valves require prophylaxis for infective endocarditis when undergoing procedures or invasive dental work.
- Hypertension in the child or adolescent often leads to long-term health consequences such as cardiovascular disease and left ventricular hypertrophy.
- Kawasaki disease may result in severe cardiac sequelae, so these children need ongoing cardiac follow-up to screen for development of problems.
- It is important to screen for hyperlipidemia in high-risk children.
- Abrupt cessation of chest tube output, accompanied by an increase in the heart rate and increased filling pressure, may indicate cardiac tamponade.

Chapter Worksheet

Multiple Choice Questions

1. The nurse is caring for a 5-year-old child with a congenital heart anomaly causing chronic cyanosis. When performing the history and physical examination, what is the nurse least likely to assess?
   a. Obesity from overeating.
   b. Clubbing of the nail beds.
   c. Squatting during play activities.
   d. Exercise intolerance.
2. A 2-day-old infant was just diagnosed with aortic stenosis. What is the most likely nursing assessment finding?
   a. Gallop and rales.
   b. Blood pressure discrepancies in the extremities.
   c. Right ventricular hypertrophy on ECG.
   d. Heart murmur.
3. Sam, age 11, has a diagnosis of rheumatic fever and has missed school for a week. What is the most likely cause of this problem?
   a. Previous streptococcal throat infection.
   b. History of open heart surgery at 5 years of age.
   c. Playing too much soccer and not getting enough rest.
   d. Exposure to a sibling with pneumonia.
4. The nurse is caring for a child after a cardiac catheterization. What is the nursing priority?
   a. Allow early ambulation to encourage activity participation.
   b. Check pulses above the catheter insertion site for strength and quality.
   c. Assess extremity distal to the insertion site for temperature and color.
   d. Change the dressing to evaluate the site for infection.
5. While assessing a 4-month-old infant, the nurse notes that the baby experiences a hypercyanotic spell. What is the priority nursing action?
   a. Provide supplemental oxygen by face mask.
   b. Administer a dose of IV morphine sulfate.
   c. Begin cardiopulmonary resuscitation.
   d. Place the infant in a knee-to-chest position.

Critical Thinking Exercises

1. A baby boy was born at 26 weeks' gestation to 15-year-old unmarried parents who abuse drugs. The infant weighed 1.5 kg at birth and was diagnosed with AV canal defect and Down syndrome. Discuss some of the major issues in planning for care. Include a care plan and a list of teaching needs for the family.
2. A 4-year-old boy has parents with little education, and the child has Medicaid coverage. Another child is 7 years old and has well-educated parents with private insurance coverage. Both of these children need a heart transplant, and a heart is available that is a very good match for both children. Discuss some of the issues involved in deciding which child should receive the heart.
3. A 13-year-old boy was diagnosed with hypertension over 2 years ago. He is noncompliant with his antihypertensive medication regimen. He is 5 feet tall and weighs 170 pounds. His favorite activity is video games. Develop a teaching plan for this teen, providing creative approaches at the appropriate developmental level.

Study Activities

1. Teach a class of sixth graders about healthy activities to prevent high cholesterol levels, hypertension, and heart disease. Use visual materials.
2. Spend the day with a nurse practitioner in the pediatric cardiology clinic. Report to the clinical group your observations about the children's quality of life, growth, and development.
3. Observe in the pediatric cardiothoracic intensive care unit or telemetry unit. Note the different cardiac rhythms displayed by children with a variety of cardiovascular disorders.

CHAPTER 41

Nursing Care of the Child With a Gastrointestinal Disorder

KEY TERMS

ALTE
anal fissure
anastomosis
atresia
cholestasis
cirrhosis
cleft
dysphagia
encopresis
enteral
fecal impaction
fibrosis
guarding
icteric
lethargy
protuberant
pylorus
rebound tenderness
regurgitation
steatorrhea

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Compare the differences in the anatomy and physiology of the gastrointestinal system between children and adults.
2. Discuss common medical treatments for infants and children with gastrointestinal disorders.
3. Discuss common laboratory and diagnostic tests used to identify disorders of the gastrointestinal tract.
4. Discuss medication therapy used in infants and children with gastrointestinal disorders.
5. Recognize risk factors associated with various gastrointestinal illnesses.
6. Differentiate between acute and chronic gastrointestinal disorders.
7. Distinguish common gastrointestinal illnesses of childhood.
8. Discuss nursing interventions commonly used for gastrointestinal illnesses.
9. Devise an individualized nursing care plan for infants/children with a gastrointestinal disorder.
10. Develop teaching plans for family/patient education for children with gastrointestinal illnesses.
11. Describe the psychosocial impact that chronic gastrointestinal illnesses have on children.

Ethan Richardson, 2 months old, is brought to the clinic by his mother. He has been vomiting for the past 3 days. His mother states she switched formula to see if that would help, but the vomiting worsened. Since last night she has attempted to feed him only Pedialyte. Mrs. Roberts says, "He can't keep anything down and he's very irritable." His weight at birth was 8 lbs 9 ounces, length 21 inches, and head circumference 37 cm. At his 2-month check-up last week he weighed 13 lbs.

Wow

Children instinctively eat to live, and the nurse can help them devour the joys that life brings.

Gastrointestinal (GI) disorders affect children of all ages. The most common result of a GI illness is dehydration, requiring fluid therapy at home or, in more extreme cases, in a hospital setting. GI illnesses range from acute to chronic problems. However, even acute, non-life-threatening illnesses (e.g., diarrhea or vomiting) can become life-threatening without proper nursing assessment and interventions. Therefore, all GI disorders should be taken seriously until symptoms are well controlled.

Patient and family education related to the treatment of GI disorders is key to preventing the illness from progressing to an emergency situation. Therefore, the nurse's knowledge of the disorders that affect the GI system is crucial. Most often, the parents or patient will contact the primary care provider in an outpatient setting to seek help. The nurse is usually the person to triage the phone call to determine the next step in the situation, which may be determining whether the patient should be managed at home, brought to the office for assessment, or sent directly to an emergency room for evaluation. The majority of GI disorders can be handled in an outpatient setting to avoid unnecessary hospitalizations, but some life-threatening problems (e.g., bowel obstruction) require emergency care in the hospital. Again, the knowledge base of the nurse is instrumental in obtaining the proper information by taking a thorough and accurate health history from the caregiver or patient.

Variations in Pediatric Anatomy and Physiology

The GI tract includes all of the structures from the mouth to the anus. The primary functions of the GI system are the digestion and absorption of nutrients and water, elimination of waste products, and secretion of various substances required for digestion. Babies are born with GI tracts that are not fully mature until age 2. Due to this immaturity, there are many differences between the digestive tract of the young child and that of the older child or adult.

Mouth

The mouth is highly vascular, making it a common entry point for infectious invaders. In addition, the infant and young child repeatedly bring objects to their mouths and explore them in that fashion. This behavior increases the infant's and young child's risk for contracting infectious agents via the mouth.

Esophagus

The esophagus provides a passageway from the mouth to the stomach for food. The lower esophageal sphincter (LES) prevents **regurgitation** of stomach contents up into the esophagus and/or oral cavity. The muscle tone of the LES is not fully developed until age 1 month, so infants less than 1 month of age frequently regurgitate after feedings. Many children less than 1 year of age continue to regurgitate for several months, but this usually disappears with age. If edema or narrowing of the esophagus occurs in a child with undeveloped esophageal muscle tone, **dysphagia** may occur.

Stomach

Newborns have a stomach capacity of only 10 to 20 mL. At age 2 months an infant has the capacity to hold up to 200 mL, though most young infants cannot tolerate 200-mL feedings. By age 16, the stomach capacity is 1,500 ml; by adulthood it is 2,000 to 3,000 mL. Hydrochloric acid, which is found in gastric contents to aid in digestion, reaches the adult level by age 6 months.

Intestines

A full-term infant has approximately 250 cm of small intestine; an adult has up to 600 cm. The small intestine is not functionally mature at birth. Fat losses may be up to 20% of intake for a newborn, as opposed to 7% for an adult. Intestinal growth occurs in rapid spurts, usually between the age of 1 and 3 years and again at 15 to 16 years. Infants who have small bowel loss during early infancy have more problems with absorption and diarrhea than adults who have the same amount of small bowel loss.

Biliary System

The liver is relatively large at birth, accounting for 5% of the infant's body weight, compared with 2% in an adult. This allows the smooth edge of the liver to be easily palpated in infancy, as much as 2 cm below the costal margin. The pancreatic enzymes all develop at certain postnatal times, not reaching adult levels until 2 years of age.

Fluid Balance and Losses

Children exhibit differences compared with adults that affect the ways that fluid volume is maintained. These differences are evident in body fluid balance and insensible fluid losses.

Body Fluid Balance

Infants and children have a proportionately greater amount of body water than do adults. Infants and young children require a larger relative fluid intake than adults and excrete a relatively greater amount of fluid. This places them at increased risk for fluid loss with illness compared to adults. Until age 2 years, the extracellular fluid makes up about half of the child's total body water. Since extracellular fluid has a larger proportion of sodium and chlo-

ride, when potential fluid-loss states occur, water loss occurs more rapidly and in larger amounts than in adults.

Insensible Fluid Losses

Fever increases fluid loss at a rate of about 7 mL/kg/24-hour period for every sustained 1°C rise in temperature. Since children become febrile with illness more readily and their fevers are higher than those of adults, infants and young children are more apt than adults to experience insensible fluid loss with fever when ill.

Fluid loss via the skin accounts for about two thirds of insensible fluid loss. Infants have a relatively larger body surface area (BSA) than older children and adults. The newborn's BSA is about two or three times greater than the adult's, and the preterm infant's is about five times greater than the adults. This places infants, especially young infants, at increased risk of insensible fluid loss as compared to older children and adults.

The basal metabolic rate in infants and children is higher than that of adults in order to support growth. This higher metabolic rate, even in states of wellness, accounts for increased insensible fluid losses and increased need for water for excretory functions. The young infant's renal immaturity does not allow the kidneys to concentrate urine as well as in older children and adults. This puts infants at particular risk for dehydration or overhydration, depending upon the circumstances.

Common Medical Treatments

There are many different forms of medical treatment for GI disorders. In the hospital setting, most medical treatments will require a physician's order. The most common treatments and medications used for GI disorders are listed in Common Medical Treatments 41.1 and Drug Guide 41.1. Both tables provide essential information about medical treatments and medications used in pediatric GI disorders. These tables should be referred to as needed while completing the remainder of the chapter.

NURSING PROCESS OVERVIEW FOR THE CHILD WITH A GI DISORDER

Nursing care of the child with a GI disorder includes nursing assessment, nursing diagnosis, planning, interventions, and evaluation. Each step of this process must be individualized for each patient. A general understanding of the GI tract and the most common disorders can help the nurse to individualize the nursing care plan.

Remember Ethan, the 2-month-old with vomiting and irritability? What additional health history and physical examination assessment information should you obtain?

Assessment

The assessment of the child with a GI disorder includes a health history, physical examination, and laboratory and diagnostic testing.

Health History

A thorough health history is very important in the assessment of a child with a GI disorder. The health history includes past history (previous illnesses/surgeries), past family history, present illness (when the symptoms began and how this differs from the patient's normal status), and how the patient's symptoms have been managed up to this point (relevant medical records/home treatments). Detailed knowledge of the past medical and surgical history of the patient may reveal bowel resection, previous intestinal infections, and dietary issues and problems. The patient's growth patterns can also be an instrumental part of the health history and may help to generate a timeline for when the current problems appeared. The family history is also extremely important in identifying common genetic/familial GI symptoms or disorders such as irritable bowel syndrome, inflammatory bowel disease, or food allergies. The history of the present illness and symptoms can often distinguish chronic problems from acute disorders. All of these pieces of the health history require descriptive questions and answers from both nurses and patients. The person providing the history must be able to provide accurate details of the health history.

Physical Examination

The physical examination of the child should be done from the least invasive part of the examination to the most invasive. It is important for the child to remain as relaxed as possible during this part of the assessment.

Inspection and Observation

Inspect and observe the child's color, hydration status, abdominal size and shape, and mental status.

Color. First observe the patient's skin, eye, and lip color. Pale skin or lips in a patient with a GI disorder may be a sign of anemia or dehydration. During liver dysfunction, the bilirubin levels can rise, causing the skin to look jaundiced (yellow). The eyes can also become **icteric**, further indicating that the liver is not functioning correctly. Inspect the abdomen for distended veins, which can indicate abdominal or vascular obstruction or distention. As in any part of a physical assessment, watch for areas of ecchymosis, which may be a sign of abuse.

Hydration Status. The child's hydration status often indicates how severe the current GI illness is. Dehydration can occur rapidly in children, especially in infants and young children. The oral mucosa should be pink and moist. Skin turgor should be elastic. Decreased turgor

(text continues on page 1332)

COMMON MEDICAL TREATMENTS 41.1 GASTROINTESTINAL DISORDERS

Treatment	Explanation	Indication	Nursing Implications
Cleansing enema	Insertion of fluid into the rectum to soften the stool and stimulate bowel activity	Fecal impaction, severe constipation	Explain procedure to child prior to enema. With multiple enemas, observe for electrolyte imbalances.
Bowel preparation	Use of highly osmotic fluids to induce severe diarrhea to cleanse the entire bowel	Preparation for colonoscopy or bowel surgery	Some children may need to have a nasogastric tube placed so they can consume the needed amounts of fluids. Observe for signs and symptoms of dehydration/ electrolyte imbalance.
Feeding tubes	Flexible tubes used for enteral feeding when the infant or child is incapable of swallowing safely or for augmenting nutrition. May be orogastric, nasogastric, gastrostomy, or jejunostomy.	Feeding difficulties, failure to thrive, gastro-esophageal reflux disease, chronic illness	Orogastric and nasogastric tubes must be checked for placement prior to each use. If required long term, use a softer, flexible tube intended for long-term use. Stomahesive or Duoderm applied to the cheek may decrease risk of skin breakdown from tape. Gastrostomy tubes vary in type. Keep insertion site clean and dry.
Intravenous therapy	Administration of fluids via a catheter that delivers electrolytes and fluids into the venous system	Dehydration, bowel rest, NPO status	Monitor intravenous site for redness, swelling, and pain. Assess urine output to evaluate hydration status.
Ostomy	A portion of the intestine is brought to the level of the skin to allow passage of stool.	Imperforate anus, gastroschisis, omphalocele, Hirschsprung's disease, necrotizing enterocolitis, Crohn's disease, ulcerative colitis	Ostomy contents may be acidic and irritate the skin. Use Stomahesive or Duoderm under the pouch to avoid tape irritation to the skin. Pouch should fit the stoma correctly. Assess stoma for pinkness and moist appearance.
Oral rehydration therapy	Administration by mouth of fluids that contain certain amounts of electrolytes and glucose to prevent dehydration and/or promote rehydration	Diarrhea, acute gastroenteritis, vomiting	Fluid administration should begin prior to the onset of dehydration. Urine output should be monitored to evaluate hydration status.
Probiotics (lactobacillus, acidophilus)	Food supplement containing dormant bacteria that when activated may alter the intestinal microflora	Treatment/prevention of diarrhea	Particularly helpful in prevention of or decreasing incidence of antibiotic-induced diarrhea.
Total parenteral nutrition (TPN)	Intravenous complete nutrition. Provides glucose, protein, lipids, vitamins, and minerals.	Long-term NPO status, swallowing difficulties, difficulties tolerating enteral feeding (short bowel syndrome, necrotizing enterocolitis)	Higher glucose and protein concentrations and solutions containing calcium require central venous access. Monitor blood glucose levels with initiation, rate changes, and discontinuation. Blood chemistries should be monitored on a regular basis.

DRUG GUIDE 41.1 COMMON DRUGS FOR GI DISORDERS

Classification	Action/Indication	Nursing Implications
Histamine-2 blockers (ranitidine, famotidine, cimetidine, nizatidine)	Decreases histamine production, thereby reducing gastric acid secretion Used for heartburn, esophagitis, GERD, benign duodenal or gastric ulcers.	May cause drowsiness or dizziness
Proton pump inhibitors (omeprazole, lansoprazole, esomeprazole, pantoprazole, rabeprazole)	Blocks the pump that produces gastric acids. Indicated for erosive esophagitis, symptomatic GERD, *H. pylori* eradication.	Adverse effects include headache, nausea, abdominal pain, or diarrhea.
Prokinetics (metoclopramide, cisapride)	Stimulates GI motility to help empty the stomach faster and promote intestinal motility.	Metoclopramide may have central nervous system adverse effects. Cisapride available only in limited-access protocol studies.
Antibacterials/antibiotics (metronidazole, vancomycin)	Treatment of bacterial infections of the GI tract. Used for suspected or proven bacterial infections of the GI tract, such as *C. difficile* or parasitic infections.	May cause GI upset, diarrhea. Very important to finish entire course of treatment.
Immunosuppressants (6-mercaptopurine, azathioprine)	Suppresses the immune system to keep autoimmune disorders in remission such as Crohn's disease, ulcerative colitis, autoimmune hepatitis.	Drug levels should be checked to determine drug metabolite levels and potential for hepatotoxicity or bone marrow suppression.
Stimulants (senna, docusate sodium)	Stimulates peristalsis in the large intestine to produce a bowel movement. Used to relieve constipation.	May cause cramping or diarrhea. Stool patterns should be constantly assessed.
Laxatives (polyethylene glycol, milk of magnesia, lactulose)	Softens the stool to allow for easier passage through the colon. Used to relieve constipation.	Stool patterns should be monitored. Doses may need to be readjusted frequently to find the correct dose for the patient.
Antidiarrheals (loperamide, diphenoxylate/atropine)	Decreases peristalsis, thus prolonging transit time of stool through the intestines. Indicated to treat diarrhea related to short bowel syndrome, chronic nonspecific diarrhea, irritable bowel syndrome.	May cause drowsiness or constipation
Corticosteroids (prednisone)	Acts systemically to reduce inflammation and suppress the normal immune response. Used in inflammatory bowel disease, autoimmune disorders.	Systemic adverse effects include hirsutism, osteoporosis, GI upset, cushingoid appearance, increased intraocular pressure, irritability, and personality changes. Should be taken as directed. Stopping the medication suddenly may cause adrenal insufficiency.
Antiemetics (promethazine, metoclopramide)	Acts on the central nervous system transmitters to prevent nausea and vomiting.	May have central nervous system adverse effects, such as drowsiness or irritability
Anticholinergic/antispasmodics (hyoscyamine, dicyclomine, glycopyrrolate)	Used to control abdominal spasms and cramping associated with irritable bowel syndrome, functional bowel disorders.	May cause excessive thirst or dizziness. Encourage plenty of fluids while taking these medications.
Anti-inflammatory (mesalamine, balsalazide, hydrocortisone enemas/ suppositories, olsalazine, sulfasalazine)	Reduces inflammation in the colon associated with ulcerative colitis, proctitis.	Stool output should be monitored to assess for presence of oral medications (indicating poor absorption).

GERD, gastroesophageal reflux disease.

and tenting indicate dehydration. During crying, especially in infants, the absence of tears may indicate dehydration. Assess the amount of urine output the patient has had in the past 24 hours.

Abdominal Size and Shape. Inspect the size and shape of the abdomen while the child is standing and while lying supine. The abdomen should be flat when the child is supine. An especially **protuberant** abdomen suggests the presence of ascites, fluid retention, gaseous distention, or even a tumor, but many children (toddlers in particular) have a prominent "pot-bellied" abdomen as a normal variation of their anatomy. A depressed or concave abdomen could indicate a high abdominal obstruction or dehydration. Inspect the umbilicus for color, odor, discharge, inflammation, and herniation.

Mental Status. Perform a brief mental status examination of all GI patients. Mental status changes can occur in many instances, such as when ammonia levels are elevated with severe liver disease, severe dehydration, anaphylactic reactions to foods/medicines, tumors, and other metabolic disorders. Irritability and restlessness are usually the early signs of mental status changes. **Lethargy** and listlessness can occur much more rapidly in children than in adults and should be identified promptly and emergently treated.

Auscultation

As with all patients, both pediatric and adult, auscultate bowel sounds in all four quadrants. Hyperactive bowel sounds may be noted in children with diarrhea or gastroenteritis. Hypoactive or absent bowel sounds may signify an obstructive process and should be reported to the physician immediately. Absence of bowel sounds can be determined after a 5-minute period of auscultation. This can be extremely difficult to perform with children and infants, who may be uncooperative during the examination.

Percussion

Dullness or flatness is normally found along the right costal margin and 1 to 3 cm below the costal margin of the liver. The area above the symphysis pubis may be dull in young children with full bladders, which is a normal finding. Percussion of the remainder of the abdomen should reveal tympany. Note abnormal findings.

Palpation

Palpation should be reserved for last in the sequence of abdominal examination. First, lightly palpate the abdomen to assess for areas of tenderness, lesions, muscle tone, turgor, and cutaneous hyperesthesia (a finding in acute peritonitis). Then perform deep palpation from the lower quadrants upward to best feel the liver edge, which should be firm and smooth. In infants and children, palpate the liver during inspiration below the right costal margin. The tip of the spleen may be palpated also during inspiration; it should be 1 to 2 cm below the left costal margin. Palpable kidneys, except in neonates, may indicate tumor or hydronephrosis. The sigmoid colon can be palpated in the left lower quadrant. The cecum may be felt in the right lower quadrant as a soft mass. Areas of firmness or masses may indicate tumor or stool in the abdomen.

Tenderness in the abdomen is not a normal physical finding. Right upper quadrant tenderness could indicate liver enlargement. Right lower quadrant pain, including **rebound tenderness**, can be a warning sign of appendicitis and should be reported to a physician immediately. Palpate the external inguinal canals for presence of inguinal hernias, often elicited by having the child turn the head and cough, or blow up a balloon.

Laboratory and Diagnostic Testing

Common Laboratory and Diagnostic Tests 41.1 gives information about the tests most often ordered by physicians for children with GI illnesses. Some of these tests are ordered in the hospital setting; others are done on an outpatient basis. Typically, the nurse is involved directly in specimen collection while a specifically trained person performs the diagnostic tests. Regardless of who performs the test, nurses must be familiar with preparation guidelines for the patient, how each test is performed, and normal and abnormal findings and their significance so that patient and family education may be provided. Teaching Guidelines 41.1 gives tips on collecting stool specimens.

Nursing Diagnoses, Goals, Interventions, and Evaluation

Upon completion of a thorough assessment, the nurse might identify several nursing diagnoses, including:

- Risk for deficient fluid volume
- Diarrhea
- Constipation
- Risk for impaired skin integrity
- Imbalanced nutrition: less than body requirements
- Pain
- Ineffective breathing pattern
- Risk for caregiver role strain
- Disturbed body image

After completing an assessment on Ethan, you note the following: weight 10 lbs, length 23.5 inches, head circumference 40.75 cm. Head is round with sunken anterior fontanel, eyes appear sunken, mucous membranes are dry, heart rate 158, breath sounds clear with respiratory rate of 42, positive bowel sounds in all four quadrants, difficulty palpating abdomen due to crying. Based on these assessment findings, what would your top three nursing diagnoses be for Ethan?

COMMON LABORATORY AND DIAGNOSTIC TESTS 41.1

Test	Explanation	Indication	Nursing Implications
Abdominal ultrasonography	Visualizes abdominal organs and related vessels	Abdominal pain, vomiting, pregnancy, abnormal liver tests, abdominal mass, enlarged organs on palpation	Barium decreases visualization of organs on ultrasound.
Abdominal x-ray (KUB)	Plain x-ray of the abdomen without contrast media	Constipation, abdominal pain, abdominal distention, ascites, foreign body, palpable mass	Usually ordered as flat and upright to allow for free air and fluid levels in the bowel to be detected.
Amylase (serum)	An enzyme that changes starch to sugar, which enters the blood with inflammation of the pancreas	Acute pancreatitis, pancreatic trauma, acute cholecystitis	Increased levels are seen after 3 to 6 hours of the onset of abdominal pain.
Barium enema	After instillation of barium, fluoroscopically allows visualization of the colon	Constipation, rectal prolapse, bleeding, suspected intussusception	Bowel preparation prior to examination may be ordered. Stool will be light-colored due to barium for a few days.
Electrolytes (serum)	Sodium, potassium, CO_2, chloride, blood urea nitrogen (BUN), creatinine	To determine extent of dehydration	BUN and creatinine may be elevated with dehydration. Sodium, potassium, chloride, and CO_2 levels can be greatly affected with dehydration.
Barium swallow/ upper GI series	Visualizes the form, position, mucosal folds, peristaltic activity, and motility of the esophagus, stomach, and upper GI tract	Foreign body ingestion, abdominal pain, vomiting, dysphagia, malrotation	Females of reproductive age must be screened for pregnancy. Infants may need to be given barium via syringe.
Small bowel series	Done in conjunction with upper GI series to visualize the small intestine contour, position, and motility	Suspected inflammatory bowel disease (bowel wall thickening), intussusception	Very important to encourage large amounts of water/fluids after test to avoid barium-induced constipation.
Endoscopic retrograde cholangio-pancreatography (ERCP)	A fiberoptic endoscope is used to view the hepato-biliary system by instilling contrast to outline the pancreatic and common bile ducts.	Pancreatitis, jaundice, pancreatic tumors, common duct stones, biliary tract disease	Monitor for infection, urinary retention, cholangitis, or pancreatitis after the procedure. Done only occasionally in children.
Esophageal manometry	Tests the esophagus for normal contractile activity and effectiveness of swallowing by measure-ment of intraluminal pres-sures and acid sensors	Abnormal esophageal muscle function, dysphagia, chest pain of unknown cause, esophagitis, vomiting	Often done in conjunction with pH probe. The manometric catheter is placed through the nose into the esophagus. May cause nasal irritation/sore throat.
Esophageal pH probe	A single- or double-channeled probe placed into the esophagus to monitor the pH of the contents that are regurgi-tated into the esophagus from the stomach	Vomiting, gastroesophageal reflux, correlation of symp-toms to gastroesophageal reflux events and high risk for problems, as in asthma, apparent life-threatening event, sinusitis, or choking/ gagging episodes	24-hour study is most accurate. Special diet during study is often used. Accurate diary of symptoms and feedings dur-ing the study is essential. May cause nasal irritation/ sore throat.

(continued)

COMMON LABORATORY AND DIAGNOSTIC TESTS 41.1 (continued)

Test	Explanation	Indication	Nursing Implications
Gastric emptying scan	Assesses the rate at which the stomach empties food into the small intestine by adding isotopes to food and visualizing with scans	Unexplained nausea, vomiting, diarrhea, abdominal cramping	Medications may alter gastric emptying times. Crying or stress during the examination may cause delay in emptying and should be documented.
Hemoccult	Checks for occult blood in the stool	Crohn's disease, ulcerative colitis, malabsorption syndromes, diarrhea, abdominal pain	Indicates bleeding in the GI tract.
Hepatobiliary scan (HIDA scan)	Visualizes the gallbladder and determines patency of the biliary system by use of a radionuclide. The amount of radionuclide ejected from the gallbladder (ejection fraction) is calculated.	Differentiate between biliary atresia and neonatal hepatitis; assess liver trauma, right upper quadrant pain, and congenital malformations	Intravenous line will be established to give radionuclide. Pain during injection should be assessed and documented.
Lactose tolerance test	After ingesting lactose, this tests the hydrogen levels in the breath, which will increase with lactose build-up in the intestines.	Postprandial diarrhea, gassiness, bloating, abdominal pain	May produce similar symptoms during the test itself. A positive test will require diet modification and education regarding lactose intolerance.
Lipase (serum)	An enzyme that changes fat to fatty acids and glycerol appearing in the blood with pancreatic change	Pancreatitis, pancreatic carcinoma, cholecystitis, peritonitis	Lipase levels stay elevated longer with acute pancreatitis.
Liver biopsy	A test done to evaluate the microscopic hepatic structures	Hyperbilirubinemia, jaundice, chronic liver disease, hepatitis	Monitor after procedure for bleeding complications; must maintain strict bed rest for up to 8 hours.
Liver function tests (LFTs) (AST/ ALT/ GGT)	Enzymes that have high concentrations in the liver	Elevations may indicate the severity of liver disease.	May be affected by drugs or viral illnesses
Lower endoscopy (colonoscopy)	Allows visualization and biopsies of the lower GI tract from the anus to the terminal ileum with a fiberoptic instrument	Rectal bleeding, lower abdominal pain, suspected tumors or strictures, foreign body removal	The child must undergo a bowel cleansing prior to the examination. Encourage fluids to prevent dehydration. Conscious sedation or anesthesia care; monitor for possible complications of perforation, bleeding, increased abdominal pain.
Meckel's scan	A gamma camera is used to identify gastric mucosa seen in the distal portion of the ileum after injection of radiopharmaceuticals.	Rectal bleeding, anemia, used only to identify a Meckel's diverticulum	Gloves are worn by nurse during and after scan when radiopharmaceuticals are given.
Oropharyngeal motility study (OPMS)	A study done with different textures to evaluate the dynamics of swallowing and reveal transient abnormalities	Dysphagia, recurrent aspiration	Usually done in combination with therapists and nutritionist.
Rectal suction biopsy	Biopsy is taken of the rectum at different levels to assess for the presence of ganglion cells.	Absence of ganglion cells indicates Hirschsprung's disease.	Infants/children should be assessed for rectal bleeding after examination.

Test	Explanation	Indication	Nursing Implications
Stool culture	Stool is smeared on culture medium and assessed for growth of bacteria over a period of days.	To determine bacterial cause of diarrhea	Requires minimum of 48 hours for growth, several days to weeks in some cases. Can be done with a small amount of stool.
Stool for ova and parasites (O&P)	Checks for the presence of parasites or their eggs in the stool	To determine cause of diarrhea or abdominal pain	Requires about 2 tablespoons of stool.
Upper endoscopy (EGD)	Allows visualization and biopsies of the upper GI tract (mouth to upper jejunum) with a fiberoptic instrument	Dysphagia, foreign body removal, epigastric/abdominal pain, suspected celiac disease	Conscious sedation or anesthesia care; monitor for complications of perforation/bleeding.
Urea breath test	Used to detect the presence of *Helicobacter pylori* in the exhaled breath	*Helicobacter pylori* infection	Patient must not take proton pump inhibitors for 5 days, all antibiotic therapy and Pepto-Bismol for 14 days.

From Pagana & Pagana, 2006.

Nursing goals, interventions, and evaluation for the child with a GI disorder are based on the nursing diagnoses. Nursing Care Plan 41.1 can be used as a guide in planning nursing care for the child with a GI disorder. The nursing care plan should be individualized based on the patient's symptoms and needs. Refer to Chapter 35 for detailed information about pain management. Additional information will be included later in the chapter as it relates to specific disorders.

TEACHING GUIDELINES 41.1

Stool Specimen Collection Variations

- If the child is in diapers, use a tongue blade to scrape a specimen into the collection container.
- If the child has runny stool, a piece of plastic wrap in the diaper may catch the stool specimen. Very liquid stool may require application of a urine bag to the anal area to collect the stool.
- The older ambulatory child may first urinate in the toilet, and then the stool specimen may be retrieved from the new or clean collection container that fits under the seat at the back of the toilet.
- For the bedridden child, collect the stool specimen from a clean bedpan (do not allow urine to contaminate the stool specimen).
- Send the specimen to the laboratory immediately for accuracy of results.

Based on your top three nursing diagnoses for Ethan, describe appropriate nursing interventions.

Stool Diversions

Children may undergo stool diversions for a variety of GI disorders. Surgical procedures involve the creation of an ostomy, primarily an *ileostomy* or *colostomy*, by bringing a portion of the small or large intestine to the surface of the abdomen (Fig. 41.1).

Ostomy pouches are worn over the ostomy site to collect stool. The pouch must be of an appropriate size and it should fit around the stoma properly (Fig. 41.2). The pouch may be tucked inside the diaper or underwear or angled to fit outside of the diaper/underwear. Contemporary pouches cannot be seen under most clothing because they are designed to lie flat against the body. Avoid tight or constricting clothing around the stoma site. Teach families to store ostomy supplies in a cool, dry place. Educate parents to inform school staff that the child should be allowed to use the water fountain and the bathroom without restriction, and the school nurse should have extra ostomy supplies available.

Ostomy care for a child can be challenging due to the child's normal growth and development as well as activity. Empty the ostomy pouch and measure for stool output several times per day. The stool may be semisolid to very liquid in consistency depending on the location of the stoma. Liquid stool output can be acidic, causing irritation

(text continues on page 1338)

Nursing Care Plan 41.1

Overview for the Child with a GI Disorder

NURSING DIAGNOSIS: Fluid volume, risk for deficit: risk factors may include excessive losses through vomiting or diarrhea, inadequate oral intake, possible NPO status (particularly in the surgical client)

Outcome Identification and Evaluation

Child will maintain adequate fluid volume as evidenced by *elastic skin turgor; moist, pink oral mucosa; presence of tears; urine output 1 mL/kg/hr or more.*

Intervention: Maintaining Fluid Balance

- Maintain IV line and administer IV fluid as ordered *to maintain fluid volume.*
- Offer small amounts of oral rehydration solution frequently *to maintain fluid volume. Small amounts are usually well tolerated by children with diarrhea and vomiting.*
- When symptoms have lessened or resolved, reintroduce regular diet *to reduce number of stools, provide adequate nutrition, and shorten duration of effects of illness.*
- Avoid high-carbohydrate fluids such as Kool-aid and fruit juice, *as they are low in electrolytes, and increased simple carbohydrate consumption can decrease stool transit time.*
- Assess hydration status (skin turgor, oral mucosa, presence of tears) every 4 to 8 hours *to evaluate maintenance of adequate fluid volume.*
- Assess adequacy of urine output *to assess end-organ perfusion.*
- Maintain strict intake and output record and weigh child daily *to evaluate effectiveness of rehydration.*
- Weigh child daily: *accurate weight is one of the best indicators of fluid volume status in children.*
- Discourage milk products and fluids that contain high levels of sugar during the acute phase of illness, *as these products may worsen diarrhea.*

NURSING DIAGNOSIS: Diarrhea; may be related to inflammation of small intestines, presence of infectious agents or toxins, possibly evidenced by loose liquid stools, hyperactive bowel sounds, or abdominal cramping

Outcome Identification and Evaluation

Child will experience decrease in diarrhea: *will have bulkier stool as per normal routine.*

Intervention: Relieving Diarrhea

- Maintain clear liquid diet no longer than 24 hours, *as prolonged clear liquids will result in continued liquid ("starvation") stools.*
- Avoid milk products until diarrhea improves: *temporary poor absorption from villus injury follows viral diarrhea.*
- Encourage complex carbohydrate foods *to bulk up the stools.*
- Add fat to carbohydrates *to increase intestinal transit time to encourage water absorption (bulks up stool).*

NURSING DIAGNOSIS: Constipation, related to GI obstructive lesions, pain on defecation, diagnostic procedures, inadequate toileting, or behavioral stool holding, possibly evidenced by change in character or frequency of stools, feeling of abdominal or rectal fullness or pressure, changes in bowel sounds, and abdominal distention

Outcome Identification and Evaluation

Child will experience improvement in constipation *by passing daily soft bowel movement without pain or straining.*

Intervention: Relieving Constipation

- Palpate for abdominal distention, percuss for dullness, and auscultate for bowel sounds *to assess for signs of constipation.*
- Encourage adequate fluid intake *to soften the stool.*
- Administer medications as ordered *to keep stool moving on daily basis.*
- Encourage activity as tolerated: *immobility contributes to constipation.*
- The child with stool withholding should sit on the toilet twice daily, preferably after breakfast and dinner, *to maximize chances for successful stool passage by taking advantage of the gastrocolic reflex.*
- For behavioral stool holding, use rewards or stickers *to encourage appropriate toileting.*

Nursing Care Plan 41.1 (continued)

NURSING DIAGNOSIS: Skin integrity, risk for impaired: risk factors include frequent loose stools, poor nutritional status, presence of stoma, acidic gastric contents contact with skin if gastrostomy present

Outcome Identification and Evaluation

Infant's skin will remain intact: *buttocks skin will be free from rash, excoriation.*
In the child with an ostomy: skin surrounding stoma will remain intact: *free from redness, rash, excoriation.*

Intervention: Maintaining Skin Integrity

- Change diapers frequently *to limit acidic stool content contact with skin.*
- Use barrier diaper cream *to protect skin.*
- Assess skin integrity at every diaper change *to recognize skin changes early so that corrective measures can begin.*
- Leave diaper area open to air several times a day if redness is present *so that air can circulate and skin healing can be facilitated.*
- Use plain water or only mild soap to cleanse the skin with diaper changes *to avoid pH changes that contribute to diaper area skin breakdown.*
- Avoid diaper wipes that contain fragrance or alcohol if the skin is red or has a rash, *as both alcohol and perfume cause stinging if used on non-intact skin and can worsen skin breakdown.*

For the child with an ostomy:

- Ensure proper fit of the ostomy appliance/pouch *to avoid acidic stool contact with skin.*
- Use a barrier wafer (e.g., Stomahesive or Duoderm) to attach appliance: *avoids repeated pulling of adhesive tape from skin.*
- If redness occurs, use barrier/healing cream or paste on skin around stoma *to promote healing and prevent further skin breakdown.*
- Consult enterostomal therapy nurse as needed *to provide additional support.*

NURSING DIAGNOSIS: Nutrition: imbalanced, less than body requirements; may be related to inability to ingest, digest, or absorb nutrients; intestinal pain after eating; decreased transit time through bowel; or psychosocial factors, possibly evidenced by lack of appropriate weight gain or growth, weight loss, aversion to eating, poor muscle tone, or observed lack of intake

Outcome Identification and Evaluation

Nutritional status will be maximized: *child will maintain or gain weight appropriately.*

Intervention: Maintaining Appropriate Nutrition

- Encourage favorite foods (within prescribed diet restrictions if present) *to maximize oral intake.*
- Administer enteral tube feedings as ordered *to maximize caloric intake.*
- Add butter, gravy, cheese as appropriate to foods (if allowed within diet restrictions) *to increase caloric intake.*
- Encourage high-quality, high-calorie snacks between meals, *so as not to interfere with meal intake.*
- Document response to feeding *to determine feeding tolerance.*
- Limit intake of calorie-free beverages: *beverages should contain nutrients and calories.*
- Consult nutritionist *for appropriate diet supplementation recommendations.*

NURSING DIAGNOSIS: Breathing pattern, ineffective, related to postoperative immobility, abdominal pain interfering with breathing, use of narcotic analgesics as evidenced by increased work of or shallow breathing, tachypnea, decrease lung aeration

Outcome Identification and Evaluation

Child will demonstrate effective breathing pattern: *respiratory rate normal for age, absence of accessory muscle use, adequate aeration with clear breath sounds throughout all lung fields.*

Intervention: Promoting Effective Breathing Patterns

- Turn, cough, deep breathe every 2 hours *to encourage adequate aeration and discourage fluid pooling in lungs.* In the infant or toddler, turn every 2 hours and use percusser or chest physiotherapy *to prevent pooling of secretions.*
- Play games to encourage deep breathing (blow out penlight, blow cotton ball across bedside table with straw, etc.): *children are more likely to cooperate with interventions if play is involved.*
- In the developmentally able child, encourage incentive spirometer use every 2 hours *to improve lung aeration.*
- Demonstrate/encourage use of pillow splinting with coughing *to decrease abdominal pain and stress on incision.*

(continued)

Nursing Care Plan 41.1 (continued)

NURSING DIAGNOSIS: Caregiver role strain, risk for: risk factors may include infant with congenital defect, child with chronic illness, marginal caregiver coping patterns, long-term stress, complexity and quantity of care child requires

Outcome Identification and Evaluation

Caregiver will exhibit emotional health: *verbalizes concerns calmly, participates in child's care, and demonstrates knowledge of resources.*

Intervention: Easing Caregiver Role Strain

- Assess parental behavior *to identify role strain.*
- Provide emotional support and encourage talking about feelings, fears, and concerns: *to promote trust in nurse as a source of emotional support.*
- Arrange for and/or encourage respite care for child: *provides parent with time away from continual care.*
- Consult social services *to identify community resources available for caregiver support (home health, support group, etc.).*
- Encourage parent to meet own needs and find personal time *to increase energy level and self-esteem, ultimately enhancing the quality of care given.*

NURSING DIAGNOSIS: Body image disturbance; may be related to presence of stoma, loss of control of bowel elimination, scars from multiple surgical procedures, or effects of treatment regimen, possibly evidenced by verbalization of negative feelings about body, refusal to look at stoma or participate in care

Outcome Identification and Evaluation

Child or teen will demonstrate acceptance of change in body image *by verbalization of adjustment; looking at, touching, caring for body; returning to previous social involvement.*

Intervention: Promoting Proper Body Image

- Observe child's coping mechanisms *to reinforce their use in times of stress.*
- Acknowledge denial, anger, and other feelings as normal *to support child/teen through difficult transition.*
- Allow child gradual introduction to stoma *to ease transition.*
- Encourage child/teen to participate in care, *as this sense of control will contribute to positive self-esteem.*

and severe burn-like areas on the surrounding skin, so special attention to skin care around the ostomy site is essential. Products such as powders and pastes are available to help protect the skin.

The stoma should be moist and pink or red, demonstrating proper circulation to the intestine (Fig. 41.3). Immediately notify the physician if the stoma is not moist and pink or red. Also notify the provider if the volume of stool output is greatly increased, or if the stoma is prolapsed or retracted.

Perform ostomy care as needed; pouches usually need to be changed every 1 to 4 days. The word "stoma"

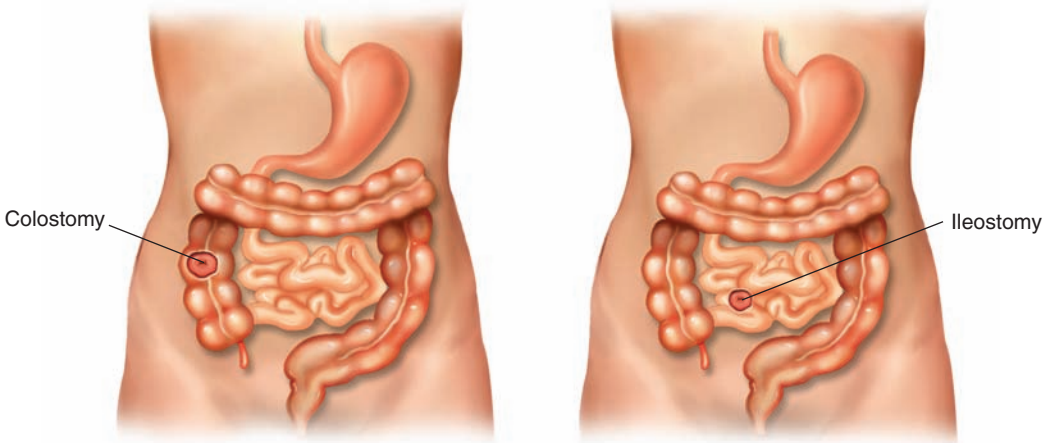

Figure 41.1 A colostomy is a stoma from the colon; an ileostomy is a stoma from the ileum.

FIGURE 41.2 Ensure that the ostomy pouch fits closely around the stoma to prevent irritation of the surrounding skin.

can be used as a mnemonic for the steps for changing an ostomy pouch. See Nursing Procedure 41.1.

Nursing Procedure 41.1

Performing Ostomy Care

1. **S**et up the equipment:
   - Warm, wet washcloths or paper towels
   - Clean pouch and clamp
   - Skin barrier powder, paste, and/or sealant
   - Pencil or pen
   - Scissors
   - Pattern to measure stoma size
2. **T**ake off the pouch (may need to use adhesive remover or wet washcloth to ease pouch removal).
3. **O**bserve the stoma and surrounding skin. Clean the stoma and skin as needed, allowing it to dry thoroughly.
4. **M**easure the stoma, mark the new pouch backing, and cut the new backing to size.
5. **A**pply the new pouch.

Adapted from Children's Healthcare of Atlanta. (2004). *Ostomy care homecare manual.*

Structural Anomalies of the GI Tract

Structural anomalies of the GI tract include cleft lip and palate, omphalocele and gastroschisis, hernias (inguinal and umbilical), and anorectal malformations.

CLEFT LIP AND PALATE

Cleft lip and palate (Fig. 41.4) is the most common congenital craniofacial anomaly, occurring once in every 500–550 births (Tolarova & Oh, 2006). It occurs frequently in association with other anomalies and has been identified in more than 300 syndromes. The most common anomalies associated with cleft lip and palate include heart defects, ear malformations, skeletal deformities, and genitourinary abnormality.

FIGURE 41.3 The healthy stoma is pink and moist.

Complications of cleft lip and palate include feeding difficulties, altered dentition, delayed or altered speech development, and otitis media. The infant with cleft lip may have difficulty forming an adequate seal around a nipple in order to create the necessary suction for feeding and may also experience excessive air intake. Gagging, choking, and nasal regurgitation of milk may occur in babies with cleft palate. Excessive feeding time, inadequate intake, and fatigue contribute to insufficient growth. Primary or permanent teeth may be missing, malformed, or unusually positioned. Children with cleft palate may have slight delays in speech development, a nasal quality to the speech, and difficulty saying certain consonants correctly. The opening in the cleft palate contributes to build-up of fluid in the middle ear (otitis media with effusion), which can lead to an acute infection (acute otitis media). Long-lasting otitis media with effusion leads to temporary and sometimes permanent hearing loss.

Pathophysiology

Development of the **cleft** occurs early in pregnancy. The tissue that forms the lip ordinarily fuses by 5 to 6 weeks of gestation, and the palate closes between 7 and 9 weeks of gestation. Therefore, if either the lip or palate does not fuse, then the infant is born with a cleft. Cleft lip or cleft palate may occur in isolation from one another, but 30% of infants born with cleft lip also have cleft palate (March of Dimes, 2008). The cleft may be unilateral (the left side is affected more often) or bilateral.

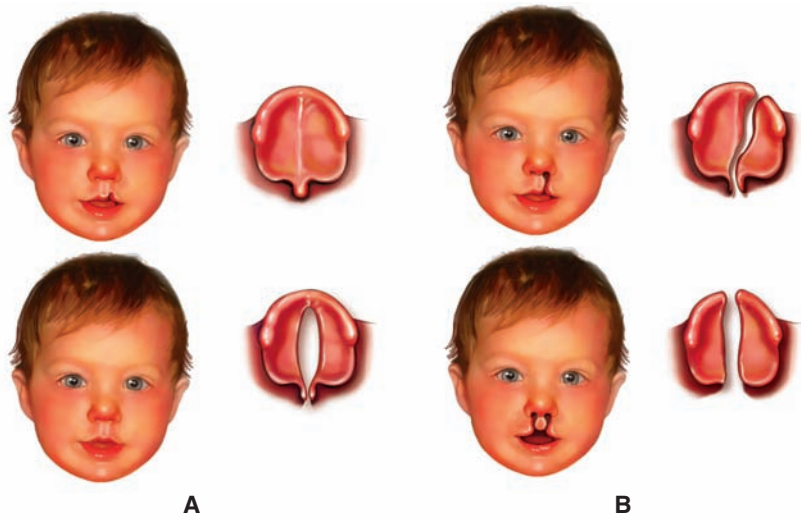

FIGURE 41.4 (**A**) The cleft lip may extend all the way through the vermilion border and up into the nostril, or it may be significantly smaller. (**B**) The cleft palate may be a small opening or may involve the entire palate.

Therapeutic Management

Babies with cleft lip and palate are usually managed by a specialized team that may include a plastic surgeon or craniofacial specialist, oral surgeon, dentist or orthodontist, prosthodontist, psychologist, otolaryngologist, nurse, social worker, audiologist, and speech-language pathologist. Many children's hospitals offer these services in one location, such as a craniofacial specialty center. Historically, cleft lip has been repaired surgically around the age of 2 to 3 months and cleft palate at 9 to 18 months, but in recent years institutions with an experienced craniofacial team have successfully repaired clefts in the neonatal period. Early repair of the cleft lip restores a normal appearance to the child's face and may improve parent–infant bonding. Regardless of the timing of the surgical repair, however, surgical revision of the palate may be required as the child grows.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1329. Assessment findings pertinent to cleft lip and palate are discussed below.

Health History

For the newborn, explore pregnancy history for risk factors for development of cleft lip and palate, which include:

- Maternal smoking
- Prenatal infection
- Advanced maternal age
- Use of anticonvulsants, steroids, and other medications during early pregnancy

When an infant or child with cleft lip or palate returns for a clinic visit or hospitalization, inquire about feeding difficulties, respiratory difficulties, speech development, and otitis media.

Physical Examination

Observe the infant for the presence of the characteristic physical appearance of cleft lip. The cleft may involve the lip only or extend up into the nostril (Fig. 41.5). Cleft palate may be visualized on examination of the mouth. Palpate with a gloved finger to discover mild clefts.

Laboratory and Diagnostic Tests

Cleft lip may be diagnosed by prenatal ultrasound, but it is diagnosed most commonly at birth by the classic physical appearance.

Nursing Management

Refer to the Nursing Care Plan 41.1 for nursing diagnoses and interventions related to airway maintenance, pain alleviation, fluid balance promotion, and restoration of

FIGURE 41.5 Cleft lip.

family processes. These should be individualized for the particular situation. In addition to the nursing diagnoses and related interventions discussed in the Nursing Care Plan, interventions common to cleft lip and palate follow.

Preventing Injury to the Suture Line

It is critical to prevent injury to the facial suture line or to the palatal operative sites. Do not allow the infant to rub the facial suture line. To prevent this, position the infant in a supine or side-lying position. It may be necessary to use arm restraints to stop the hands from touching the face or entering the mouth. Clean the suture line as ordered by the surgeon. Possible care options include using petroleum jelly on the facial suture line or a lip-protective device such as a Logan bow (curved thin metal apparatus) or a butterfly adhesive, both of which protect and maintain the suture line. Protect the palate operative site. Avoid putting items in the mouth that might disrupt the sutures (e.g., suction catheter, spoon, straw, pacifier, or plastic syringe).

Prevent vigorous or sustained crying in the infant, because this may cause tension on either suture line. Ways to prevent crying include administering medications as needed for pain and providing other comfort or distraction measures, such as cuddling, rocking, and anticipation of needs.

Promoting Adequate Nutrition

Preoperatively, the baby with a cleft lip may demonstrate enhanced growth patterns if breastfed. The contour of the breast against the lip may allow for a better seal to be maintained for adequate sucking. Some infants will be fed with a special cleft lip nipple (Fig. 41.6). Parent and surgeon preference will determine the method of feeding. Burp the infant well to expel excess air taken in during difficulty with sucking.

The infant with cleft palate is at risk for aspiration with oral feeding. In some instances a prosthodontic device may be created to form a false palate covering. This device may prevent breast milk or formula from being aspirated. Breastfeeding may be effective in the infant with cleft palate due to the pliability of the breast and the fact that breast tissue may cover the opening in the palate. Postoperatively, some surgeons allow breastfeeding to be resumed almost immediately. In the bottle-fed infant special nipples or feeders may have to be used. When the suture line is healed, ordinary feeding may resume.

Encouraging Infant–Parent Bonding

For some parents, the appearance of a cleft lip is appalling. Encourage parents to hold the medically stable infant immediately after delivery to encourage bonding. Acknowledge normal feelings of guilt, anger, and sadness. Support the parents in providing care for the infant, particularly feeding, which is a viewed as a significant nurturing function. Provide education about the anticipated surgical procedure and eventual normal appearance of the child's lip.

FIGURE 41.6 (**A**) Specialty feeding devices used for infants with cleft lip and cleft palate. (**B**) An infant uses a Haberman Feeder.

Providing Emotional Support

Many families will benefit from support in addition to that received from the craniofacial team. Refer parents to the Cleft Palate Foundation (www.cleftline.org) or a parent-to-parent support network such as www.cleft.org. See Healthy People 2010.

HEALTHY PEOPLE 2010

Objective	Nursing Significance
Increase the number of states and the District of Columbia that have a system for recording and referring infants and children with cleft lips, cleft palates, and other craniofacial anomalies to craniofacial anomaly rehabilitative teams.	• Ensure that your office, clinic, or hospital participates in such a system. • If it does not, advocate for such participation.

MECKEL'S DIVERTICULUM

Meckel's diverticulum is the result of an incomplete fusion of the omphalomesenteric duct during embryonic development. This causes a fibrous band to connect the small intestine to the umbilicus, known as a Meckel's diverticulum (Fig. 41.7). It is the most common congenital anomaly of the GI tract. The risk of complications from Meckel's diverticulum decreases with advancing age, and most affected patients remain asymptomatic. Thus, infants under the age of 1 year are at the greatest risk for complications (21%). The disorder is more common in males than females (Wyllie, 2004d).

The location of a Meckel's diverticulum is on the anterior mesenteric border of the ileum, 40 to 90 cm from the ileocecal valve. The length of the diverticulum can be up to 5 cm and the diameter up to 2 cm (Wyllie, 2004d). The diverticulum contains all of the layers of the intestinal wall, and peptic ulceration of the ileal mucosa adjacent to the ectopic gastric tissue of the diverticulum causes bleeding. Complications associated with Meckel's diverticulum include bleeding, anemia, and intestinal obstruction (most commonly seen as volvulus and intussusception in children).

Surgical correction of the Meckel's diverticulum is necessary in patients who have complications. The surgery is usually done to remove the diverticulum itself. At times, ileal resection is necessary.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1329. Assessment findings pertinent to Meckel's diverticulum are discussed below.

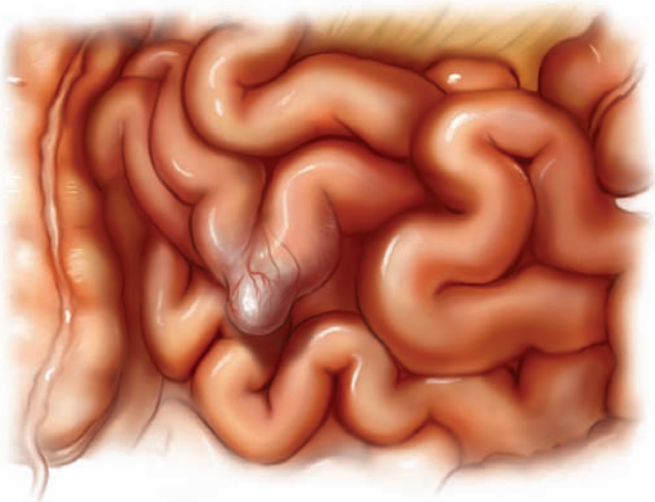

FIGURE 41.7 A Meckel's diverticulum is usually found within 100 cm of the ileocecal valve.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Bleeding
- Anemia
- Severe colicky abdominal pain (in children with associated intestinal obstruction)

Physical Examination

Assess the child for an acute abdomen. Observe for abdominal distention, palpate for an abdominal mass, assess for abdominal **guarding** and rebound tenderness, and auscultate for hypoactive bowel sounds.

Laboratory and Diagnostic Tests

Common laboratory and diagnostic tests ordered for assessment of Meckel's diverticulum include:

- Abdominal x-rays to rule out an acute obstructive process
- Meckel's scan (conclusive)
- Stool tests for color, consistency, and occult blood (usually positive in Meckel's diverticulum)
- Complete blood count (CBC) to assess for anemia

Nursing Management

If anemia is significant, administer ordered blood products (packed red blood cells) to stabilize the patient before surgery. Administer intravenous fluids and maintain NPO status for symptomatic patients while further evaluation is being performed. Immediately report an acute abdomen to a physician. Postoperative care will vary depending on the surgery that was performed. Provide patient and family education as necessary to relieve anxiety related to the diagnosis and surgical intervention. Refer to the Nursing Care Plan 41.1 for additional information.

INGUINAL AND UMBILICAL HERNIAS

Inguinal and umbilical hernias are defects that occur during fetal development. They are one of the most common reasons why infants and children are referred to pediatric surgeons.

Inguinal Hernia

Inguinal hernias occur 9 times more frequently in boys than in girls. Premature infants are particularly susceptible, and 5% have inguinal hernias. Boys are 3 to 10 times more likely to have an inguinal hernia than girls (Sondheimer, 2007). In most cases of inguinal hernia, the processus vaginalis fails to completely close, which then allows the abdominal or pelvic viscera to enter the patent proces-

sus and travel through the internal inguinal ring into the inguinal canal. The hernia sacs that develop most often contain bowel in males and fallopian tubes or ovaries in females. Surgical correction of the inguinal hernia is usually performed when the infant is several weeks old and has been thriving.

Nursing Assessment

Assess infants and children with an inguinal hernia for the presence of a bulging mass in the lower abdomen or groin area (Fig. 41.8). It may be possible to visualize the mass, but often the mass is seen only during crying or straining, making it difficult to actually identify in the clinic setting.

Nursing Management

If a mass is felt upon palpation, the physician may attempt to reduce the hernia by pushing it back through the external inguinal ring. The nurse may be asked to help assist in a reduction, most likely helping to hold the child in a position that will allow the physician to reduce the hernia. If reduction is not possible even with patient sedation, the hernia could be incarcerated. An incarcerated hernia could eventually lead to bowel strangulation.

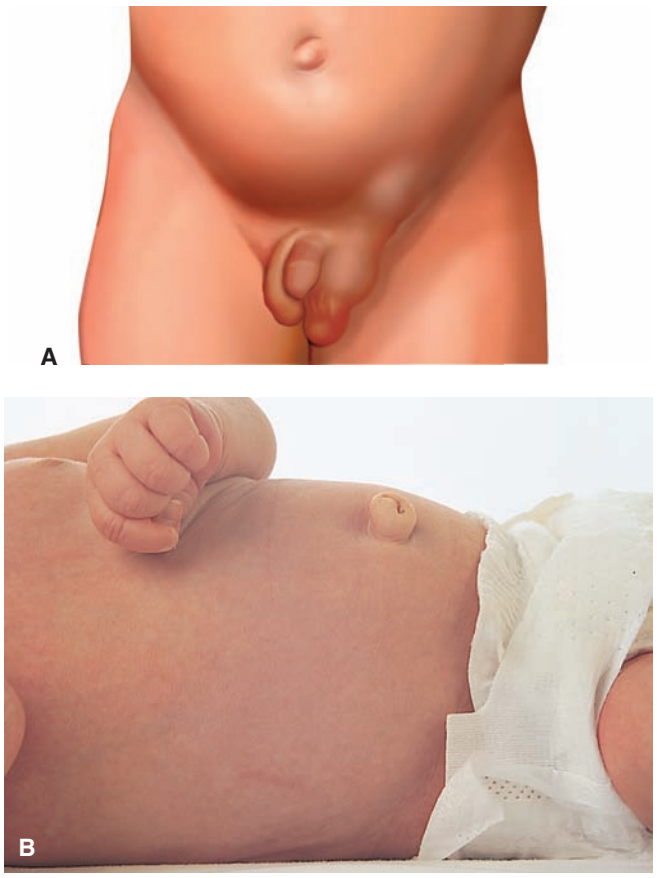

FIGURE 41.8 (**A**) Inguinal hernia: note the bulge in the inguinal (groin) area. (**B**) Umbilical hernia: note the protrusion in the umbilical area.

Reduction is only a temporary method of managing inguinal hernias; they must be corrected surgically. The hernia should be manually reduced as needed until the time of the surgery, so teach the family how to reduce the hernia. Instruct the family to contact the surgeon immediately if the hernia becomes irreducible. Routine pre- and postoperative care is expected during inguinal hernia surgical repair. Provide patient and family education to relieve anxiety.

▶ *Take* NOTE!

Tell the parents that if the child's inguinal hernia becomes hard, discolored, or painful (inconsolable crying), they should immediately call the physician to determine the next course of action (office visit or emergency room visit).

Umbilical Hernia

Umbilical hernia occurs commonly in preterm infants and much more frequently in African-Americans than Caucasians (Sondheimer, 2007). An umbilical hernia is caused by an incomplete closure of the umbilical ring, allowing intestinal contents to herniate through the opening. Unlike inguinal hernias, most umbilical hernias are not corrected surgically. Most children will have spontaneous closure of the umbilical hernia by age 5. Surgical correction is necessary only for the largest umbilical hernias that have failed to close by age 5 years.

Nursing Assessment

Assess whether the hernia can be reduced. Notify the surgeon if the hernia will not reduce. Incarceration is extremely rare, but when it does occur, the child will report abdominal pain, tenderness, or redness at the umbilicus (see Fig. 41.8).

Nursing Management

Since operative repair is not as likely with umbilical hernias as with inguinal hernias, the aim of nursing management is education. Teach the patient and family how to reduce the hernia. The child may have some self-esteem issues related to the large protrusion of the unrepaired umbilical hernia. Teach the child coping skills to help relieve anxiety.

▶ *Take* NOTE!

The use of home remedies to reduce an umbilical hernia should be discouraged because of the risk of bowel strangulation. This includes taping a quarter over a reduced umbilical hernia and the use of "belly bands."

ANORECTAL MALFORMATIONS

Imperforate anus is a congenital malformation of the anorectal opening. The defect is identified in the newborn period. A colostomy must be placed at that time in order to facilitate stool passage (see Chapter 24). Numerous other congenital anomalies may be associated with imperforate anus (Box 41.1). The pediatric nurse may encounter the infant with imperforate anus and an ostomy when the child is admitted to the hospital at several months of age for corrective surgery. Infants often require a staged repair in which the bowel is connected to the anal opening or an anal opening is created (Peña, 2004). When the final repair is achieved, the stoma will be closed and the infant will pass stool through the anal opening.

Nursing Assessment

Perform a thorough physical examination. Note the color, volume, and stool output from the stoma. Ensure that the stoma appears pink and well perfused.

Nursing Management

Preoperatively, provide bowel irrigation as ordered in preparation for the surgery. Maintain NPO status, administer IV fluids as ordered, and monitor fluid volume status.

After the intestinal pull-through procedure is completed, it will be the first time that stool has passed through the anal sphincter. The stool may be quite loose depending on the severity of the imperforate anus. The perianal skin is at significant risk for breakdown, so a barrier cream should be used on that area and it should be cleaned once daily with soap and water. Otherwise, wipe liquid stool off the barrier cream with mineral oil and cotton balls. Most of the barrier cream will remain intact, protecting the infant's perianal area.

BOX 41.1 Anomalies Associated with Anorectal Malformations

- VACTERL syndrome: vertebral, anorectal, cardiovascular, tracheoesophageal, renal, and limb
- Esophageal atresia
- Intestinal atresia
- Malrotation
- Renal agenesis
- Hypospadias
- Vesicoureteral reflux
- Bladder exstrophy
- Cardiac anomalies
- Skeletal anomalies

Take NOTE!

To decrease the drying associated with frequent cleaning, avoid baby wipes and frequent use of soap and water.

Acute GI Disorders

Acute GI disorders include dehydration, vomiting, diarrhea, oral candidiasis, oral lesions, hypertrophic pyloric stenosis, necrotizing enterocolitis, intussusception, malrotation and volvulus, and appendicitis.

DEHYDRATION

Dehydration occurs more readily in infants and young children than it does in adults. The risk is increased in infants and young children because they have an increased extracellular fluid percentage and a relative increase in body water compared to adults. Increased basal metabolic rate, increased body surface area, immature renal function, and increased insensible fluid loss through temperature elevation also contribute to the increased risk for dehydration in infants and young children as compared to adults. Dehydration left unchecked leads to shock, so early recognition and treatment of dehydration is critical to prevent progression to hypovolemic shock. The goals of therapeutic management of dehydration are to restore appropriate fluid balance and to prevent complications.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1329. Assessment findings pertinent to dehydration are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history are included in Comparison Chart 41.1, which compares the clinical manifestations of mild, moderate, and severe dehydration.

Explore the client's current and past medical history for risk factors for dehydration such as:

- Diarrhea
- Vomiting
- Decreased oral intake
- Sustained high fever
- Diabetic ketoacidosis
- Extensive burns

COMPARISON CHART 41.1 **DEHYDRATION**

	Mild	Moderate	Severe
Mental status	Alert	Alert to listless	Alert to comatose
Fontanels	Soft and flat	Sunken	Sunken
Eyes	Normal	Mildly sunken orbits	Deeply sunken orbits
Oral mucosa	Pink and moist	Pale and slightly dry	Dry
Skin turgor	Elastic	Decreased	Tenting
Heart rate	Normal	May be increased	Increased, progressing to bradycardia
Blood pressure	Normal	Normal	Normal, progressing to hypotension
Extremities	Warm, pink, brisk capillary refill	Delayed capillary refill	Cool, mottled or dusky, significantly delayed capillary refill
Urine output	May be slightly decreased	<1 mL/kg/hour	Significantly <1 mL/kg/hour

▶ ***Take*** *NOTE!*

Nurses must be able to assess a child's hydration status accurately and intervene quickly. Children are at higher risk than adults for hypovolemic shock. Dehydrated children may deteriorate very quickly and experience shock.

Physical Examination and Laboratory and Diagnostic Tests

Assess the child's hydration status: heart rate, blood pressure, skin turgor, fontanels, oral mucosa, eyes, temperature and color of extremities, mental status, and urine output. Children usually compensate well initially; their heart rate increases in moderate dehydration, but blood pressure remains normal until it decreases in severe dehydration.

Nursing Management

Nursing goals for the infant or child with dehydration are aimed at restoring fluid volume and preventing progression to hypovolemia. Provide oral rehydration to children for mild to moderate states of dehydration (Dale, 2004) (Teaching Guidelines 41.2). Children with severe dehydration should receive intravenous fluids. Initially, administer 20 mL/kg of normal saline or lactated Ringer's, and then reassess the hydration status (refer to Chapter 52 for further specifics regarding hypovolemic shock).

Once initial fluid balance is restored, the physician may order intravenous fluids at the maintenance rate or as much as 1.5 times maintenance. Maintenance fluid requirements refer to the amount needed under conditions of normal hydration. Maintenance fluid requirements may be determined with the use of the formula found in Box 41.2. In the example provided in Box 41.2, a 23-kg child will need maintenance fluid equivalent to 65 mL/hr.

TEACHING GUIDELINES 41.2

Oral Rehydration Therapy

- Oral rehydration solution (ORS) should contain 75 mmol/L sodium chloride and 13.5 g/L glucose (standard ORS solutions include Pedialyte, Infalyte, and Ricelyte).
- Tap water, milk, undiluted fruit juice, soup, and broth are NOT appropriate for oral rehydration.
- Children with mild to moderate dehydration require 50 to 100 mL/kg of ORS over 4 hours.
- After re-evaluation, oral rehydration may need to be continued if the child is still dehydrated.
- When rehydrated, the child can resume a regular diet.

From Koslap-Petraco, 2006.

BOX 41.2 **Formula for Fluid Maintenance**

- 100 mL/kg for first 10 kg
- 50 mL/kg for next 10 kg
- 20 mL/kg for remaining kg
- Add together for total mL needed per 24-hour period.
- Divide by 24 for mL/hr fluid requirement.

Thus, for a 23-kg child:
- 100 × 10 = 1,000
- 50 × 10 = 500
- 20 × 3 = 60
- 1,000 + 500 + 60 = 1,560

1,560/24 = 65 mL/hr

The same anatomic and physiologic differences that make infants and young children susceptible to dehydration also make them susceptible to overhydration. Thus, continuously evaluate hydration status and be aware of the appropriateness of intravenous fluid orders.

VOMITING

Vomiting is the forceful expulsion of gastric contents through the mouth (Ulshen, 2004c). It occurs as a reflex with three different phases:

- Prodromal period: nausea and signs of autonomic nervous system stimulation
- Retching
- Vomiting

Vomiting in infants and children has many different causes and is considered to be a symptom of some other condition. Table 41.1 lists common causes of vomiting.

Therapeutic management of vomiting most often involves slow oral rehydration and at times may require administration of antiemetics.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1329. Assessment findings pertinent to vomiting are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Note onset and progression of symptoms. The assessment of an infant or child with vomiting should include a history of the vomiting events, including:

- Contents/character of the emesis
- Effort and force of vomiting episodes
- Timing

Contents and character of the vomitus may give clues to the cause of vomiting. Bilious vomiting is never considered normal and suggests an obstruction distal to the ampulla of Vater. Bloody emesis can signify esophageal or GI bleeding. Assess the effort and force of vomiting to identify whether the episodes are effortful and projectile, as with pyloric stenosis, or effortless, as is often seen in gastroesophageal reflux. The timing of the vomiting also is helpful in determining the cause. Vomiting that occurs several hours past meals could signify delayed gastric emptying. When vomiting occurs upon waking or in the middle of the night, particularly if it is associated with headaches, an intracranial lesion or tumor may be suspected. Note any associated events, such as diarrhea or pain.

Diarrhea may occur with viral gastroenteritis or food poisoning. Pain in the epigastric area could signify peptic ulcer disease, pancreatitis, or cholecystitis. Assess the client's past medical history to identify preexisting illnesses, drug abuse, trauma, prescribed medications, and previous abdominal surgery (Ulshen, 2004c). Risk factors for vomiting include exposure to viruses, certain medication use, and overfeeding in an infant.

Physical Examination

Perform a physical examination, noting the child's general appearance. Note hydration status, as well as mental status changes. Note the quality of bowel sounds

TABLE 41.1 CAUSES OF VOMITING BY TEMPORAL PATTERN

Category	Acute	Chronic	Cyclic
Infectious	Gastroenteritis, otitis media, pharyngitis, sinusitis (acute), hepatitis, pyelonephritis, meningitis	*H. pylori, Giardia,* sinusitis (chronic)	Chronic sinusitis
GI	Intussusception, malrotation with volvulus, appendicitis, cholecystitis, pancreatitis	GERD, gastritis, peptic ulcer disease	GERD, malrotation with volvulus
Genitourinary	Ureteropelvic junction obstruction, pyelonephritis	Pregnancy, pyelonephritis	Hydronephrosis
Endocrine/Metabolic	Diabetic ketoacidosis	Adrenal hyperplasia	Diabetic ketoacidosis, Addison's disease, acute intermittent porphyria
Neurologic	Concussion, subdural hematoma, brain tumor	Brain tumor, Arnold-Chiari malformation	Migraines, Arnold-Chiari malformation, brain tumor
Other	Food poisoning, toxic ingestion	Bulimia, rumination	Cyclic vomiting syndrome

GERD, gastroesophageal reflux disease.

upon auscultation. Palpate the abdomen for the presence of abdominal masses, tenderness, or signs of trauma.

Laboratory and Diagnostic Tests

Laboratory studies may be ordered to assess the child's hydration status or to rule out certain causes of vomiting, such as urinary tract infection, pancreatitis, or an acute infectious process. Common laboratory and diagnostic tests ordered for assessment of the cause of vomiting include:

- Abdominal ultrasound
- Upper GI series
- Plain abdominal radiographs

Nursing Management

Nursing management focuses on promoting fluid and electrolyte balance. Oral rehydration is accomplished successfully in most outpatient cases of simple vomiting. Teach the primary caregiver about oral rehydration (refer to Teaching Guidelines 41.2). In the child with mild to moderate dehydration resulting from vomiting, oral feeding should be withheld for 1 to 2 hours after emesis, after which time oral rehydration can begin. Give the infant or child 0.5 to 2 ounces of oral rehydration solution every 15 minutes, depending on the child's age and size. Most infants and children can retain this small amount of fluid if fed the restricted amount every 15 minutes. As the child improves, larger amounts will be tolerated (Dale, 2004).

▶ *Take* NOTE!

Homemade oral rehydration solution can be made by combining 1 quart of water (can be water poured from cooking rice if desired), 8 teaspoons sugar, and 1 teaspoon salt.

If oral rehydration is not possible due to continued nausea and vomiting, intravenous fluids will likely be ordered. In some cases, antiemetics may be used to help control the vomiting. Some antiemetics can cause drowsiness or other side effects and should not be used until a definitive diagnosis is made or severe pathologic processes can be excluded. Educate the family regarding the prevention of vomiting and use of antiemetic therapy.

▶ *Take* NOTE!

Ginger capsules, ginger tea, and candied ginger are generally useful in reducing nausea, are safe for use in children, and usually produce no side effects. Most commercially produced "ginger ale" no longer contains real ginger and so is of limited usefulness (Gardiner & Kemper, 2005).

DIARRHEA

Diarrhea is either an increase in the frequency or a decrease in the consistency of stool (Ulshen, 2004c). Diarrhea in children can either be acute or chronic. Acute infectious diarrhea (gastroenteritis) remains the leading cause of death for children worldwide. In the United States, over 3.5 million infants experience diarrhea yearly, leading to more than 500,000 office visits and 55,000 hospitalizations (Grupka & Wu, 2006).

Pathophysiology

Acute diarrhea in children is most commonly caused by viruses, but it may also be related to bacterial or parasitic enteropathogens. Viruses injure the absorptive surface of mature villous cells, resulting in decreased fluid absorption and disaccharidase deficiency. Bacteria produce intestinal injury by directly invading the mucosa, damaging the villous surface, or releasing toxins. Acute diarrhea may be bloody or nonbloody. The viral, bacterial, and parasitic causes of acute infectious diarrhea are discussed in Box 41.3. Diarrhea may also occur in relation to antibiotic use. Risk factors for acute diarrhea include recent ingestion of undercooked meats, foreign travel, daycare attendance, and well water use.

Though most cases of diarrhea in children are of acute origin, it may also occur chronically. Chronic diarrhea is diarrhea that lasts for more than 2 weeks. This type of diarrhea is not usually caused by serious illnesses. The causes of chronic diarrhea are listed in Box 41.4 according to age groups.

Since most cases of diarrhea are acute and viral in nature, therapeutic management of diarrhea is usually supportive (maintaining fluid balance and nutrition). Probiotic supplementation may decrease the length and extent of diarrhea (Walker & Isolauri, 2007). Bacterial and parasitic causes of diarrhea may be treated with antibiotics or antiparasitic medications, respectively.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1329. Assessment findings pertinent to diarrhea are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Important information related to the course of the diarrhea includes:

- Number and frequency of stools
- Duration of symptoms
- Stool volume
- Associated symptoms (abdominal pain, cramping, nausea, vomiting, fever)
- Presence of blood or mucus in the stool

BOX 41.3 Causes of Acute Infectious Diarrhea

Viral	Bacterial	Parasitic
Rotavirus: characterized by acute onset of fever and vomiting, followed by loose, watery stools; most common cause of viral diarrhea	Salmonella: usually from ingestion of poultry, meats, or dairy products. Infants are at highest risk. Bacteria are excreted for up to 1 year. Severe cases are treated with antibiotics.	*Giardia lamblia:* the most common intestinal parasite in the United States; oral–fecal transmission; sudden onset of watery, foul-smelling stool; often causes gassiness and belching; treated with antiparasitic medications
Adenovirus 40 and 41: second most common cause of viral diarrhea illnesses, similar characteristics to rotavirus	*Escherichia coli* 0157:H7: most often associated with gross bloody stools and abdominal cramping; may lead to hemolytic-uremic syndrome	*Entamoeba histolytica:* oral–fecal transmission; more common outside of United States; colitis symptoms common
Norwalk virus: more common in older children and adults; characterized by vomiting, nausea, and cramping abdominal pain	Campylobacter: symptoms vary from mild diarrhea to dysentery; severe cases may be treated with antibiotics	*Cryptosporidium:* spread via farm animals and people; fecal–oral transmission; watery diarrhea, nausea, vomiting, and flu-like symptoms. No definitive treatment.
Caliciviruses: affected age usually 3 months to 6 years, seen in daycare settings	Shigella: high fevers and bloody stools are common; may cause seizures with fever. Treatment with antibiotics is recommended.	
Astrovirus: affected age usually 1 to 3 years, causing vomiting, diarrhea, fever, and abdominal pain	*Clostridium difficile:* usually related to antibiotic use; may cause pseudomembranous colitis in severe cases. Infants may be carriers of the bacteria and asymptomatic. Treatment with anti-infective medications may be helpful. Probiotic therapy is usually recommended.	
Cytomegalovirus (CMV): causes other medical problems, but may cause diarrhea with colitis	*Yersinia enterocolitica:* usually affects children less than 5 years of age; watery or mucoid diarrhea common, occasionally with gross blood	

BOX 41.4 Causes of Chronic Diarrhea by Age

Infants	Toddlers	School-Age Children
Intractable diarrhea of infancy	Chronic nonspecific diarrhea	Inflammatory bowel disease
Milk and soy protein intolerance	Viral enteritis	Appendiceal abscess
Infectious enteritis	*Giardia*	Lactase deficiency
Hirschsprung's disease	Tumors (secretory diarrhea)	Constipation with encopresis
Nutrient malabsorption	Ulcerative colitis	
	Celiac disease	

Explore the client's current and past medical history for risk factors such as:

- Likelihood of exposure to infectious agents (well water, farm animals, daycare attendance)
- Dietary history
- Family history of similar symptoms
- Recent travel
- Patient age (to identify common etiology for that age group)

Physical Examination

Inspection

Assess the child with diarrhea for dehydration. Observe the child's general appearance and color. In mild dehydration, the child may appear normal. In moderate dehydration, the eyes may have decreased tear production or sunken orbits. Mucous membranes may also be dry. Mental sta-

EVIDENCE-BASED PRACTICE 41.1
Effects of Probiotics Use on the Course of Diarrhea

● Study
Diarrhea (more than three loose, watery stools in a 24-hour period) occurs frequently in children. Most cases of diarrhea are caused by viruses, and symptomatic treatment is the only available therapy. The authors reviewed 23 randomized controlled studies that included a total of over 1,900 participants. The studies evaluated the use of probiotics as compared with placebo or no treatment in relation to the severity and length of diarrhea.

▲ Findings
A variety of probiotics were noted to reduce diarrhea in infants and children as well as adults. Several of the studies demonstrated a shortened course of diarrhea when probiotics were used. The results were statistically significant, leading the authors to determine that probiotic therapy during acute diarrhea may be beneficial.

■ Nursing Implications
Probiotics are available as supplements: capsules or powder that may be sprinkled on food. Additionally, live culture yogurt contains probiotics. Recommend these additions to the diet of older infants or children with acute diarrhea.

Allen, S. J., Okoko, B., Martinez, E., Gregorio, G., & Dans, L. F. (2007). Probiotics for treating infectious diarrhoea. *The Cochrane Library 2007, 4.* Indianapolis: John Wiley & Sons.

tus may be compromised with moderate to severe dehydration, as evidenced by listlessness or lethargy. Skin may be nonelastic or exhibit tenting, signifying lack of proper hydration. Abdominal distention or concavity may be present. Urine output may also be decreased if the child is dehydrated. Stool output may be available to assess for color and consistency. Inspect the anal area for presence of redness or rash related to increased stool volumes and increased frequency.

Auscultation
Auscultate bowel sounds to assess for presence of hypoactive or hyperactive bowel sounds. Hypoactive bowel sounds may indicate obstruction or peritonitis. Hyperactive bowel sounds may indicate diarrhea/gastroenteritis.

Percussion
Percuss the abdomen. Note any abnormalities; the presence of abnormalities on examination for a diagnosis of acute or chronic diarrhea would indicate a pathologic process.

Palpation
Tenderness in the lower quadrants may be related to gastroenteritis. Rebound tenderness or pain should not be found on palpation; if found, it could indicate appendicitis or peritonitis.

Laboratory and Diagnostic Tests
Common laboratory and diagnostic studies ordered for the assessment of diarrhea include:

- Stool culture: may indicate presence of bacteria
- Stool for ova and parasites (O&P): may indicate the presence of parasites
- Stool viral panel or culture: to determine presence of rotavirus or other viruses
- Stool for occult blood: may be positive if inflammation or ulceration is present in the GI tract
- Stool for leukocytes: may be positive in cases of inflammation or infection
- Stool pH/reducing substances: to see if the diarrhea is caused by carbohydrate intolerance
- Electrolyte panel: may indicate dehydration
- Abdominal x-rays (KUB): presence of stool in colon may indicate constipation or **fecal impaction**; air–fluid levels may indicate intestinal obstruction

Nursing Management
Nursing management of the child with diarrhea focuses on restoring fluid and electrolyte balance and providing family education.

Restoring Fluid and Electrolyte Balance
Continue the child's regular diet if the child is not dehydrated. Initial nursing management of the dehydrated child with diarrhea is focused on fluid and electrolyte balance restoration. Refer to the Nursing Care Plan Overview on page 000. Probiotic supplementation while a child is taking antibiotics for other disorders may reduce the incidence of antibiotic-related diarrhea (Walker & Isolauri, 2007). After rehydration is achieved, it is important to encourage the child to consume a regular diet to maintain energy and growth (Brunell, 2006) (see Common Medical Treatments 41.1).

Take NOTE!

Avoid prolonged use of clear liquids in the child with diarrhea because "starvation stools" may result. Also avoid fluids high in glucose, such as fruit juice, gelatin, and soda, which may worsen diarrhea.

Providing Family Education

Teach the parents the importance of oral rehydration therapy (see Teaching Guidelines 41.2). The physician may order medication therapy. In such instances, teach the importance of finishing all prescribed antibiotic therapy. After the cause of the diarrhea is known, teach the child and family how to prevent further occurrences. As most cases of acute diarrhea are infectious, provide education about proper hand washing techniques and transmission route. Chronic diarrhea is often a result of excessive intake of formula, water, or fruit juice, so teach the parents about appropriate fluid intake.

ORAL CANDIDIASIS (THRUSH)

Oral candidiasis (thrush) is a fungal infection of the oral mucosa. It is most common in newborns and infants. Children at risk for thrush include those with immune disorders and those receiving therapy that suppresses the immune system (e.g., chemotherapy for cancer). Children who use corticosteroid inhalers are also at increased risk for the development of thrush. Antibiotic use may also contribute to thrush. Fungal infection may be transmitted between the infant and breastfeeding mother.

Therapeutic management includes treatment with oral antifungal agents such as Mycostatin (nystatin) or fluconazole.

Nursing Assessment

Assess for risk factors for oral candidiasis such as young age, immune suppression, antibiotic use, use of corticosteroid inhalers, or presence of fungal infection in the mother. Inspect the oral mucosa. Thrush appears as thick white patches on the tongue, mucosa, or palate, resembling curdled milk (Fig. 41.9). Unlike milk retained in the mouth, the patches do not easily wipe off with a swab or washcloth. Also assess for presence of candidal diaper rash (beefy-red rash with satellite lesions). Determine the extent to which the presence of the lesions is interfering with the infant's ability to feed. The lesions may cause significant discomfort.

FIGURE 41.9 Thick white patches in the infant with oral candidiasis (thrush).

Diagnosis is usually based on clinical presentation, though a careful scraping of the lesions can be sent out for fungal culture.

Nursing Management

Nursing management of the patient with thrush includes administering medications and providing family education.

Administering Medications

Ensure appropriate administration of oral antifungal agents. Mycostatin suspension should be given four times per day following feeding to allow the medication to remain in contact with the lesions. In the younger infant, Mycostatin can be applied to the lesions with a cotton-tipped applicator. The older infant or child can easily swallow the pleasantly flavored suspension. An advantage of fluconazole is its once-daily dosing, but infants and children receiving it should be monitored for hepatotoxicity. Unlike Mycostatin, fluconazole should be administered with food to decrease the side effects of nausea and vomiting.

Educating the Family

If the mother is also infected, she must receive antifungal treatment as well. Fungal infection of the breast can cause the mother a great deal of pain with nursing, but if appropriately treated breastfeeding can continue without interruption. Appropriate hand washing should be stressed. Bottle nipples and pacifiers need to be kept clean. Infants and young children often mouth their toys, so they should also be cleaned appropriately. Parents of infants with thrush should report diaper rash because fungal infections in the diaper area often occur concomitantly with thrush and also need to be treated.

▶ *Take* NOTE!

Geographic tongue is a benign, noncontagious condition. A reduction in the filiform papillae (bumps on the tongue) occurs in patches that migrate periodically, thus giving a map-like appearance to the tongue, with darker and lighter, higher and lower patches. Do not confuse the lighter patches of geographic tongue with the thick white plaques that form on the tongue with thrush.

ORAL LESIONS

A number of oral lesions may affect infants and children. A few of the most common are aphthous ulcers, gingivostomatitis (from herpes simplex virus), and herpangina. Table 41.2 lists the causes of common oral lesions. Regardless of type, oral lesions are often painful and can interfere with the child's ability to eat. Therapeutic management of oral lesions varies depending on the cause.

Nursing Assessment

Explore the health history for the presence of risk factors such as immune deficiency, cancer chemotherapy treatment, exposure to infectious agents, trauma, stress, or celiac or Crohn's disease. Note the onset of the lesion(s) and progression over time. Question the parent or child about presence of sore throat or dysphagia (occurs with herpangina). Inspect the oral cavity, including the tongue, buccal mucosa, palate, and hypoglossal area. Note presence of lesions and their distribution. Refer to Table 41.2 for descriptions and illustrations of various oral lesions. Inspect the pharynx, which may be red with herpangina. Generally the diagnosis is based on the history and clinical presentation, but occasionally oral lesions are cultured for herpes simplex virus (HSV).

TABLE 41.2 ORAL LESIONS

	Aphthous Ulcers	Gingivostomatitis	Herpangina
Cause	Trauma, vitamin deficiency, celiac disease, Crohn's disease	Herpes simplex virus	Enterovirus (Coxsackie)
Appearance	Erythematous border, often yellow appearance to the ulcer, anywhere on oral mucosa or lips	Vesicular lesions on erythematous base, anywhere in oral cavity, including lips	Bright-red ulcers, generally in posterior oral cavity
Fever	Generally absent	May have high fever with initial outbreak	Abrupt onset of high fever (up to 39.4° to 40.6°C), lasting 1 to 4 days
Length of illness	Generally heal within 7 to 14 days; may recur	10 to 12 days initially; may recur with stress, febrile illness, or intense sunlight exposure (as virus lies dormant in system)	Generally resolves within 5 to 7 days
Therapeutic management	Topical corticosteroid in dental paste may help.	Acyclovir	Supportive treatment only

Nursing Management

The primary concerns with oral lesions are pain management and maintenance of hydration. A corticosteroid-containing dental paste used for aphthous ulcers is formulated to "stick" to mucous membranes, so the lesion area should be as dry as possible prior to application of the paste. Children do not care for having the paste applied and will often resist. Older children with herpangina or stomatitis can "swish and spit" various formulations of "magic mouthwash" (typically a combination of liquid diphenhydramine, liquid acetaminophen, and milk of magnesia); they may offer some pain relief. Common over-the-counter medications such as Ambesol, Oragel, and Kanka may be helpful for topical pain relief, though oral analgesics are often necessary.

The child with herpangina is typically a toddler or preschooler. It may be very difficult to coach a young child to drink fluids when his or her mouth is hurting. Playing games and offering favorite fluids and Popsicles may encourage adequate oral intake. Carbonated beverages and citrus juices should be avoided when oral lesions are present as they can cause further stinging and burning.

▶ *Take NOTE!*

Viscous lidocaine should be used with caution as a topical treatment for numbing the lesions or as a swish-and-spit treatment, as younger children may swallow the lidocaine.

HYPERTROPHIC PYLORIC STENOSIS

Hypertrophic pyloric stenosis is one of the most common conditions requiring surgery in the first 2 months of life. In pyloric stenosis, the circular muscle of the **pylorus** becomes hypertrophied, causing thickness in the luminal side of the pyloric canal (Fig. 41.10). This thickness creates a gastric outlet obstruction, causing nonbilious vomiting. The vomiting becomes more frequent and forceful as time goes on and is often projectile. The incidence is 1 to 8 per 1000 live births and occurs more in males than females (4:1) (Sondheimer, 2007).

The cause of pyloric stenosis is unknown, but a positive family history is present in 13% of patients (Sondheimer, 2007). Infants with pyloric stenosis typically present with symptoms of nonbilious vomiting between weeks 2 and 4 of life.

Pyloric stenosis requires surgical intervention. A pyloromyotomy is performed to cut the muscle of the pylorus and relieve the gastric outlet obstruction (see Fig. 41.10). Postoperative complications are rare.

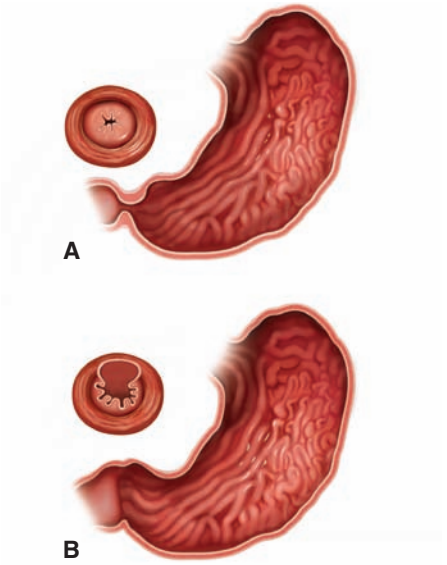

FIGURE 41.10 (**A**) Hypertrophied pylorus muscle and narrowed stomach outlet. (**B**) In pyloromyotomy, the pylorus is incised, thus increasing the diameter of the pyloric outlet.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1329. Assessment findings pertinent to hypertrophic pyloric stenosis are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Forceful, nonbilious vomiting, unrelated to feeding position
- Hunger soon after vomiting episode
- Weight loss due to vomiting
- Progressive dehydration with subsequent lethargy

Risk factors include a positive family history. The disorder occurs most frequently in first-born males.

Physical Examination and Laboratory and Diagnostic Tests

Palpate for a hard, moveable "olive" in the right upper quadrant (hypertrophied pylorus). If an easily palpable mass is felt, no further testing is necessary and a surgical consult is called. If no mass is identified, a pyloric ultrasound may be ordered to identify a thickened hypoechoic ring in the region of the pylorus. An upper GI series may identify pyloric stenosis as well, but an ultrasound is less invasive and is considered more diagnostic of pyloric

stenosis. Assess laboratory values to determine if the infant has metabolic alkalosis resulting from dehydration.

▶ *Take* NOTE!

It may be difficult to examine the infant's abdomen when pyloric stenosis is suspected because of the infant's extreme irritability. A pacifier or nipple dipped in glucose water may soothe the infant long enough to obtain the abdominal examination.

Nursing Management

Preoperative management of infants with pyloric stenosis is aimed at fluid management and correcting abnormal electrolyte values. Family anxiety is high during this time because of the impending surgery for an otherwise healthy infant. Provide emotional support to the family. Teach them about the surgical procedure and what to expect postoperatively. After surgery, infants usually resume oral feedings after 1 to 2 days.

INTUSSUSCEPTION

Intussusception is a process that occurs when a proximal segment of bowel "telescopes" into a more distal segment, causing edema, vascular compromise, and ultimately partial or total bowel obstruction (Fig. 41.11). Intussusception usually occurs in otherwise healthy infants under age 2. It is three times more likely in males than females. Seventy-five percent to 90% of cases of intussusception occur with no specified "lead point" (i.e., pathologic point) that causes the telescoping. When a lead point is identified, it usually occurs in children over age 5. The most common type of lead point is a Meckel's diverticulum, but other lead points may include duplication cysts, polyps, hemangiomas, tumors, the appendix, or even lymphomas (Wyllie, 2004b). Children with cystic fibrosis, celiac disease, and Crohn's disease may be at higher risk for developing intussusception.

A barium enema is successful at reducing a large percentage of intussusception cases; other cases are reduced surgically. If surgical reduction is unsuccessful or bowel necrosis has occurred, a portion of the bowel must be resected.

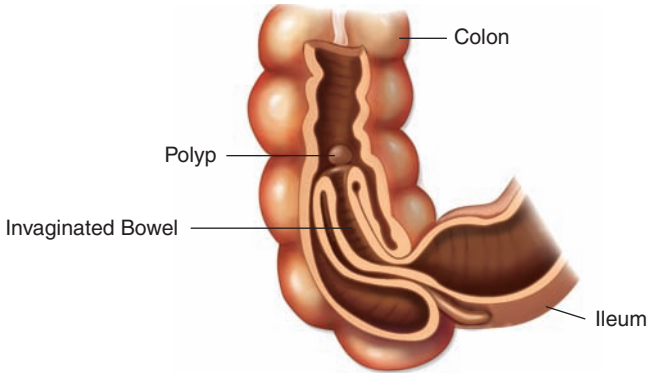

FIGURE 41.11 In intussusception, the intestine telescopes upon itself.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1329. Assessment findings pertinent to intussusception are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Sudden onset of intermittent, crampy abdominal pain
- Severe pain (children usually draw up their knees and scream)
- Vomiting
- Diarrhea
- Currant-jelly stools, gross blood, or Hemoccult-positive stools
- Lethargy

Typically, symptoms flare and then regress. Between episodes, children may have no symptoms of intussusception. This return to a normal state is due to the intussusception reducing on its own. The child may be asymptomatic and may appear well when presenting to the pediatrician or emergency room. Again, this may be a sign that the bowel has reduced spontaneously. Assess the severity of pain, length of time the symptoms have been present, presence of vomiting, and stool patterns and color. Immediately report the presence of bilious vomiting, which occurs only in an obstructive situation. Also assess for signs and symptoms of acute peritonitis. Explore the client's current and past medical history for risk factors, such as cystic fibrosis or celiac disease.

Physical Examination

Palpate the abdomen for the presence of a sausage-shaped mass in the upper mid-abdomen: this is a hallmark sign of intussusception. Note any mental status changes.

Laboratory and Diagnostic Tests

Intussusception is usually diagnosed with an air or barium enema. Use of an enema may show the intussusception and also may reduce it, making the enema therapeutic (Wyllie, 2004b). A pediatric surgeon should be available at the time of the enema in case the enema is unsuccessful or perforation (rare) occurs. White blood cell elevation may occur and electrolytes may show signs of dehydration.

Nursing Management

Administer intravenous fluids and antibiotics before the diagnostic laboratory and radiograph studies are performed. Refer to the Nursing Care Plan 41.1 for nursing management of the postoperative child.

The parents may be very fatigued after dealing with a crying infant. They are often quite anxious about surgery in an otherwise healthy child. Offer emotional support and provide appropriate preoperative and postoperative education to the family.

MALROTATION AND VOLVULUS

Intestinal malrotation occurs during the 10th week of embryonic development. At week 10, the intestine is anchored to the abdominal wall by the base of the mesentery in a specific pattern to avoid kinking or twisting (Wyllie, 2004c). When malrotation occurs, the intestine is abnormally attached and the mesentery narrows, twisting on itself (volvulus). If the volvulus involves the entire small bowel, it is termed a mid-gut volvulus.

The main symptom of malrotation is bilious vomiting. Many children also have abdominal pain, shock symptoms, abdominal distention, tachycardia, and bloody stools. Most cases of malrotation will present in the first few weeks of life, but symptoms may not occur until the patient is well into adulthood.

Therapeutic management of malrotation and volvulus is accomplished surgically. A Ladd procedure is performed, during which the intestine is straightened out and bands contributing to the misalignment are divided. If bowel necrosis has occurred (rare), then an ostomy may be necessary.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1329. Assessment findings pertinent to malrotation and volvulus are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include vomiting and abdominal pain. Since obstruction can occur with resulting necrosis of the bowel, immediately inform the physician if obstruction is suspected.

Physical Examination and Diagnostic and Laboratory Tests

Observe for severity of pain, palpate for abdominal guarding and rebound tenderness, and auscultate for hypoactive bowel sounds. Common laboratory and diagnostic studies ordered for the assessment of malrotation and volvulus include:

- KUB to reveal obstruction
- Upper GI series to identify the location of the duodenojejunal junction and corkscrew appearance of the twisted bowel

Nursing Management

When diagnostic testing reveals malrotation/volvulus, administer ordered intravenous fluids and intravenous antibiotics. Often a nasogastric tube is placed to decompress the stomach. Surgery is performed as soon as possible. After surgery, provide postoperative care of the child (see Nursing Care Plan 41.1). Provide continuous emotional support and family education.

APPENDICITIS

Appendicitis, an acute inflammation of the appendix, is the most common cause of emergent abdominal surgery in children. It occurs in all age groups; the median age in the pediatric population is 4 to 15 years (Albanese & Sylvester, 2006).

Pathophysiology

Appendicitis is due to a closed-loop obstruction of the appendix (Fig. 41.12). It is thought that the obstruction is due to fecal material impacted into the relatively narrow appendix, though other causes such as ingested foreign bodies may exist. This causes a subsequent increase in the intraluminal pressure of the appendix, resulting in mucosal edema, bacterial overgrowth, and eventual perforation. Due to the fecal material in the appendix, perforation causes inflammatory fluid and bacterial contents to leak into the abdominal cavity, resulting in peritonitis. Diffuse peritonitis is more likely in younger children. Older children and adolescents have a more developed omentum, which walls off the inflamed or perforated appendix, often causing a focal abscess.

Therapeutic Management

Appendicitis is considered a surgical emergency because if left uncorrected, the appendix may perforate. Surgical removal of the appendix is necessary and is often accomplished via minimally invasive laparoscopic technique. In the case of perforation, an open surgical procedure is usually required, and lavage of the abdominal cavity may be performed to cleanse it of the infected fluid released from the appendix.

Nursing Assessment

Early diagnosis and intervention are the key elements to avoid perforation. For a full description of the assessment phase of the nursing process refer to page 1329. Assessment findings pertinent to appendicitis are discussed below.

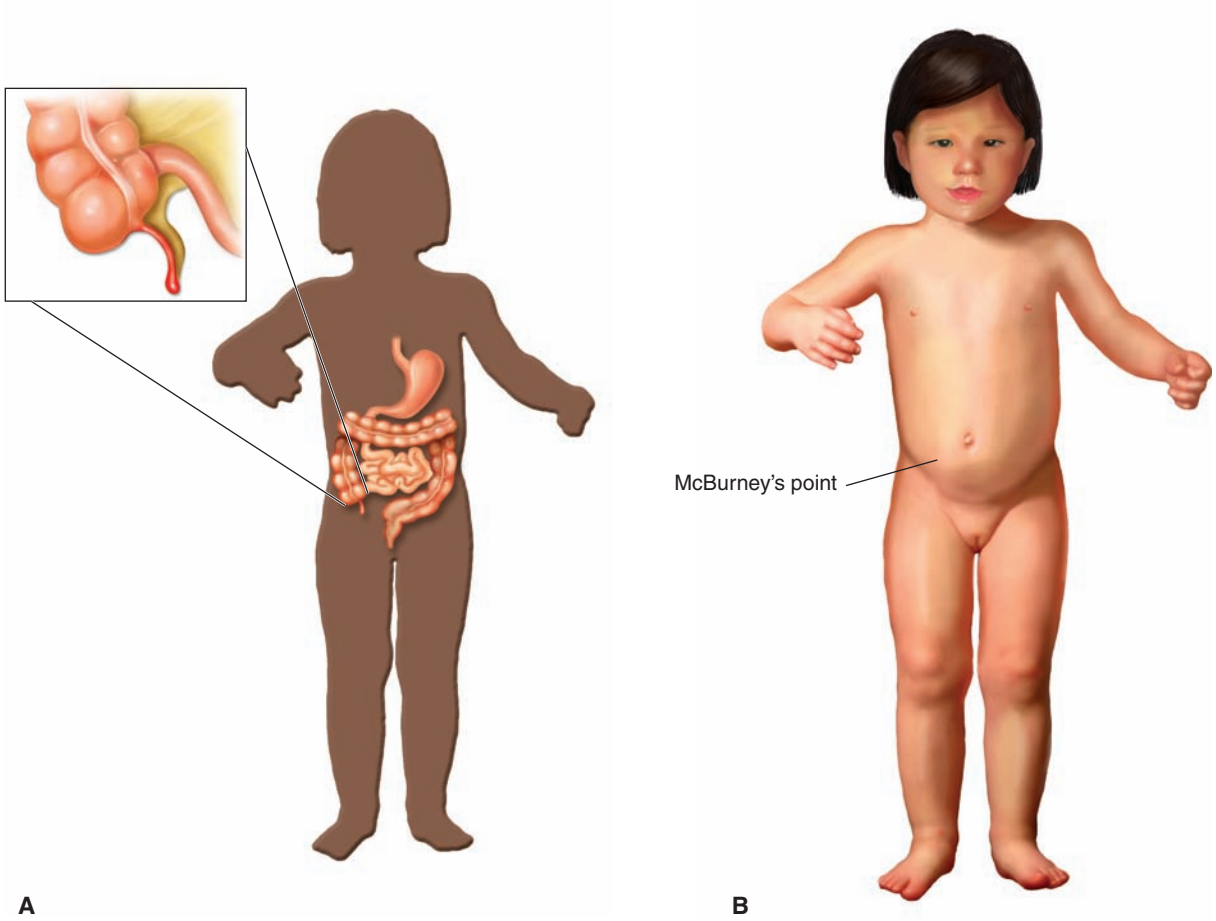

FIGURE 41.12 (**A**) In appendicitis, the lumen of the appendix is obstructed, resulting in edema and compressed blood vessels. (**B**) As appendicitis progresses, pain may become localized at McBurney's point (a point midway between the anterior superior iliac crest and the umbilicus).

Health History

Elicit a description of the present illness and chief complaint. Appendicitis may be gradual, and symptoms usually do not come and go; they remain persistent and intensify. Common signs and symptoms reported during the health history might include:

- Vague abdominal pain in the initial stages, localizing to the right lower quadrant over a few hours
- Nausea and vomiting (which usually develop after the onset of pain)
- Small-volume, frequent, soft stools, often confused with diarrhea
- Fever (usually low grade unless perforation occurs, which results in high fever)

Physical Examination

Children with appendicitis often appear anorexic and ill. They often cannot walk or climb up onto the examination table without assistance. Upon palpation, maximal tenderness occurs over McBurney's point in the right lower quadrant (see Fig. 41.12). Assess the abdomen for acute peritonitis, as indicated by diffuse abdominal tenderness or distention. Immediately report positive findings to a physician.

▶ ***Take*** NOTE!

If the child's abdominal pain is suddenly relieved without intervention, suspect perforation and notify the physician immediately.

Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of appendicitis include:

- Abdominal computed tomography (CT) scan: performed to visualize the appendix for further evaluation
- Laboratory testing: may reveal an elevated white blood cell count
- C-reactive protein: may be elevated

Nursing Management

Provide pre- and postoperative care and patient and family education (see Nursing Care Plan 41.1). Care depends on what was found during surgical exploration. A nonruptured, nongangrenous appendix usually requires no antibiotic therapy, so provide routine surgical care. In addition to routine surgical care, administer 48 to 72 hours of ordered antibiotics to the child with a suppurative or gangrenous (nonperforated) appendix to decrease the risk of postoperative infection. The child with a perforated appendix will require 7 to 14 days of intravenous antibiotic therapy in addition to normal postoperative care. Provide family teaching, because the child is often discharged home while still receiving intravenous antibiotic therapy.

Chronic GI Disorders

Chronic GI disorders include gastroesophageal reflux, peptic ulcer disease, constipation/encopresis, Hirschsprung's disease, short bowel syndrome, inflammatory bowel disease, celiac disease, recurrent abdominal pain, failure to thrive, and chronic feeding problems.

GASTROESOPHAGEAL REFLUX

Gastroesophageal reflux (GER) is passage of gastric contents into the esophagus. It is considered a normal physiologic process that occurs in healthy infants and children. However, when complications develop from the reflux of gastric contents back into the esophagus or oropharynx, it becomes more of a pathologic process known as gastroesophageal reflux disease (GERD). GER occurs frequently during the first year of life; most infants outgrow the reflux by age 6 months. GER is particularly common in premature infants. Other possible diagnoses that can be mistaken for GER include food allergies, formula enteropathies, gastric outlet obstruction, malrotation, cyclic vomiting, or central nervous system lesions.

Pathophysiology

The process of GER occurs during episodes of transient relaxation of the LES, which can occur during swallowing, crying, or other Valsalva maneuvers that increase intraabdominal pressure. Delayed esophageal clearance and gastric emptying, highly acidic gastric contents, hiatal hernia (protrusion of the stomach upward into the mediastinal cavity through the esophageal hiatus of the diaphragm), or neurologic disease may also be contributing factors associated with reflux.

Symptoms of GERD in infants and children are listed below in the health history section. The signs and symptoms of GERD are often seen as a result of the damaging components of the refluxate (the pH of the gastric contents, bile acids, and pepsin). The longer the pH of the refluxate is below 4, the higher the risk for development of severe GERD.

As a result of GERD, other systems may be at risk for damage. These complications include esophagitis, esophageal stricture, Barrett's esophagus (a precancerous condition), laryngitis, recurrent pneumonia, asthma, or anemia from chronic esophageal erosion.

Therapeutic Management

Conservative medical management begins with appropriate positioning, such as elevating the head of the bed and keeping the infant or child upright for 30 minutes after feeding. Smaller, more frequent feedings may be helpful. If reflux does not improve with these measures, medications are prescribed to decrease acid production and stabilize the pH of the gastric contents. Also, prokinetic agents may be used to help empty the stomach more quickly, minimizing the amount of gastric contents in the stomach that the child can reflux.

If the GERD cannot be medically managed effectively or requires long-term medication therapy, surgical intervention may be necessary. A Nissen fundoplication is the most common surgical procedure performed for antireflux therapy. The gastric fundus is wrapped around the lower 2 to 3 cm of the esophagus (Fig. 41.13). Laparoscopic fundoplications are being performed as a way to minimize the recovery period and reduce potential complications.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1329. Assessment findings pertinent to gastroesophageal reflux are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Note onset and progression of symptoms. Com-

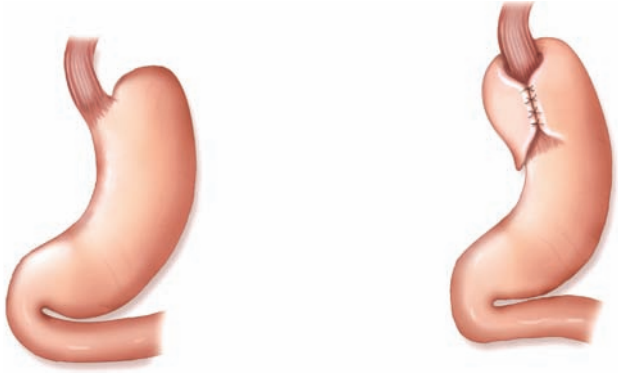

FIGURE 41.13 In the Nissen fundoplication, the fundus (upper portion of the stomach) is wrapped around the lower segment of the esophagus.

mon signs and symptoms reported during the health history include:

- Recurrent vomiting or regurgitation
- Weight loss or poor weight gain
- Irritability in infants
- Respiratory symptoms (chronic cough, wheezing, stridor, asthma, apnea)
- Hoarseness/sore throat
- Halitosis (mostly in older children)
- Heartburn or chest pains
- Abdominal pain
- Abnormal neck posturing (Sandifer syndrome)
- Hematemesis
- Dysphagia or feeding refusal
- Chronic sinusitis, otitis media
- Poor dentition (caused by acid erosion)

Explore the patient's current and past medical history for risk factors such as:

- Prematurity, noting prolonged ventilator use or chronic lung disease
- Dietary habits (e.g., chocolate, coffee, spicy or fatty foods, caffeine, formula-fed or breastfed, overeating or overfeeding)
- Current medications
- Smoking/alcohol use (older children)
- Food allergies
- Other GI disorders (gastric outlet dysfunction/hiatal hernia) or congenital abnormalities
- Feeding positions and patterns (especially important in infants)
- Sleeping positions/patterns
- Other medical history, such as asthma, recurrent infections/pneumonia

Physical Examination

The physical examination consists of inspection, auscultation, percussion, and palpation.

Inspection

Observe the child's general appearance and color. Infants and children with uncontrolled GER for a period of time may appear underweight or malnourished. Infants may be irritable due to painful regurgitation/reflux events. Note breathing patterns, because reflux-induced asthma may have developed. **Acute life-threatening events** (ALTE) and apnea have been associated with severe GERD. Observe the child for cyanosis, altered mental status, and alterations in tone. Inspect emesis for blood or bile.

Auscultation

Evaluate the lung fields for the presence of complications related to GERD, such as wheezing or pneumonia. No further pathologic findings related to GERD should be auscultated on examination.

Percussion

Perform routine abdominal percussion, noting any abnormalities. No specific findings should be noted.

Palpation

Use caution when palpating the abdomen, especially with infants with GER, because it may induce vomiting. No abnormalities should be palpated.

▶ *Take NOTE!*

Not all infants with GERD actually vomit. Those with "silent" GERD may only demonstrate irritability associated with feeding or posturing (arching back during or after feeding) and grimacing. Episodes of GERD often cause bradycardia, so if the above signs occur, they should be reported to the physician, even if the baby is not vomiting.

Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of gastroesophageal reflux include:

- Upper GI series: though not sensitive or specific to GER, may show some reflux; used to narrow down the differential diagnosis
- Esophageal pH probe study: quantifies GER episodes as they correlate to symptoms
- Esophagogastroduodenoscopy (EGD): shows esophageal and gastric tissue damage from GERD
- Complete blood count: may demonstrate anemia if chronic esophagitis or hematemesis is present
- Hemoccult: may be positive if chronic esophagitis is present

Nursing Management

As with most GI disorders, initial nursing management is aimed at restoring proper fluid balance and nutrition. Refer to the Nursing Care Plan on page 1336. Additional considerations are reviewed below.

Promoting Safe Feeding Techniques and Positioning

Feeding adjustments are an essential part of reflux management. Give infants smaller, more frequent feedings using a nipple that controls flow well. Frequently burp the infant during feeds to control reflux. Thickening of the formula with products such as rice or oatmeal cereal can significantly help keep the formula and gastric contents down. Positioning after feedings is important. Keep infants upright for 30 to 45 minutes after feeding. For infants, elevate the head of the crib 30 degrees. For older children, elevate the head of the bed as much as possible and restrict meals for several hours before bedtime. While the proper

positioning of an infant with GERD for sleep is controversial, infants can be positioned safely on their sides or upright in a car seat to minimize the risk of aspiration while on their backs. However, individual physicians may have specific preferences about sleeping positions for infants with GERD.

Maintaining a Patent Airway

GERD symptoms often involve the airway. Maximize reflux precautions to keep the risk of airway involvement to a minimum. In rare instances, GERD causes apnea or an ALTE. In these cases, use an apnea or bradycardia monitor to monitor for such episodes. The monitor requires a physician's order and can be ordered through a home health company. Teach parents how to deal with these episodes, as their anxiety is very high. Provide CPR instruction to all parents whose children have had an ALTE previously.

Educating the Family and Child

The goals for the infant and child with gastroesophageal reflux are a decrease in symptoms, a decrease in the frequency and duration of reflux episodes, healing of the injured mucosa, and prevention of further complications of GERD. Teach the parents the signs and symptoms of complications. Explain that reflux is usually limited to the first year of life, though in some cases it persists. If medications are prescribed, thoroughly explain their use and their side effects (see Drug Guide 41.1).

Providing Postoperative Care

If the child requires fundoplication, a gastrostomy tube is often placed for use in the immediate postoperative period or for long-term feeding. In the immediate postoperative period, assess for pain, abdominal distention, and return of bowel sounds. If a gastrostomy tube is placed, it is often open to straight drain for a period of time postoperatively to keep the stomach empty and allow for the internal incision to heal. When bowel sounds have returned and the infant or child is stable, introduce feedings slowly (typically via the gastrostomy tube). Assess for tolerance of feedings (absence of abdominal distention or pain, minimal residual, and passage of stool). If the abdomen does become distended or the child has discomfort, open the gastrostomy tube to air to decompress the stomach. Assess the insertion site of the gastrostomy tube for redness, edema, or drainage. Keep the site clean and dry per surgeon or hospital protocol. Teach the parents how to care for the gastrostomy tube and insertion site and how to use the tube for feeding.

Promoting Family and Patient Coping

Parents can feel a great deal of anxiety. Teach the family about all aspects of GERD to help promote coping. School-age children often have reflux episodes exhibited by postprandial vomiting, which can be very embarrassing for the children. Notify the school about the medical issues related to GER to minimize the situations for the child.

PEPTIC ULCER DISEASE

Peptic ulcer disease (PUD) is a term used to describe a variety of disorders of the upper GI tract that result from the action of gastric secretions (Fig. 41.14). Mucosal inflammation and subsequent ulceration occur as a result of either a primary or a secondary factor. In children, duodenal ulcers are more common than gastric ulcers. Primary peptic ulcers are usually associated with *Helicobacter pylori,* a gram-negative organism that causes mucosal inflammation and in some cases more severe disease. *H. pylori* is found mostly in the duodenum.

Secondary peptic ulcers may occur as a result of an identifiable factor, such as excess acid production, stress, medications, or the presence of other underlying conditions. Secondary ulcers tend to be gastric in location as opposed to duodenal.

Primary PUD is more common in children over age 10. There is a higher incidence of secondary PUD in patients under age 6, though it can be found in children of all ages (Herbst, 2004).

Take NOTE!

Severe stress, such as burns or another illness necessitating critical care, can contribute to the development of a peptic ulcer in children.

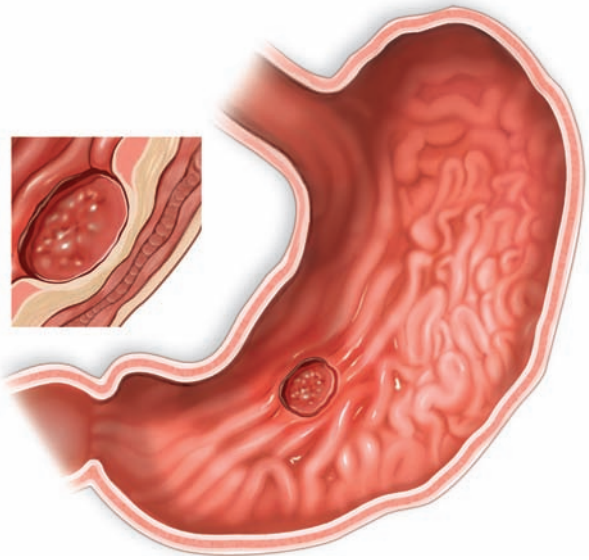

FIGURE 41.14 Peptic ulcer disease.

Therapeutic Management

PUD may be treated with antibiotics (if *H. pylori* is verified), histamine agonists, and/or proton pump inhibitors. If the child presents with a severe esophageal or gastric hemorrhage, a nasogastric tube may be placed to decompress the stomach. The patient may require intravenous infusion of a histamine H2-receptor antagonist or a proton pump inhibitor initially until the bleeding has stopped and the disease is stabilized.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1329. Assessment findings pertinent to PUD are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Abdominal pain
- GI bleeding
- Vomiting

Abdominal pain is the most common complaint of children with PUD. It is important to characterize the abdominal pain, as many other digestive disorders may mimic PUD. The pain tends to be dull and vague, mostly epigastric or periumbilical. Most often, patients with PUD have pain that worsens after meals, and the pain may wake them at night. Vomiting may be noted in preschool and school-age children.

Explore the client's current and past medical history for risk factors such as a family history of PUD or other GI diseases, or chronic salicylate or prednisone use.

▶ *Take* NOTE!

Adolescents at increased risk for the development of PUD include those who use tobacco, alcohol, and caffeine.

Physical Examination and Laboratory and Diagnostic Tests

Palpate the abdomen for the location of the pain, which is usually epigastric or periumbilical. Note the presence of blood in emesis or stools, as GI bleeding may occur (Sondheimer, 2007). Common laboratory and diagnostic studies ordered for the assessment of PUD include the following:

- Laboratory studies: to identify anemia or *H. pylori* antibodies
- Urea breath test: to identify *H. pylori* gastritis
- Upper GI series: to detect presence of ulcerations
- Upper endoscopy: the definitive diagnostic test to look for ulceration and nodularity in the upper GI tract
- Biopsies: to assess for *H. pylori*, granulomas, eosinophils, or corrosive agents to identify the primary cause of the PUD

Nursing Management

Hemodynamic stabilization should be the focus of nursing management if significant GI bleeding occurs. Once patients are stabilized and tolerating oral feeds, they may be discharged to home. Provide discharge instructions on the following topics:

- Medications
- Dietary management (especially when allergic gastroenteropathy is found)
- Safety precautions (in cases of ingested substances)
- Stressors
- Prevention of disease recurrence

CONSTIPATION AND ENCOPRESIS

Constipation is a very common problem seen in a pediatric practice, reportedly representing 3% to 5% of all pediatric outpatient visits. As many as one third of children aged 6 to 12 years experience constipation (Biggs & Dery, 2006).

Constipation is usually defined as failure to achieve complete evacuation of the lower colon. It is usually associated with difficulty in passing hard, dry stools but can sometimes be seen as small stools the size of marbles. Term newborns should pass a meconium stool within the first 24 hours of life. If this does not occur, the newborn is at risk for developing an underlying GI disorder. The bowel habits of both infants and children vary widely, so assess and treat each child on an individual basis. Breastfed infants may produce a stool with each feeding, though some will skip a few days between stools. Most bottle-fed babies will produce a stool one or two times per day, but they may go 2 to 3 days without producing a stool.

Encopresis is a term used to describe soiling of fecal contents into the underwear beyond the age of expected toilet training (4 to 5 years of age). Encopresis is often seen as a result of chronic constipation and withholding of stool. As stool is withheld in the rectum, the rectal muscle can stretch over time, and this stretching of the rectum causes fecal impactions. Patients who have a stretched rectal vault may experience diarrhea, where leakage occurs around a fecal mass. This is often an embarrassing issue that occurs with school-age children, and the child may hide his or her underwear to avoid punishment. Many psychological issues arise from chronic constipation and encopresis.

Pathophysiology

As stool passes through the colon, water is reabsorbed into the colon, resulting in a formed stool by the time it reaches the rectum. At this point, the anal sphincter relaxes to allow the passage of stool from the anus. In constipation, however, this relaxation does not occur.

Most causes of constipation are functional in nature (inorganic). Children with functional constipation usually present with this problem during the toilet-training years. Children have a painful experience during defecation, which in turn creates a fear of defecation, resulting in further withholding of stool. Organic causes of constipation rarely occur in children; however, this may be a sign of a disease such as spina bifida or sacral agenesis. The causes of pediatric constipation are discussed in Box 41.5.

Therapeutic Management

Once any organic process is ruled out as a cause for constipation, it may initially be managed with dietary manipulation such as increasing fiber and fluids. Behavior modification is necessary for most children. Children need to relearn to allow bowel evacuation when stool is present. Children with severe constipation and withholding behaviors may not benefit from dietary management and may require laxative therapy. Sometimes mechanical disimpaction is required initially, followed by the above measures.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1329. Assessment findings pertinent to constipation/encopresis are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Note the onset of symptoms as described by the parent/child. Common signs and symptoms reported during the health history may include:

- Altered stooling patterns (size, frequency, amount, color)
- Pain with defecation
- Withholding behaviors (postures to try to withhold the stool, such as crossing the legs, squatting or hiding in a corner, or "dancing")
- Complaints of abdominal pain and cramping and poor appetite
- Diarrhea leakage
- Soiling of undergarments

It is important to note the duration of the symptoms to determine an acute onset versus a chronic disorder.

Explore the client's past and current medical history for risk factors such as:

- Family history of GI disorders
- History of rectal bleeding or **anal fissures**
- Report of first meconium stool after 24 hours of age
- History of sexual abuse

An accurate dietary history as well as a history of fluid intake should be taken. Current medication or laxative use should also be explored.

Physical Examination

Physical examination of the child with constipation consists of inspection, auscultation, percussion, and palpation.

BOX 41.5 Causes of Pediatric Constipation by Age

Newborn/Infant	Toddler and Ages 2–4 Years	School Age	Adolescent	Any Age
• Meconium plug • Hirschsprung's disease • Cystic fibrosis • Congenital anorectal malformations • Pseudo-obstruction • Endocrine: hypothyroidism • Metabolic: diabetes insipidus, renal tubular acidosis • Withholding • Dietary changes	• Anal fissures • Withholding • Toilet refusal • Short-segment Hirschsprung's disease • Neurologic disorders • Spinal cord: meningomyelocele, tumors, tethered cord	• Toilet or bathroom access limited or unavailable • Limited ability to recognize physiologic cues, preoccupation with other activities • Tethered cord • Withholding	• Spinal cord injury (accidents, trauma) • Dieting • Anorexia • Pregnancy • Idiopathic slow transit constipation, particularly in females • Laxative abuse • Irritable bowel syndrome, constipation variant	• Medication side effect, dietary, postoperative state • Previous anorectal surgery • Withholding and overflow from chronic rectal distention • Relatively rapid change to sedentary state, dehydration • Hypothyroidism

Inspection
Observe the child's general appearance. Note whether the abdomen appears distended or rounded. Observe the lower back for a deep pilonidal dimple with hair tuft, which is suggestive of spina bifida occulta. Flat buttocks may be suggestive of sacral agenesis. Inspect the anus for signs of fissures or soiling. Inspect the child's underwear for stains or smears, which are indicative of soiling (Ulshen, 2004c).

Auscultation
Auscultate bowel sounds to determine the possibility of an obstruction (hypoactive or absent bowel sounds) in the child with an acute case of constipation.

Percussion
Percuss the abdomen to reveal dullness, which would indicate a fecal mass.

Palpation
Palpate the abdomen for any tenderness or masses. The nurse may assist the physician or practitioner with the performance of a rectal examination to assess for rectal tone and rectal vault size.

Laboratory and Diagnostic Tests
Laboratory and diagnostic tests are not routine with the diagnosis of functional constipation, but if an organic cause is suspected, the following laboratory and diagnostic tests would be ordered:

- Stool for occult blood: the presence of blood could indicate some other disease process
- Abdominal x-ray: large quantities of stool may be seen in the colon
- Sitz marker study: to detect colonic dysmotility
- Barium enema: to rule out a stricture or Hirschsprung's disease
- Rectal manometry: to evaluate rectal musculature dysfunction
- Rectal suction biopsy: to rule out Hirschsprung's disease

Nursing Management
Nursing management for the infant or child with constipation is aimed at educating the patient and family and promoting patient and family coping. Refer to the Nursing Care Plan on page 1336. Additional considerations are reviewed below.

Educating the Family and Patient
Teach parents how to assess for signs of constipation and withholding behaviors. Also provide guidelines on scheduling and supervising bowel habits in reconditioning the child to use the toilet regularly. Teach parents to use positive reinforcement techniques: for example, when the child produces an adequate-volume bowel movement, reward him or her with stickers, extra playtime or television time, and so on (Schmitt, 2004).

Dietary changes may help some children. High-fiber diets help to regulate bowel activity. Increasing fluid intake may also aid in bringing extra water into the bowel, thereby softening the stool. Infants and toddlers with constipation may experience constipation from formula or milk changes. Manipulating the formula or milk may result in better bowel habits.

Educate families about the importance of compliance with medication use, if medication is ordered. Parents often are very anxious about the use of these medications, but stress to them that compliance is essential. Assess for improper laxative use based on the history of stool patterns.

Many children present to their doctor with fecal impaction or partial impaction. Teach parents how to disimpact their children at home; this often requires an enema or stimulation therapy. Nursing Procedure 41.2 gives instructions on enema administration in children. Explain the procedure to the child in developmentally appropriate terms. Enema administration can be uncomfortable, but calming measures, such as distraction and praise, provide a comforting environment. After the impaction is removed, promote regular bowel habits to keep the impaction from recurring.

Promoting Patient and Family Coping
Childhood constipation can be a very stressful process for both the child and family. Behavior modification is

Nursing Procedure 41.2
ADMINISTERING AN ENEMA

1. Gather supplies (enema bag, lubricant, enema solution).
2. Wash hands and apply gloves.
3. Position the child:
   - Infant or toddler on abdomen with knees bent
   - Child or adolescent on left side with right leg flexed toward chest
4. Clamp the enema tubing, remove the cap, and apply lubricant to the tip.
5. Insert the tube into the rectum:
   - 2.5 to 4 cm (1 to 1.5 inches) in the infant
   - 5 to 7.5 cm (2 to 3 inches) in the child
6. Unclamp the tubing and administer the prescribed volume of enema solution at a rate of about 100 mL per minute. Recommended volumes:
   - 250 mL or less for the infant
   - 250 to 500 mL for the toddler or preschooler
   - 500 to 1,000 mL for the school-age child
7. Hold the child's buttocks together if needed to encourage retention of the enema for 5 to 10 minutes.

necessary for many children. To facilitate daily bowel evacuation, the child should sit on the toilet twice a day (after breakfast and dinner) for 5 to 15 minutes. Instruct the family to keep a "star" or reward chart to encourage compliance. The star should be awarded for compliance with time sitting on the toilet and should not be reserved for successful bowel movements only. Weeks to months may be required to change the stooling pattern.

Many parents seek counselors to help the entire family deal with the issues. Counseling is geared toward allaying the fears of a child who is afraid to defecate due to pain. Also, children who are older may have behavioral issues that need to be addressed. Psychological evaluation and possible behavioral therapy may need to be implemented if constipation becomes a power struggle.

▸ *Consider THIS!*

Jung Kim, 3 years old, is brought to the clinic by his parents with abdominal pain and a poor appetite. His mother states, "He cries when I put him on the toilet."

What other assessment information would you obtain?

What education and interventions may be necessary for this child and family?

HIRSCHSPRUNG'S DISEASE (CONGENITAL AGANGLIONIC MEGACOLON)

Hirschsprung's disease is the most common cause of neonatal intestinal obstruction (Fig. 41.15). The disease is most commonly characterized by constipation in newborns. This is due to a lack of ganglion cells in the bowel, which causes inadequate motility in part of the intestine. These ganglion cells can be absent from the rectosigmoid colon all the way into the small intestine. Approximately 75% of cases affect only the rectosigmoid colon (short-segment Hirschsprung's), but in 8% of the cases, total colonic involvement is seen (long-segment Hirschsprung's). The incidence is 1 in 5,000, and males are affected three times more than females. Hirschsprung's usually occurs in the absence of other associated anomalies, but there is an association with Down syndrome (Wyllie, 2004a).

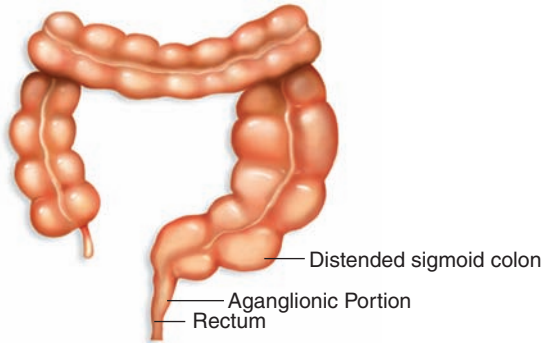

FIGURE 41.15 Enlarged megacolon of Hirschsprung's disease.

Therapeutic Management

Surgical resection of the aganglionic bowel and reanastomosis of the remaining intestine is necessary to promote proper bowel function. There are several types of surgical procedures to correct this, usually performed in stages. The surgical resection requires the child to have an ostomy to divert the stool through a stoma on the abdomen. This allows the area of the resected bowel and anastomosis to heal before it is used. The ostomy is closed at a later date.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1329. Assessment findings pertinent to Hirschsprung's are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Newborn stool patterns are a key element in recognizing this diagnosis. Assess whether the newborn passed a meconium stool: most children with Hirschsprung's do not pass a meconium stool within the first 24 to 48 hours of life. Also, newborns who required rectal stimulation to pass their first meconium stool or who passed a meconium plug should be evaluated for Hirschsprung's.

Explore the child's current and past medical history for risk factors such as a family history of Hirschsprung's or Down syndrome. Hirschsprung's may also be associated with congenital deafness, malrotation, gastric diverticulum, and intestinal atresia.

Physical Examination

Inspect and palpate the abdomen. The abdomen is typically distended, and often stool masses can be palpated in the abdomen. Perform a rectal examination to assess for rectal tone and the presence of stool in the rectum. Often with Hirschsprung's, no stool is present in the rectum, but at the end of the rectal examination, when the finger is being withdrawn, a child with Hirschsprung's may have a forceful expulsion of fecal material.

Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of Hirschsprung's include:

- Barium enema: to look for a narrowing of the intestine
- Rectal suction biopsy: to demonstrate an absence of ganglion cells (definitive diagnosis)

Nursing Management

Nursing management includes providing postoperative care, performing ostomy care, and providing patient and family education.

Providing Postoperative and Ostomy Care

Provide routine postoperative care and observe for the complication of enterocolitis (see Nursing Care Plan 41.1). Observe for the following signs and symptoms of enterocolitis:

- Fever
- Abdominal distention
- Chronic diarrhea
- Explosive stools
- Rectal bleeding
- Straining

If any of the above symptoms are noted, immediately notify the physician, maintain bowel rest, and administer intravenous fluids and antibiotics to prevent the development of shock and possibly death.

The patient with Hirschsprung's may have either a colostomy or ileostomy, depending on the extent of disease in the intestine. In either case, perform proper ostomy care to avoid skin breakdown. Accurately measure stool output to assess the child's fluid volume status.

Providing Patient and Family Education

The family may be anxious and fearful about upcoming surgeries and possible complications. Help to relieve their anxiety by providing information about the diagnosis and the stages of surgical procedures the patient will undergo. Provide postoperative teaching to educate parents on proper stoma care as well as medication management (to avoid dehydration, most Hirschsprung's patients will be prescribed medications to slow stool output). Arrange for the family to consult with a wound care nurse to help them deal with the anxieties and care of newly placed stomas. Provide education about possible postsurgical problems, emphasizing the importance of prompt medical treatment for signs of enterocolitis.

SHORT BOWEL SYNDROME

Short bowel syndrome is a clinical syndrome of nutrient malabsorption and excessive intestinal fluid and electrolyte losses that occurs following massive small intestinal loss or surgical resection. The degree of malabsorption is usually related to the extent of resection of small bowel. The most common causes of short bowel syndrome are necrotizing enterocolitis, small intestinal atresia, gastroschisis, malrotation with volvulus, and trauma to the small intestine. A child can lose as much as 75% of the small intestine without serious long-term problems, as long as the duodenum, terminal ileum, and ileocecal valve are still functioning. However, even a 25% intestinal loss can result in significant problems if the terminal ileum and ileocecal valve are not spared (Jakubik et al., 2000). If the terminal ileum is lost, vitamin B12 deficiency and bile salt malabsorption may occur. If the ileocecal valve is lost, small bowel bacterial overgrowth is likely to occur, as well as poor intestinal motility.

Therapeutic Management

The child with short bowel syndrome is at risk for chronic complications. The goals of therapeutic management are to minimize bacterial overgrowth and to maximize the child's nutritional status. Antibiotics may be used to control bacterial overgrowth. Vitamin and mineral supplementation is necessary because the small intestine is usually where fat-soluble vitamins, calcium, magnesium, and zinc are absorbed. Antidiarrheal agents such as loperamide and gastric acid-suppressive medications may be used to decrease stool output. Many children with short bowel syndrome require TPN for extended periods to achieve adequate growth. Progression to enteral feeding may occur extremely slowly, depending upon the intestine's response. Despite a markedly improved prognosis for these patients, some will not do as well and may ultimately require intestinal and liver transplantation due to irreversible liver damage from long-term use of TPN (Jakubik et al., 2000).

Nursing Assessment

Elicit the health history, noting diarrhea, which is the primary symptom of short bowel syndrome. Note past history of bowel loss or resection as noted above. Assess the child's hydration state. Inspect the stool for consistency, color, odor, and volume. Review laboratory results, particularly chemistries, to evaluate hydration status, and liver function tests, which may reveal evolving **cholestasis** secondary to long-term TPN use.

Nursing Management

Nursing management focuses on encouraging adequate nutrition and promoting effective family coping.

Encouraging Adequate Nutrition

Treatment for short bowel syndrome can be a slow and tedious process. Most patients will require TPN until they can tolerate enteral feeds without significant malabsorption. TPN is usually required for a lengthy time, so most children will require long-term intravenous access. Long-term intravenous access places the child at high risk for infection and resulting sepsis, so closely monitor for signs and symptoms of infection. Immediately report to the physician any fevers or redness or drainage at the intravenous site.

When started, enteral feeding must be administered very slowly to avoid further malabsorption. Usually the feeding is started continuously, 24 hours per day, via a feeding pump. Most patients have long-term feeding tubes, usually gastrostomy tubes. Most of these children will require special formulas to promote absorption. Assess for feeding tube residuals and abdominal distention or discomfort. Strictly monitor intake and output to avoid dehydration. Assess the stool for signs of carbohydrate malabsorption. Administer vitamin and mineral supplementation, antidiarrheals, and antibiotics as ordered. Teach the family about use of enteral feeding tubes, feeding pumps, and medication administration. (Jakubik et al., 2000).

Promoting Effective Family Coping

Children with short bowel syndrome are considered to be medically fragile for a lengthy period. There is much anxiety related to the initial bowel resection that resulted in short bowel. Long-term hospitalization is almost always required, causing parents to miss work and cutting down on the time they have to spend with other children. This can lead to even more anxiety about finances and relationships. Encourage families to become the experts on their child's needs and condition via education and participation in care. Provide teaching so that the family is better able to care for the child in an outpatient setting. Education focuses on information about TPN and central line care, enteral feedings, assessing for hydration status, and managing medications.

▶ *Take* NOTE!

Maintaining long-term central venous access for TPN in infants can present a challenge. One-piece clothing with the central venous line (CVL) tubing exiting and secured on the back of the outfit can help discourage the infant from pulling on (and subsequently dislodging) the line.

INFLAMMATORY BOWEL DISEASE

Crohn's disease and ulcerative colitis are the two major idiopathic inflammatory bowel diseases of children. The causes are unknown, but they may be due to an abnormal or uncontrolled genetically determined immunologic or inflammatory response to an environmental antigenic trigger, possibly a virus or bacterium. The features of Crohn's disease and ulcerative colitis are listed in Comparison Chart 41.2.

Therapeutic Management

Medication is used to control inflammation and symptoms. Medications commonly used include 5-aminosalicylates, antibiotics, immunomodulators, immunosuppressives, and anti-tumor necrosis antibody therapy. Dietary manipulation is also very important.

Failure to respond to medical therapy may result in surgical intervention. Many patients with ulcerative colitis eventually undergo a total proctocolectomy, with resulting ostomy, as a curative measure. Approximately 70% of Crohn's disease patients will require surgery to relieve obstruction, drain an abscess, or relieve intractable symptoms (Sondheimer, 2007).

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1329. Assessment findings pertinent to Crohn's disease and ulcerative colitis are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history include:

- Abdominal cramping
- Nighttime symptoms, including waking due to abdominal pain or urge to defecate
- Fever
- Weight loss
- Poor growth
- Delayed sexual development

Children may be reluctant or unwilling to talk about their bowel movements, so explain the importance of doing so. Assess stool pattern history, including frequency, presence of blood or mucus, and duration of symptoms.

Explore the patient's current and past medical history for risk factors, such as:

- Family history of inflammatory bowel disease
- Family history of colon cancer
- Family history of immunologic disorders

Physical Examination

Assess the child's growth using growth charts to identify any poor growth patterns. Perform a full abdominal examination, noting tenderness, masses, or fullness. Inspect the perianal area to look for skin tags or fissures, which would be highly suspicious for Crohn's disease. Assist the physician in performing a rectal examination to further assess the rectal area for blood or other lesions.

Laboratory and Diagnostic Tests

Laboratory test results may be normal. Results for children with Crohn's disease and ulcerative colitis are found in Comparison Chart 41.2. Common laboratory and diag-

COMPARISON CHART 41.2 FEATURES OF CROHN'S DISEASE AND ULCERATIVE COLITIS

Feature	Crohn's Disease	Ulcerative Colitis
Age at onset	10 to 20 years	10 to 20 years
Incidence	4 to 6 per 100,000	3 to 15 per 100,000
Area of bowel affected	Oropharynx, esophagus, and stomach, rare: small bowel only, 25% to 30%; colon and anus only, 25%; ileocolitis, 40%; diffuse disease, 5%	Total colon, 90%; proctitis, 10%
Distribution	Segmental; disease-free skip areas common	Continuous; distal to proximal
Pathology	Full-thickness, acute, and chronic inflammation; noncaseating granulomas (50%), extraintestinal fistulas, abscesses, stricture, and fibrosis may be present	Superficial, acute inflammation of mucosa with microscopic crypt abscess
X-ray findings	Segmental lesions; thickened, circular folds, cobblestone appearance of bowel wall secondary to longitudinal ulcers and transverse fissures; fixation and separation of loops; narrowed lumen; "sting sign"; fistulas	Superficial colitis; loss of haustra; shortened colon and pseudopolyps (islands of normal tissue surrounded by denuded mucosa) are late findings
Intestinal symptoms	Abdominal pain, diarrhea (usually loose with blood if colon involved), perianal disease, enteroenteric or enterocutaneous fistula, abscess, anorexia	Abdominal pain, bloody diarrhea, urgency, tenesmus
Extraintestinal symptoms:		
Arthritis/arthralgia	15%	9%
Fever	40% to 50%	40% to 50%
Stomatitis	9%	2%
Weight loss	90% (mean 5.7 kg)	68% (mean 4.1 kg)
Delayed growth and sexual development	30%	5% to 10%
Uveitis, conjunctivitis	15% (in Crohn's colitis)	4%
Sclerosing cholangitis	—	4%
Renal stones	6% (oxalate)	6% (urate)
Pyoderma gangrenosum	1% to 3%	5%
Erythema nodosum	8% to 15%	4%
Laboratory findings	High erythrocyte sedimentation rate; microcytic anemia; low serum iron and total iron-binding capacity; increased fecal protein loss; low serum albumin; antineutrophil cytoplasmic antibodies present in 10% to 20%; *Saccharomyces cervisiae* antibodies positive in 60%	High erythrocyte sedimentation rate; microcytic anemia; high white blood cell count with left shift; antineutrophil cytoplasmic antibodies present in 80%

From Sondheimer, 2007.

nostic studies ordered for the assessment of inflammatory bowel disease include:

- Radiologic studies such as upper GI series with small bowel series: may identify evidence of intestinal inflammation, estimate distribution and extent of disease, and help distinguish between Crohn's disease and ulcerative colitis
- CT scan: to rule out suspected abscess
- Colonoscopy: to diagnose inflammatory bowel disease
- Upper endoscopy: to rule out affected mucosal tissue between the mouth and anus in children with upper abdominal complaints

Nursing Management

Nursing management focuses on teaching about disease management, teaching about nutritional management, teaching about medication therapy, and promoting family and child coping.

Teaching About Disease Management

The diagnosis of Crohn's disease or ulcerative colitis can be very difficult for the patient and family to comprehend. Provide teaching about the disease process and medication therapy to help the child and family understand the seriousness of the disease. The physician may discuss surgical options during uncontrolled flare-ups, but the nurse may be the person to whom the family members or patient address their questions regarding surgery. Provide the family with information to help answer some of their questions and allay fears.

Teaching About Nutritional Management

Teach the child and family about nutritional management of the disease. For example, adequate nutrition with a high-protein and high-carbohydrate diet may be recommended; when the disease is active, lactose may be tolerated poorly; and vitamin and iron supplements will most likely be recommended. Explain that in severe cases enteral feeding tubes or TPN may be needed; this is rare but often induces remission.

Teaching About Medication Therapy

Medications are extremely important in controlling inflammatory bowel disease. Provide information about the following common medications used to control the disease:

- 5-aminosalicylates (5-ASA): used to prevent relapse (usually used in ulcerative colitis)
- Antibiotics (usually metronidazole and ciprofloxacin): typically used in patients who have perianal Crohn's disease
- Immunomodulators (usually 6-mercaptopurine [6-MP] or azathioprine): used to help maintain remission. Monitor patients for neutropenia and hepatotoxicity.
- Cyclosporine or tacrolimus: used occasionally in conjunction with 6-MP or azathioprine to maintain remission in fulminant ulcerative colitis
- Methotrexate: sometimes used to manage severe Crohn's disease
- Anti-tumor necrosis antibody therapy: widely used for children with Crohn's disease; occasionally used for children with ulcerative colitis

Promoting Family and Child Coping

Inflammatory bowel disease is a chronic and often debilitating illness. Many children with this diagnosis can lead normal lives, but frequent illnesses can cause school absences, which in turn add stress to the situation. Because schools have become much less tolerant of absences and tardiness, it may be necessary to write letters to the school explaining the frequent absences or in-school needs. Bathroom privileges should be very flexible for children during flare-ups. Children tend to be of small stature due to the illness itself and steroid use, which stunts growth; this may cause psychological issues, especially for older boys. Children with ostomies as a result of surgical resection may have self-esteem issues related to the presence and care of the ostomy. Arrange for counseling for both the child and family to discuss fears and anxiety related to a chronic disease.

CELIAC DISEASE

Celiac disease, also known as celiac sprue, is an immunologic disorder in which gluten, a product most commonly found in grains, causes damage to the small intestine. The villi of the small intestine are damaged due to the body's immunologic response to the digestion of gluten. The function of the villi is to absorb nutrients into the bloodstream. When the villi are blunted or damaged, malnutrition occurs.

Celiac disease is one of the most common chronic disorders in Europe and the U.S., affecting about 1% of the population. Increased incidence occurs in those with a family history of celiac disease and in persons with autoimmune or genetic disorders (Gelfond & Fasano, 2006).

The only current treatment for celiac disease is a strict gluten-free diet. Eliminating gluten will cause the villi of the intestines to heal and function normally, with subsequent improvement of symptoms. Even very small amounts of gluten introduced back into the diet can cause damage to the villi, so the patient must adhere to the diet throughout life.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1329. Assessment findings pertinent to celiac disease are discussed below. The child with symptoms of celiac disease often presents for evaluation by age 2.

Health History

Elicit a description of the present illness and chief complaint. The symptoms of celiac disease are very broad and are easily confused with other GI disorders. The classic symptoms of children with celiac disease are:

- Diarrhea
- **Steatorrhea**
- Constipation
- Failure to thrive or weight loss
- Abdominal distention or bloating
- Poor muscle tone
- Irritability and listlessness
- Dental disorders
- Anemia
- Delayed onset of puberty or amenorrhea
- Nutritional deficiencies

Explore the child's current and past medical history for risk factors such as Caucasian European descent and a family history of celiac disease (Allen, 2004).

Physical Examination

Assess for the typical appearance of children with celiac disease: distended abdomen, wasted buttocks, and very thin extremities (Allen, 2004) (Fig. 41.16).

Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of celiac disease include serological antibody screening and intestinal biopsy for confirmation and genetic testing. The serum antibody markers look for antibodies in the bloodstream that are specific to a patient's response to gluten. The intestinal biopsy is taken from the duodenum during an upper endoscopic procedure performed by a gastroenterologist. Pathology from the biopsy reveals partial or subtotal villous atrophy or blunting of the villi of the small intestine. A child undergoing an intestinal biopsy to confirm or rule out celiac disease must not be restricted from consuming gluten for approximately 2 months before the biopsy. However, children may become symptomatic and extremely ill with a gluten challenge; in these cases, biopsies should be obtained sooner. Genetic testing is also available for celiac disease, looking for certain human leukocyte antigen (HLA) types. This may rule out celiac disease with 99% accuracy in people who are genetically predisposed to celiac disease, obviating the need for an intestinal biopsy (Allen, 2004).

FIGURE 41.16 The child with celiac disease typically displays a distended abdomen and wasted extremities.

Nursing Management

Providing patient and family education is the key nursing role in managing children with celiac disease. The patient must adhere to a strict gluten-free diet for his or her entire life. This is often very challenging, because gluten is found in most wheat products, rye, barley, and possibly oats. Encourage the parents and child to maintain this gluten-free diet. Often, families consult a dietitian to learn about the gluten-free diet (Teaching Guidelines 41.3).

Provide educational materials and resources to the parents. Many resources are available today about celiac disease because it is becoming more commonly diagnosed (Box 41.6).

RECURRENT ABDOMINAL PAIN

Recurrent abdominal pain is a common GI complaint of children and adolescents. It affects children of all ages, and about 2% to 4% of all pediatric outpatient visits are related to recurrent abdominal pain (Saps & Li, 2006). The etiology remains unclear. The Rome Committee is a group of specialists who are focusing on the identification, management, and treatment of both adults and children with these functional GI disorders. The three categories of recurrent abdominal pain in children are functional abdominal pain, nonulcer dyspepsia, and irritable bowel syndrome. Box 41.7 outlines the Rome Committee's criteria for distinguishing different features of irritable bowel syndrome (Saps & Li, 2006).

Pathophysiology

The etiology of recurrent abdominal pain is controversial but most likely multifactorial. It is thought that the autonomic nervous system, which controls the body's response to emotions and stress, and intestinal motility are the two mechanisms. Symptoms may result from an alteration in the transmission of messages between the enteric nervous system and the central nervous system, leading to visceral hypersensitivity. Information from the GI tract is transmitted through bidirectional nerve

TEACHING GUIDELINES 41.3

Dietary Considerations in a Gluten-Free Diet

Foods Allowed	Foods To Avoid
Potato, soy, rice, or bean flour, rice bran, cornmeal, arrowroot, corn or potato starch, sago, tapioca, buckwheat, millet, flax, teff, sorghum, amaranth, quinoa	Wheat flour, rye, triticale, barley, oats, wheat germ or bran, graham, gluten, or durum flour, wheat starch, oat bran, bulgur, farina, spelt, kamut, malt extract, hydrolyzed vegetable protein
Plain, fresh, frozen, or canned vegetables made with allowed ingredients	Any creamed or breaded vegetables, canned baked beans, some French fries
All fruits and fruit juices	Some commercial fruit pie fillings and dried fruit
All milk and milk products except those made with gluten additives, aged cheese	Malted milk, flavored or frozen yogurt
All meat, poultry, fish, and shellfish, dried peas and beans, nuts, peanut butter, soybean, cold cuts, frankfurters or sausage without fillers	Any meats or poultry prepared with wheat, rye, oats, barley, gluten stabilizers, or fillers for meats, canned meats, self-basting turkey, some egg substitutes
Butter, margarine, salad dressings, sauces, soups, and desserts with allowable ingredients, sugar, honey, jelly, jam, hard candy, plain chocolate, coconut, molasses, marshmallows, meringues, pure instant or ground coffee, tea, carbonated drinks, wine (from the United States)	Commercial salad dressings, prepared soups, condiments, sauces, and seasonings made with avoided products, nondairy cream substitutes, flavored instant coffee, alcohol distilled from cereals, licorice

From NDDIC, 2007.

pathways to the brain. Most neurotransmitters are found in both the brain and the gut, suggesting the potential for integrated effects of pain modulation (Saps & Li, 2006). As different possibilities exist for the pathophysiology of recurrent abdominal pain, it is clear that there are no structural or biochemical abnormalities that are identifiable.

Therapeutic management most often focuses on increasing the child's coping skills. Some children may need dietary manipulation or medications to control diarrhea (irritable bowel syndrome).

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1329. Assessment findings pertinent to recurrent abdominal pain are discussed below.

- Celiac Disease Foundation: www.celiac.org, 818-990-2354
- Celiac Sprue Association: www.csaceliacs.org, 402-558-0600
- Gluten Intolerance Group (GIG): www.gluten.net, 206-246-6652
- R.O.C.K. (Raising Our Celiac Kids) support group: www.celiackids.com, 858-395-5421

These resources can offer information on all aspects of celiac disease, including dietary guidelines and resources for food shopping and eating in restaurants.

BOX 41.7 Rome Committee Criteria for Irritable Bowel Syndrome

12 weeks or more of the following symptoms:

- Abdominal pain relieved by defecation
- Onset of pain or discomfort associated with a change in frequency of stool
- Onset of pain or discomfort associated with a change in form of the stool
- No structural or metabolic explanation for this abdominal pain

From Saps & Li, 2006.

Health History

The diagnosis of recurrent abdominal pain is made on a symptom-based approach. Elicit a description of the present illness and chief complaint. The symptom reported mostly commonly during the health history is abdominal pain. The child may have difficulty providing a good description of the pain. It is usually periumbilical and is usually described as attacks of pain. It is uncommon for the child to wake up in the middle of the night with this type of pain. In cases of irritable bowel syndrome, the pain may be relieved by defecation. Because diet may play a large role in the symptoms, obtain a dietary history. Take a detailed medication history, because abdominal pain may be an adverse effect of some medications. Identifying social and school stressors is essential.

Physical Examination

Note the child's body positioning and facial expressions. Interactions with family members during the interview may provide more details regarding social stressors. Palpate the abdomen for tenderness.

Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of recurrent abdominal pain include:

- Complete blood count: to rule out organic causes of abdominal pain
- Erythrocyte sedimentation rate: to rule out organic causes of abdominal pain
- Urinalysis: to rule out organic causes of abdominal pain
- Complete metabolic panel (CMP): to rule out organic causes of abdominal pain
- Stool studies: to assess for routine pathogens

Nursing Management

Once the diagnosis of recurrent abdominal pain with no organic cause is made, the majority of the nursing management is focused on promoting coping skills. Often the physician performs a battery of tests to rule out organic causes, especially when patient and family anxiety is high. After these tests are complete, teach the family about the factors that exacerbate the pain and how to deal with these factors.

Diet changes may need to be implemented. High-fiber diets help with bowel regulation by keeping motility regular.

Often medications are used to relieve abdominal cramps. Antidiarrheals may be used for patients with irritable bowel syndrome that is manifested by diarrhea. Occasionally pain modulators and antidepressants are used to help block the neurotransmitters in the brain–gut connection that cause pain. Encourage compliance with the medication regimen: compliance is needed to achieve beneficial results with many of these medications.

Arrange for counseling, if necessary, for children with social stressors. Children with recurrent abdominal pain may become so debilitated that they cannot function in school, possibly requiring homebound instruction. Provide education to the school, with parental permission, regarding the child's illness and how to best deal with it. Explain that this recurrent abdominal pain is a true pain that children feel and is not "in their minds."

Hepatobiliary Disorders

Hepatobiliary disorders include pancreatitis, gallbladder disease, jaundice, biliary atresia, hepatitis, cirrhosis and portal hypertension, and liver transplantation.

PANCREATITIS

Pancreatitis is increasingly being recognized as a childhood problem. It is classified into two categories: acute and chronic. Acute pancreatitis is an acute inflammatory process that occurs within the pancreas, with variable involvement of localized tissues and remote organ systems. Most common causes of acute pancreatitis include abdominal trauma, drugs and alcohol (though probably rare in children), multisystem disease (such as inflammatory bowel disease or systemic lupus erythematosus), infections (usually viruses such as cytomegalovirus or hepatitis), congenital anomalies (ductal or pancreatic malformations), obstruction (most likely gallstones or tumors in children), or metabolic disorders. Chronic pancreatitis is defined based on the structural and/or functional permanent changes that occur in the pancreas (Werlin, 2004).

When pancreatitis is suspected, the child is placed on immediate bowel rest (NPO). Often, a nasogastric tube placed for suction will be needed to keep the stomach decompressed. Serial monitoring of serum amylase levels will determine when oral feeding may be restarted (Werlin, 2004).

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1329. Assessment findings pertinent to pancreatitis are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history include:

- Acute onset of persistent midepigastric and periumbilical abdominal pain, often with radiation to the back or chest
- Vomiting, especially after meals
- Fever

Explore the child's current and past medical history for risk factors such as:

- Cystic fibrosis
- History of gallstones
- Traumatic injury
- Family history of hereditary pancreatitis

Physical Examination

On abdominal assessment, the bowel sounds may be diminished, suggesting peritonitis. The abdomen may be tender, and distention may occur in younger children and infants. In severe cases, jaundice, ascites, or pleural effusions may occur. Bluish discoloration around the umbilicus or flanks is seen in the most severe cases of pancreatitis when hemorrhage is present.

Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment and monitoring of pancreatitis include:

- Serum amylase and/or lipase: levels three times the normal values are extremely indicative of pancreatitis (Werlin, 2004)
- Liver profile: often done to check for increased liver functions and/or bilirubin levels
- Blood work: leukocytosis is common with acute pancreatitis. Hyperglycemia and hypocalcemia may also be noted.
- C-reactive protein: levels may be elevated

Diagnostic imaging studies performed to identify malformations or cysts on the pancreas include:

- Plain abdominal x-ray: may show a localized ileus
- Ultrasound: allows direct visualization of the pancreas and the surrounding structures. This is used most frequently with children, as it is less invasive than a CT scan. A CT scan is usually used when there is difficulty in determining the cause of the pancreatitis during ultrasonography.
- Endoscopic retrograde cholangiopancreatography (ERCP): used in some children who may have ductal anomalies, usually with chronic pancreatitis, though complications from this procedure may occur.

Nursing Management

Maintain NPO status and nasogastric tube suction and patency. Administer intravenous fluids to keep the patient hydrated and correct any alterations in fluid and electrolyte balance. Pain management is crucial in children with pancreatitis. If hemorrhagic pancreatitis has occurred, blood products and/or intravenous antibiotics may be needed. Oral feedings are restarted only after the serum amylase level has returned to normal (usually in 2 to 4 days) (Werlin, 2004). Often, pancreatic enzymes are given with oral feedings if pain occurs after oral feeds are restarted.

Surgery is rarely needed in patients with pancreatitis, except in those with severe abdominal trauma or major ductal abnormalities.

Though chronic pancreatitis is rare in children, provide patient and family education regarding the signs and symptoms of recurrence and complications.

GALLBLADDER DISEASE

Cholelithiasis is the presence of stones in the gallbladder. Cholesterol stones are usually associated with hyperlipidemia, obesity, pregnancy, birth control pill use, or cystic fibrosis. They are seen more often in females than males, and increased risk occurs with age and onset of puberty. These stones occur in the gallbladder and may be found in the common bile duct. Pigment stones are found in prepubertal children and occur about equally in males and females. They are usually found in the common bile duct (associated with bacterial or parasitic infections) or the gallbladder itself (associated with hemolytic anemia or liver cirrhosis). Cholecystitis is an inflammation of the gallbladder that is caused by the chemical irritation due to the obstruction of bile flow from the gallbladder into the cystic ducts (Fig. 41.17). This inflammation is typically associated with gallstones in children. The most common complication in children with gallstone disease is pancreatitis (Suchy, 2004).

If cholelithiasis results in symptomatic cholecystitis, then surgical removal of the gallbladder (cholecystectomy) will be necessary. This is often accomplished laparoscopically.

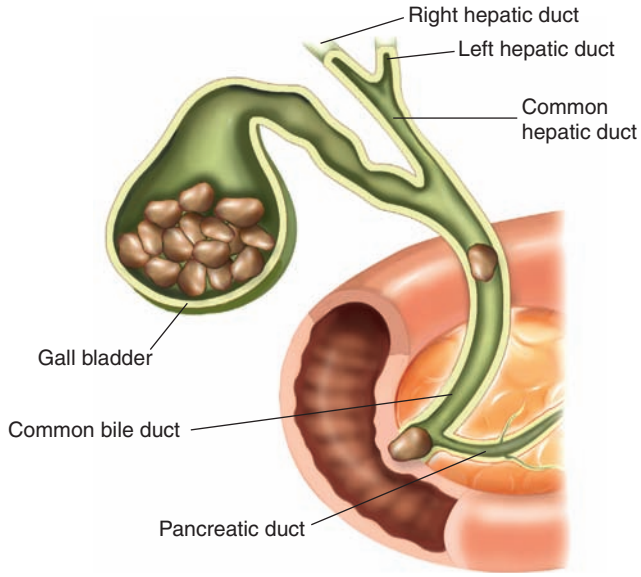

FIGURE 41.17 When gallstones block the flow of bile through the ducts, cholecystitis results.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1329. Assessment findings pertinent to gallbladder disease are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history include:

- Right upper quadrant pain, often radiating substernally or to the right shoulder
- Nausea and vomiting
- Jaundice and fever (with cholecystitis)

Document a detailed diet history as it relates to the presenting symptoms. Pain episodes usually occur after meals (postprandially), especially after the ingestion of fatty or greasy foods. Younger children may present with more nonspecific symptoms, most often due to their lack of ability to communicate their symptoms to others. Explore the patient's current and past medical history for risk factors such as chronic TPN use or sickle cell disease.

Physical Examination

Palpate the abdomen for tenderness. If cholecystitis is present, the gallbladder becomes inflamed, often to the point of causing localized tenderness upon palpation. Assess skin and sclerae color for jaundice. Note presence of fever.

Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of cholecystitis include:

- Liver function tests, bilirubin, and C-reactive protein: values may be elevated if ductal stones are present
- CBC: may reveal leukocytosis
- Amylase and lipase: may be elevated if pancreatitis is also present
- Plain abdominal x-rays: may reveal radiopaque stones
- Ultrasound of the gallbladder and surrounding structures: to assess the intraluminal contents of the gallbladder as well as any anatomic alterations
- ERCP: to rule out ductal stones
- HIDA scan: to evaluate the function of the gallbladder

Nursing Management

The child with symptomatic cholecystitis will usually be hospitalized. Administer intravenous fluids, maintain NPO status and gastric decompression, and administer pain medications. If ordered, administer intravenous antibiotics to treat clinically worsening symptoms of cholecystitis, such as persistent fever. Provide routine postoperative care after cholecystectomy is performed. Provide pre- and postoperative teaching for families of children undergoing gallbladder removal.

BILIARY ATRESIA

Biliary atresia is an absence of some or all of the major biliary ducts, resulting in obstruction of bile flow. The resultant obstruction to bile flow causes cholestasis and progressive fibrosis with end-stage cirrhosis of the liver (Balistreri, 2004). In approximately 80% of the cases, biliary atresia presents around 4 weeks of age in term, healthy infants who have resolved physiologic jaundice. In approximately 20% of cases, biliary atresia presents with persistent jaundice that never disappeared from the physiologic period. This second type of biliary atresia often is associated with other congenital anomalies, such as situs inversus, malrotation, polysplenia, and cardiovascular defects (Balistreri, 2004). The etiology of biliary atresia is unknown, but there are several theories, including infectious, autoimmune, or ischemic causes.

Therapeutic Management

If there is a high suspicion of biliary atresia, the infant will undergo exploratory laparotomy. If biliary atresia is found, a Kasai procedure (hepatoportoenterostomy) is performed to connect the bowel lumen to the bile duct remnants found at the porta hepatis. This procedure is usually successful only for infants up to 8 weeks of age, as bile flow restoration after this age is minimal. Infants who are not identified early enough or those who have failed to respond to the Kasai procedure will need to undergo liver transplantation, usually by age 2.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1329. Assessment findings pertinent to biliary atresia are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Persistent or recurring jaundice is the most common symptom reported during the health history.

Physical Examination

In the initial assessment of an infant with cholestasis of unknown origin, assess the stool character. In biliary atresia, stools will be acholic (chalky and white due to the lack of bile pigment). Note jaundice of the skin and sclerae (yellow discoloration caused by bile pigment deposition). Palpate the abdomen; the liver will feel enlarged and hardened. Splenomegaly may occur. In the absence of other congenital malformations, the infant will otherwise appear healthy.

Laboratory and Diagnostic Studies

Common laboratory and diagnostic studies ordered for the assessment of biliary atresia include:

- Serum bilirubin, alkaline phosphatase, liver enzymes, GGT: elevated
- Ultrasound: to identify anomalies
- Biliary scan: to distinguish whether the cholestasis is intrahepatic or extrahepatic
- Liver biopsy: to confirm the diagnosis (Balistreri, 2004)

Nursing Management

Nursing management of infants who have biliary atresia will focus on vitamin and caloric support. Administer fat-soluble vitamins A, D, E, and K. Special formulas containing medium-chain triglycerides are used because significant fat malabsorption occurs when cholestasis is present. Administer feedings via nasogastric tube as needed to ensure increased caloric intake. Identify infections as quickly as possible and administer intravenous antibiotics as ordered. Manage ascites with diuretics and dietary restrictions. Preoperative management before a Kasai procedure is focused on preparation for surgery; infants who have suspected biliary atresia require immediate surgery to optimize outcomes.

Parents and family members of these infants will have extreme anxiety due to the implications of the diagnosis and outcomes. Focus education on the diagnosis and postoperative care. Nursing Care Plan 41.1 gives information about routine postoperative care.

HEPATITIS

Hepatitis is an inflammation of the liver that is caused by a variety of agents, including viral infections, bacterial invasion, metabolic disorders, chemical toxicity, and trauma. The most common viral causes of hepatitis are listed in Table 41.3. Other viruses that may cause hepatitis are cytomegalovirus (CMV), Epstein-Barr virus (EBV), and adenovirus. Fulminant hepatitis is thought to be caused by a non-A, non-B, non-C virus. Children who present with fulminant hepatitis have acute massive hepatic necrosis, resulting in death without liver transplantation. The disease progresses rapidly to severe jaundice, coagu-

TABLE 41.3 Hepatitis Viruses A–E

	Hepatitis A (HAV)	Hepatitis B (HBV)	Hepatitis C (HCV)	Hepatitis D (HDV)	Hepatitis E (HEV)
Transmission route	Oral–fecal route, poor sanitation, waterborne	Sexual, intravenous drug use, blood transfusion, perinatally transmitted from mother to infant	Blood product transfusion, intravenous drug use	Same as HBV; HBV markers in serum must be present	Oral–fecal, possible contact
Incubation period	15 to 30 days	50 to 150 days	30 to 160 days	50 to 150 days	15 to 65 days
Signs and symptoms	Flu-like symptoms Preicteric phase: headache, fatigue, fever, anorexia Icteric phase: jaundice, dark urine, tender liver (right upper quadrant pain)	Some cases are asymptomatic; others present with anorexia, abdominal pain, fatigue, rash, slight fever, visible jaundice, enlarged liver.	Chronic cases usually present asymptomatically; others with flu-like symptoms, jaundice, hepatosplenomegaly	Same as HBV	Same as HAV, more severe in pregnant women
Prognosis	Rarely develops into fulminant liver failure; 95% of children recover without sequelae	Chronic disease state likely; increased risk of hepatic cancer	Many will develop chronic hepatitis and cirrhosis.	Same as HBV, but increased likelihood of chronic active hepatitis and cirrhosis	Same as HAV; high mortality in pregnant women

lopathy, elevated ammonia levels, significantly elevated liver enzyme levels (AST and ALT), and progressive coma. Autoimmune hepatitis is a chronic disorder, affecting mostly adolescent females. The clinical presentation of a child with autoimmune hepatitis includes hepatosplenomegaly, jaundice, fever, fatigue, and right upper quadrant pain.

Therapeutic Management

Acute hepatitis is treated with rest, hydration, and nutrition. Control of bleeding may also be necessary. Chronic hepatitis often eventually requires liver transplantation. Corticosteroids and immunosuppressants may be used for autoimmune hepatitis. The child with fulminant hepatitis usually requires intensive care with cardiorespiratory support. See Healthy People 2010.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1329. Assessment findings pertinent to hepatitis are discussed below. The nursing assessment for any child who presents with suspected hepatitis should be the same.

Health History

Elicit a description of the present illness and the chief complaint. Common signs and symptoms reported during the health history include:

- Jaundice
- Fever
- Fatigue
- Abdominal pain

Explore the patient's current and past medical history for risk factors such as:

- Recent foreign travel
- Sick contacts
- Medication use
- Abdominal trauma

HEALTHY PEOPLE 2010

Objective	Significance
Reduce or eliminate indigenous cases of vaccine-preventable diseases, hepatitis B (persons aged 2 to 18 years).	• Educate families about hepatitis B and its transmission. • Encourage routine infant and childhood vaccination against hepatitis A and B as recommended.
Reduce hepatitis A.	• For hepatitis A prevention, educate families about appropriate hygiene and hand washing.

- Sexual activity
- Intravenous drug use
- Blood product transfusion

Document onset of symptoms as well as all signs and symptoms the patient has been experiencing.

Physical Examination

Observe the skin for jaundice and the sclerae for icterus. Palpate the abdomen to reveal abnormal liver and spleen size or tenderness.

Laboratory and Diagnostic Studies

Common laboratory and diagnostic studies ordered for the assessment of hepatitis include:

- Liver enzymes, GGT: elevated
- PT/PTT: prolonged
- Ammonia: elevated in the presence of encephalopathy
- Autoimmune studies, such as antinuclear antibodies, anti–smooth muscle antibodies, and liver–kidney microsomal antibodies: may be used to diagnose autoimmune hepatitis
- Viral studies: to identify viral causes of hepatitis, such as hepatitis A–E antigens and antibodies, CMV and EBV
- Ultrasound: to assess liver or spleen abnormalities
- Liver biopsy: to determine the type of hepatitis and to assess for damage that has already been done to the liver

Nursing Management

Acute hepatitis requires rest, hydration, and nutrition. If the child develops vomiting, dehydration, elevated bleeding times (PT/PTT), or mental status changes (encephalopathy), hospitalization may be required. When caring for patients with infectious hepatitis, provide education about transmission and prevention, including proper hygiene, safe sexual activity, careful hand washing techniques, and blood/bodily fluid precautions.

Fulminant hepatitis treatment is aggressive and will require NPO status, nasogastric tube administration of lactulose to decrease ammonia levels that lead to encephalopathic conditions, TPN administration, vitamin K injections to help with coagulopathies, and, ultimately, liver transplantation. Fear and anxiety of the patient and parents will likely be very high. Teach the child and family about the diagnosis and what to expect during treatment. Provide immunoglobulin therapy and vaccinations to close contacts of infectious hepatitis patients.

CIRRHOSIS AND PORTAL HYPERTENSION

Cirrhosis of the liver occurs as a result of the destructive processes that occur during liver damage, leading to the

formation of nodules. These nodules can be small (micronodular [less than 3 mm]) or large (macronodular [greater than 3 mm]) and distort the vasculature of the liver, leading to further complications. Causes of cirrhosis in children include biliary malformations, alpha-1 antitrypsin deficiency, Wilson's disease, galactosemia, tyrosinemia, chronic active hepatitis, and prolonged TPN use (Sokol & Narkewicz, 2005). Major complications may exist due to cirrhosis of the liver, including portal hypertension. In portal hypertension, the blood flow to, through, or from the liver meets resistance, causing portal blood flow pressures to rise. As these pressures rise, collateral veins form between the portal and systemic venous circulations. The most significant complication of portal hypertension is GI bleeding, from shunting to submucosal veins (varices) in the stomach and esophagus. Esophageal varices may be treated with sclerotherapy during endoscopy to stop acute bleeding. Often blood product administration and vasopressive drugs are needed. In the long term, the only cure for cirrhosis is liver transplantation.

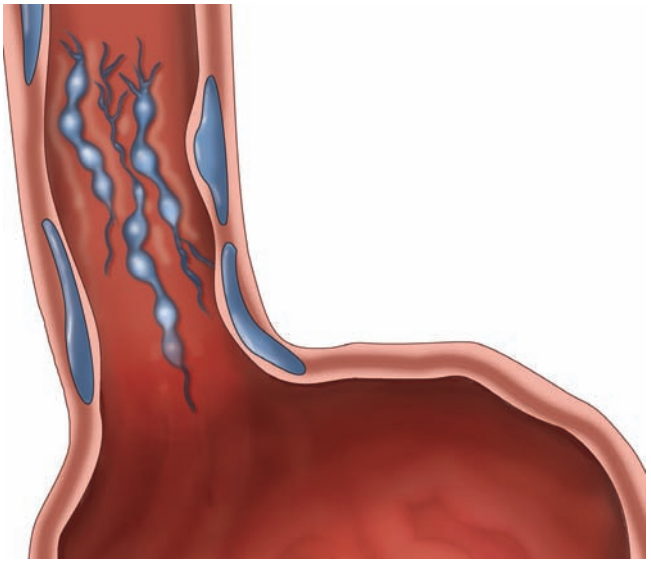

FIGURE 41.18 Esophageal varices.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1329. Assessment findings pertinent to cirrhosis and portal hypertension are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history include:

- Nausea and vomiting
- Jaundice
- Weakness
- Swelling
- Weight loss

Explore the patient's current and past medical history for risk factors such as hepatitis, cystic fibrosis, Wilson's disease, hematochromatosis, and biliary atresia. Assess the past medical history to identify possible causes for liver disease.

Physical Examination

Inspect for jaundice, ascites, spider angiomas, and palmar erythema. Gynecomastia is often seen in males. Palpate the liver; typically it is enlarged and hard, but occasionally it is small and shrunken. Evaluate mental status to determine the presence of hepatic encephalopathy.

Laboratory and Diagnostic Studies

Laboratory and diagnostic testing will be similar to that of a child with hepatitis. Common laboratory and diagnostic studies ordered for the assessment of cirrhosis or portal hypertension include:

- Liver biopsy: reveals regenerating nodules and surrounding **fibrosis**
- Upper endoscopy: reveals varices and bleeding (Fig. 41.18)

Nursing Management

Nursing management is very similar to the care of the patient with hepatitis. In cases of cirrhosis causing portal hypertension and bleeding varices, GI bleeding must be controlled. This is usually done by replacing blood loss and providing vasopressive therapy to constrict the shunted blood flow. As with all liver disorders and GI bleeding, address and manage family and patient anxiety. Be honest about the child's treatment plan and prognosis. Involve the family in the care of the child and educate them as needed.

LIVER TRANSPLANTATION

Hepatobiliary disorders that result in failure of the liver to function result in the need for liver transplantation. Liver transplantation in children has become increasingly successful in the past several years due to advances in immunosuppression, better selection of transplant candidates, and improvements in surgical techniques and postoperative care. Transplant centers now offer both cadaveric and living-related liver transplants for children. Rejection of the transplanted liver is the most significant complication. Most children will require immunosuppressive therapy for a lifetime, putting them at risk for infections.

Nursing Assessment

Many children will be admitted to a transplant center for a preoperative work-up to determine the best possible tissue and blood match for the patient. There is much anxiety among family members when a cadaveric transplant is the only possibility for survival. This puts a child on a waiting list that is prioritized based on several criteria. Because there are a limited number of pediatric liver transplant centers throughout the country, there may be many issues regarding transportation, finances, job loss, and lodging. Assess the need for social work intervention; a social worker is almost always involved with these patients. A liver transplant coordinator will assist with coordinating the care for pre- and post-transplant patients.

Nursing Management

Preoperatively, assist with the transplant work-up and teach the child and family what to expect during and after the liver transplantation. Postoperatively, the child will be in the intensive care unit for several days until he or she is stabilized from the actual surgery (see Nursing Care Plan 41.1). After the child is sent to a regular unit in the hospital, monitor the child for several days to weeks for signs and symptoms of rejection and infection, including fever, increasing liver function test results and GGT, and increasing pain, redness, and swelling at the incision site.

Patient and family education is an important element of nursing management in the post-transplant patient. Assess and reassess medication knowledge throughout the entire hospitalization, as these children usually require medications for a lifetime.

Key Concepts

- The esophagus of the young child exhibits underdeveloped muscle tone compared with the adult.
- A major difference between children and adults is the reduced stomach capacity in the child and the significantly shorter length of the small intestine (250 cm in the child vs. 600 cm in the adult).
- Infants and children have a proportionately greater amount of body water than adults, resulting in a relatively greater fluid intake requirement than adults and placing infants and children at higher risk for fluid loss as compared with adults.
- The most common result of GI illnesses in infants and children is dehydration.
- The mildly or moderately dehydrated child must be identified and receive rehydration therapy to prevent progression to hypovolemic shock.
- Rehydration is a key medical treatment for dehydration as a result of many different GI disorders. Oral rehydration is most common, but in cases requiring hospitalization intravenous fluid therapy is key.
- Promotion of adequate nutrition is another significant treatment component. The child with a chronic GI disorder may require intravenous TPN or enteral tube feedings to exhibit appropriate growth.
- Surgical intervention is necessary for many acute or congenital GI disorders, such as pyloric stenosis, omphalocele, gastroschisis, cleft lip and palate, appendicitis, Hirschsprung's disease, and intestinal malrotation.
- Abdominal ultrasound is the diagnostic test of choice when evaluating for pyloric stenosis.
- Monitoring the blood count, electrolyte levels, and liver function tests is necessary in many pediatric GI disorders.
- Histamine-2 blockers, proton pump inhibitors, and prokinetic agents are used to treat disorders in which gastric acid is a problem, such as esophagitis, GERD, and ulcers.
- Close monitoring for infection is important in children with inflammatory bowel disease, autoimmune hepatitis, or liver transplant who are being treated with immunosuppressants and/or corticosteroids.
- GI stimulants and laxatives may be necessary for treating constipation and encopresis.
- Diarrhea, vomiting, decreased oral intake, sustained high fever, diabetic ketoacidosis, and extensive burns place the infant or child at risk for the development of dehydration.
- Risk factors for vomiting include exposure to viruses, use of certain medications, and overfeeding in the infant.
- Risk factors for acute diarrhea include recent ingestion of undercooked meats, foreign travel, daycare attendance, and well water ingestion.
- Vomiting is a symptom and should be characterized in terms of volume, color, relation to meals, duration, and associated symptoms.
- Bleeding may occur as a result of a GI disorder, particularly from the intestine with Meckel's diverticulum and from esophageal varices with portal hypertension.
- Acute GI disorders are those that usually have a rapid onset and a short course, which at times may be severe. Examples include dehydration, vomiting, diarrhea, hypertrophic pyloric stenosis, and appendicitis.
- Chronic GI disorders are those that are long lasting or recur over time. Examples include constipation, GER, inflammatory bowel disease, recurrent abdominal pain, and failure to thrive.
- Right lower quadrant pain and rebound tenderness of the abdomen found on physical examination are telltale signs of appendicitis, which is considered a surgical emergency.
- Bilious vomiting is the main symptom of conditions resulting in bowel obstruction, such as malrotation with volvulus.
- The focus of nursing management of the child with diarrhea or vomiting is restoring proper fluid and

electrolyte balance through oral rehydration therapy or intravenous fluids if necessary.

- Reduction of inguinal and umbilical hernias should be attempted; if reduction of the hernia is impossible, immediately notify the physician.
- Small, frequent, and thickened feedings and proper positioning after feedings are key elements in the treatment of GER.
- A crucial nursing intervention related to cleft lip and palate repair is protection of the surgical site while it is healing.
- Palpation of the abdomen should be the last part of the physical examination of an infant or child.
- A key element of nursing care for the child with a GI disorder is promotion of appropriate bowel elimination.
- Maximizing nutritional status is a critical nursing function for the child with a GI disorder.
- For the child who has undergone surgical repair or correction of a GI disorder, promoting effective breathing patterns and managing pain are important nursing goals.
- Counseling families about how to manage the child with vomiting or diarrhea at home, including oral rehydration therapy, is a key component of patient/family education.
- Education of the child and family regarding the importance of medication compliance for management of inflammatory bowel disease is critical.
- Behavioral therapy and counseling may be necessary for children who have functional constipation and stool withholding.
- The child or adolescent with ineffective bowel control, poor growth, or an ostomy may have poor self-esteem and body image.

Chapter Worksheet

Multiple Choice Questions

1. A mother brings her 6-month-old infant to the clinic. The child has been vomiting since early morning and has had diarrhea since the day before. His temperature is 38° C, pulse 140, and respiratory rate 38. He has lost 6 ounces since his well-child visit 4 days ago. He cries before passing a bowel movement. He will not breastfeed today. What is the priority nursing diagnosis?
   a. Thermoregulation alteration
   b. Pain (abdominal) related to diarrhea
   c. Fluid volume deficit related to excessive losses and inadequate intake
   d. Alteration in nutrition, less than body requirements, related to decreased oral intake
2. A child presents with a 2-day history of fever, abdominal pain, occasional vomiting, and decreased oral intake. Which finding would the nurse prioritize for immediate reporting to the physician?
   a. Temperature 101.9° F
   b. Rebound tenderness and abdominal guarding
   c. Parents will be leaving the child alone in the hospital
   d. Child can tolerate only sips of fluid without nausea
3. A 3-day-old infant presenting with physiologic jaundice is hospitalized and placed under phototherapy. Which response indicates to the nurse that the parent needs more teaching?
   a. "My infant is at risk for dehydration."
   b. "My infant needs to stay under the lights, except during feeding time."
   c. "My infant can continue to breastfeed during this time."
   d. "My infant has a serious liver disease."
4. A 3-month-old infant presents with a history of vomiting after feeding. The plan for the infant is to rule out GERD. What information from the history would lead the nurse to believe that this infant may need further intervention?
   a. Poor weight gain
   b. Has small "spits" after feeding
   c. Sleeps through the night
   d. Is difficult to burp
5. The nurse is caring for a child who has had diarrhea and vomiting for the past several days. What is the priority nursing assessment?
   a. Determine the child's weight.
   b. Ask if the family has traveled outside of the country.
   c. Assess circulation and perfusion.
   d. Send a stool specimen to the lab.

Critical Thinking Exercises

1. A 6-month-old baby is brought to the pediatrician's office with a history of diarrhea. She has had six watery stools in the past 18 hours. She is vomiting her formula. Her mother states that she has had no fever.
   a. Upon completion of the history and physical examination, what signs and symptoms would you expect to find that would indicate that the baby is experiencing mild dehydration?
   b. What is the priority nursing diagnosis for this infant?
   c. Identify a plan for this nursing diagnosis; include a teaching plan for the mother.
2. A 14-kg child with moderate dehydration has received two boluses of normal saline in the emergency room prior to being admitted to the pediatric nursing unit. The physician orders D5 ½ NS @ 1½ maintenance.
   a. What would the intravenous fluid rate be?
   b. What will the nurse assess for to determine whether the child is becoming overhydrated?
3. An infant requires a temporary colostomy. What discharge instructions would you provide to the parents about how to take care of the colostomy and when to call their health care provider?

Study Activities

1. In the clinical setting, compare the growth records of a child with celiac disease to those of a similar-aged child without disease.
2. While caring for children in the clinical setting, compare and contrast the medical history, signs and symptoms of illness, and prescribed treatment for a child with Crohn's disease and one with ulcerative colitis.
3. In the clinical setting, observe the behavioral responses of an infant or young child with inorganic failure to thrive.

CHAPTER 42

Nursing Care of the Child With a Genitourinary Disorder

KEY TERMS

amenorrhea
anasarca
anuria
azotemia
bacteriuria
dysmenorrhea
enuresis
hematuria
hyperlipidemia
menorrhagia
oliguria
proteinuria
sepsis
urgency
urinary frequency

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Compare anatomic and physiologic differences of the genitourinary system in infants and children versus adults.
2. Describe nursing care related to common laboratory and diagnostic testing used in the medical diagnosis of pediatric genitourinary conditions.
3. Distinguish genitourinary disorders common in infants, children, and adolescents.
4. Identify appropriate nursing assessments and interventions related to medications and treatments for pediatric genitourinary disorders.
5. Develop an individualized nursing care plan for the child with a genitourinary disorder.
6. Describe the psychosocial impact of chronic genitourinary disorders on children.
7. Devise a nutrition plan for the child with renal insufficiency.
8. Develop patient/family teaching plans for the child with a genitourinary disorder.

Corey Bond, 5 years old, is brought to the clinic by her mother. She presents with fever and lethargy for the past 24 hours. Her mother states, "Corey has had a few accidents in her pants over the past few days, which is unusual for her. She also has been getting up at night more often to use the bathroom."

Wow

A child's essential bodily processes of elimination can be a major event of wonder and creative accomplishment.

Genitourinary (GU) disorders in children and adolescents may occur as a result of abnormalities in fetal development, infectious processes, trauma, neurologic deficit, genetic influences, or other causes. Congenital disorders account for a large proportion of GU disorders in infants, while enuresis and urinary tract infection (UTI) also occur in a significant number of children. Some of the disorders directly involve the kidney from the outset, while others involve other parts of the urinary tract and may have a long-term effect on the kidneys and renal function, particularly if left untreated or treated inadequately. Disorders affecting the reproductive organs often require early diagnosis and management to preserve future reproductive capabilities.

Nurses must be knowledgeable about pediatric GU conditions to provide prompt recognition, nursing care, education, and support to children and their families. Though some disorders are acute and resolve quickly, many have a long-term effect on quality of life and will require more intense, extended support.

Management of acute or common pediatric GU disorders may be provided in the pediatric or family practice outpatient setting, while specialists such as pediatric nephrologists or urologists usually manage chronic involved GU disorders.

Variations in Pediatric Anatomy and Physiology

Though all of the urinary tract and reproductive organs are present at birth, their functioning is immature initially. Many pediatric GU disorders are congenital (present at birth). External GU malformations are easily identified at birth, but internal structural defects may not be identified until later in infancy or childhood when symptoms or complications arise. In children, chronic kidney disease is most often the result of congenital structural defects or infectious, inflammatory, or immune processes that damage the kidney, whereas in adults it usually results from hypertension or diabetes. The infant or child is at increased risk for the development of certain GU disorders because of the anatomical and physiological differences between children and adults.

Urinary Concentration

Blood flow through the kidneys (glomerular filtration rate [GFR]) is slower in the infant and young toddler compared with the adult. The kidney is less able to concentrate urine and reabsorb amino acids, placing the infant and young toddler at increased risk for dehydration during times when fluid loss or decreased fluid intake occurs. The normal range for serum blood urea nitrogen (BUN) and creatinine of the healthy infant or young toddler is usually less than the older child's or adult's. The renal system usually reaches functional maturity at around 2 years of age.

Structural Differences

The kidney is large in relation to the size of the abdomen until the child reaches adolescence. Due to this increased size, the kidneys of the child are less well protected from injury by the ribs and fat padding than they are in the adult. The urethra is naturally shorter in all ages of females than in males, placing them at increased risk for the entrance of bacteria into the bladder via the urethra. In the female infant or young child, this risk is compounded by the physical proximity of the urethral opening to the rectum. The young male's urethra is much shorter than the adult male's, placing the male infant or young child at increased risk of urinary tract infection compared with the adult male.

Urine Output

Bladder capacity is about 30 mL in the newborn; it increases to the usual adult capacity of about 270 mL by 1 year of age. The expected urine output in the infant and child is 0.5 to 2 mL/kg/hour, with the average 1-year-old voiding about 400 to 500 mL per day. The average urine output for a teenager is about 800 to 1,400 mL per day. The infant and toddler may void as often as 9 or 10 times per day. By age 3 the average number of voids per day is the same as the adult's (three to eight).

Reproductive Organ Maturity

The reproductive organs are also immature at birth. The gonads are not mature until adolescence in most children. The hormonal changes that occur with puberty account for some of the reproductive concerns, particularly for female adolescents.

Common Medical Treatments

A variety of medications as well as other medical treatments and surgical procedures are used to treat GU problems in children. Most of these treatments will require a physician's order when the child is in the hospital. The most common treatments and medications are listed in Common Medical Treatments 42.1 and Drug Guide 42.1. The nurse caring for the child with a GU disorder should be familiar with what the procedures are, how the treatments and medications work, and common nursing implications related to use of these modalities.

Nursing Process Overview for the Child With a GU Disorder

Care of the child with a GU disorder includes assessment, nursing diagnosis, planning, interventions, and evaluation. There are a number of general concepts related to the nursing process that may be applied to GU disorders. From a

COMMON MEDICAL TREATMENTS 42.1 GENITOURINARY DISORDERS

Treatment	Explanation	Indications	Nursing Implications
Urinary diversion	Surgical diversion of ureters to the abdominal wall. Continent diversion uses a piece of intestine to create a bladder that can be catheterized. Noncontinent diversion involves a stoma on the abdominal wall that requires use of an ostomy pouch.	Any situation in which the bladder needs to be removed or does not function correctly (bladder exstrophy or prune belly)	Meticulous skin care is necessary to prevent breakdown around stoma. Teach families how to care for ostomy pouch or how to catheterize continent stoma. Expect mucus in urine if intestine is used for urinary reservoir. Monitor for signs of urinary tract infection.
Foley catheter	An indwelling urinary catheter stays in place by means of an inflated balloon.	Usually used only during the postoperative period	Monitor for urethral drainage or irritation. Keep area clean and dry. Monitor color, consistency, clarity, and amount of urine in drainage bag. Monitor for infection, checking results of urinalysis and urine cultures.
Ureteral stent	A thin catheter temporarily placed in the ureter to drain urine. Removed via cystoscopy when it is time for discontinuation.	Urinary tract anomalies	Monitor urine output carefully. Check for bleeding postoperatively.
Nephrostomy tube	Tube placed directly into the kidney to drain urine externally to a bag	Urinary tract anomalies	Monitor urine output carefully.
Suprapubic tube	Catheter placed in the bladder via the abdominal wall above the symphysis pubis	Postoperative urine drainage with reconstructive surgeries	Monitor for blood in urine, adequate urine output. Minimize manipulation of suprapubic tube to avoid triggering bladder spasms.
Vesicostomy	Stoma in the abdominal wall to the bladder	Urinary tract anomalies, neurogenic bladder	Constant urine drainage requires diaper use. Monitor urine output. Assess skin around stoma for breakdown.
Appendicovesicostomy (Mitrofanoff procedure)	Uses appendix to create a stoma on the abdominal wall that allows for catheterization of the bladder	Urinary tract anomalies, neurogenic bladder	Allows for urinary continence, which improves the child's self-esteem. Teach family and child how to catheterize stoma.
Bladder augmentation	Uses a piece of stomach or intestine to enlarge bladder capacity	Decreased bladder capacity	Since a portion of the GI tract is used, urine is often mucus-like.

general understanding of the care involved for a child with urinary, renal, or reproductive dysfunction, the nurse can then individualize the care based on client specifics.

Remember Corey, the 5-year-old with fever and lethargy? What additional health history and physical examination assessment information should you obtain?

Assessment

Assessment of urinary tract, renal, or reproductive dysfunction includes health history, physical examination, and laboratory and diagnostic testing.

Health History

The health history comprises past medical history, including the mother's pregnancy history, family history,

DRUG GUIDE 42.1 Common Drugs for GU Disorders

Medication	Action/Indication	Nursing Implications
Anticholinergic agents (oxybutynin, propantheline bromide, belladonna & opium suppository)	Cause smooth muscle relaxation of the bladder, used for urinary tract spasms or contractions related to surgical procedure or use of catheters. Control of nocturnal enuresis.	Increase fluid intake (limit to during the day in the child with nocturnal enuresis). Avoid use in febrile patient.
Antibiotics (oral, parenteral)	Kill bacteria or arrest their growth. Used for urinary tract infection.	Check for antibiotic allergies. Should be given as prescribed for the length of time indicated.
Desmopressin (DDAVP)	Antidiuretic hormone effects by causing renal tubule to absorb more water, decreasing volume of urine in children with nocturnal enuresis.	Nasal spray may cause nasal irritation, nausea, flushing, or headache. Administer at bedtime; alternate nares. Associated with a high relapse rate.
Human chorionic gonadotropin (hCG)	Stimulates production of gonadal steroids to precipitate testicular descent.	Monitor for signs of precocious puberty if used long term.
Corticosteroids	Anti-inflammatory and immunosuppressive action to induce remission and promote diuresis in nephrotic syndrome. High-dose intravenous therapy used when nephrotic syndrome is resistant to conventional doses.	Administer with food to decrease GI upset. May mask signs of infection. Do not stop treatment abruptly, or acute adrenal insufficiency may occur. Monitor for Cushing syndrome. Doses may be tapered over time. Monitor for hypertension during infusion.
Cytotoxic drugs (cyclophosphamide [Cytoxan] and chlorambucil [Leukeran])	Interfere with normal function of DNA by alkylation. Used to induce prolonged remission in nephrotic syndrome.	Causes bone marrow suppression. Monitor for signs of infection. Cyclophosphamide: administer in the morning; provide adequate hydration; have child void frequently during and after infusion to decrease risk of hemorrhagic cystitis. Chlorambucil: administer with nonspicy, non-acidic foods; rarely seizures occur.
Immunosuppressant drugs (cyclosporine A [CyA], azathioprine, tacrolimus, mycophenolate)	Cause immune suppression to prevent rejection of renal transplants. CyA and tacrolimus may be used for steroid-dependent nephrotic syndrome.	Monitor complete blood count, serum creatinine, potassium, and magnesium. Monitor blood pressure and observe for signs of infection. Blood levels should be drawn prior to morning dose. CyA: do not give with grapefruit juice. Azathioprine and mycophenolate: give on empty stomach; do not open capsule or crush tablet. Tacrolimus: give on empty stomach, assess for development of hyperglycemia. Relapse of nephrotic syndrome may occur after withdrawal of CyA or tacrolimus therapy.
Muromonab-CD3 (Orthoclone OKT3)	Removal of all CD3 molecules from T-lymphocyte surface so it has inability to act . Used for treatment of acute renal transplant rejection.	Monitor for development of pulmonary edema. First-dose effect may cause fever, chills, chest tightness, wheezing, nausea, and vomiting.

Medication	Action/Indication	Nursing Implications
Angiotensin-converting enzyme (ACE) inhibitors (captopril, enalapril)	Potent vasoconstrictor, prevents conversion of angiotensin I to angiotensin II. Used to treat renal causes of hypertension.	Monitor blood pressure frequently. May cause cough, hyperkalemia. Captopril: administer on empty stomach. Enalapril: administer without regard to food.
Imipramine (Tofranil) (tricyclic antidepressant)	Increases the synaptic concentration of serotonin and/or norepinephrine. Treatment of enuresis.	Monitor for urinary retention. May cause decreased appetite.
Diuretics: furosemide (Lasix), hydrochlorothiazide (HCTZ)	Inhibits resorption of sodium and chloride leading to increased excretion of water and electrolytes. Used in nephrotic syndrome, acute glomerulonephritis, hemolytic-uremic syndrome or other instances of fluid overload with renal sufficiency.	Administer with food or milk to decrease GI upset. Monitor blood pressure, renal function, and electrolytes (particularly potassium). May cause photosensitivity.
Vasodilators: hydralazine (Apresoline), minoxidil	Direct vasodilation of arterioles, resulting in decreased systemic resistance. Used to treat renal causes of hypertension.	May cause fluid retention. Hydralazine: administer with food. Monitor heart rate and blood pressure (closely with intravenous use). Minoxidil: may be administered without regard to food. May cause dizziness.
Calcium channel blocker: nifedipine (Procardia)	Prevents calcium from entering voltage-sensitive channels, resulting in coronary vasodilation. Used to treat renal causes of hypertension.	Administer with food; avoid grapefruit juice. Insoluble shell of extended-release tablet may pass in stool. Use caution when administering liquid-filled capsule sublingually or by bite and swallow method, as significant hypotension may occur.
Albumin (intravenous)	Increases intravascular oncotic pressure, resulting in movement of fluid from interstitial to intravascular space. Indicated for fluid volume excess associated with nephrotic syndrome.	May require a filter depending upon brand used. Rapid infusion can result in vascular overload. Monitor vital signs; observe for pulmonary edema and cardiac failure.

and history of present illness (when the symptoms started and how they have progressed), as well as medications and treatments used at home. The past medical history may be significant for maternal polyhydramnios, oligohydramnios, diabetes, hypertension, or alcohol or cocaine ingestion. Neonatal history may include the presence of a single umbilical artery or an abdominal mass, chromosome abnormality, or congenital malformation. Document past medical history of UTI or other problems with the GU tract. Family history may be significant for renal disease or uropathology, chronic UTIs, renal calculi, or a history of parental enuresis. Determine age of successful toilet training, pattern of incontinent episodes (having "accidents"), and toileting hygiene self-care routines. Note myelomeningocele or other spinal disturbance that may affect the child's ability to urinate. Note previous urologic surgeries or ongoing renal interventions (e.g., dialysis). For the adolescent girl, obtain a thorough menstrual history, including sexual behavior and pregnancy history.

When determining the history of the present illness, inquire about the following:

- Burning on urination
- Changes in voiding patterns
- Foul-smelling urine
- Vaginal or urethral discharge
- Genital pain, irritation, or discomfort
- Blood in the urine
- Edema
- Masses in the groin, scrotum, or abdomen
- Flank or abdominal pain

- Cramps
- Nausea and/or vomiting
- Poor growth
- Weight gain
- Fever
- Infectious exposure (particularly streptococcus A or *Escherichia coli*)
- Trauma

Record medications used for acute or chronic conditions, or for contraception.

Physical Examination

Physical examination of the GU system includes inspection and observation, auscultation, percussion, and palpation.

Inspection and Observation

Observe the child's general appearance, noting growth retardation or unusual weight gain. Inspect the skin for presence of pruritus, edema (generalized or periorbital), or bruising. Note pallor of the skin or dysmorphic features (associated with genetic conditions). Document presence of lethargy, fatigue, rapid respirations, confusion, or developmental delay. Observe the external genitalia area for infant diaper rash, constant urine dribble, displaced urethral opening, reddened urethral opening, or discharge. In females note vaginal irritation or labial fusion. In males observe the scrotal sac for enlargement or discoloration. Note the condition of a urinary stoma or diversion if present. With the child lying flat, observe the abdomen for distention, ascites, or slack abdominal musculature.

Auscultation

Listen carefully to heart sounds, as a flow murmur may be present in the anemic child with a renal disorder. Noted elevated heart rate. Auscultate blood pressure with the appropriate-size cuff, noting elevation or depression. In the edematous child, carefully auscultate the lungs, noting presence of adventitious sounds. Note absence of bowel sounds, as this may indicate peritonitis. In the child who receives chronic hemodialysis, auscultate the fistula for presence of a bruit (desired normal finding).

▶ *Take* NOTE!

Use the bell of the stethoscope when auscultating the infant's or child's blood pressure so that you can hear the softer Korotkoff sounds more accurately.

Percussion

Percuss the abdomen. Note unusual dullness or flatness (dullness is usually heard over the spleen at the right costal margin, over the kidneys, and 1 to 3 cm below the left costal margin). A full bladder may yield dullness above the symphysis pubis.

Palpation

Palpate the abdomen. Note presence of palpable kidneys (indicating enlargement or mass, as they are usually difficult to palpate in the older infant or child). Note presence of abdominal masses or a distended bladder. Document tenderness to palpation or along the costovertebral angle. Palpate the scrotum for presence of descended testicles, masses, or other abnormalities. Note whether the foreskin, if present, can be retracted. In the child who receives chronic hemodialysis, palpate the fistula or graft for presence of a thrill (desired normal finding).

Laboratory and Diagnostic Testing

Common Laboratory and Diagnostic Tests 42.1 offers an explanation of the most commonly used laboratory and diagnostic tests used for a child suspected of having a GU disorder. The test results can help the physician to diagnose the disorder or to determine treatment. Laboratory or non-nursing personnel obtain some of the tests, while the nurse might obtain others. In either instance the nurse should be familiar with how the tests are obtained, what they are used for, and normal versus abnormal results. This knowledge will also be necessary when providing patient and family education related to the tests and results.

Urine specimens may be collected using a variety of different methods in infants and children. Suprapubic aspiration is a useful method for obtaining a sterile urine specimen from the neonate or young infant. A sterile needle is inserted into the bladder through the anterior wall of the abdomen and the urine is then aspirated. This method is generally performed by the physician or advanced practitioner. Infants and toddlers who are not toilet trained may require a urine bag for urine collection. A sterile urine bag is required for a urine culture, a clean bag for routine urinalysis. A 24-hour urine-collection bag is also available. Nursing Procedure 42.1 gives details on the use of the urine bag.

Sterile urinary catheterization is performed like that in adults. The size of the catheter varies depending on the size of the child. If a small urinary catheter is not available, a sterile 5 French or 8 French feeding tube works well.

▶ *Take* NOTE!

Use familiar terms such as "pee-pee," "tinkle," or "potty" to explain to the child what is needed and to gain his or her cooperation.

COMMON LABORATORY AND DIAGNOSTIC TESTS 42.1
GENITOURINARY DISORDERS

Test	Explanation	Indication	Nursing Implications
Complete blood count	Evaluate hemoglobin and hematocrit, white blood cell count, and platelet count	Any condition in which anemia, infection, or thrombocytopenia is suspected	Normal values vary according to age and gender. White blood cell count differential is helpful in evaluating source of infection.
Blood urea nitrogen (BUN) (serum)	Indirect measurement of renal function and glomerular filtration in the presence of adequate liver function	Nephrotic syndrome, hemolytic-uremic syndrome, renal failure, acute glomerulonephritis or other renal diseases	BUN may be elevated with high-protein diet or dehydration, may be decreased with overhydration or malnutrition.
Creatinine (serum)	A more direct measurement of renal function, only minimally affected by liver function. Generally, doubling of the creatinine level is suggestive of a 50% reduction in glomerular filtration rate.	Used to diagnose impaired renal function	A diet high in meat may cause a transient though not pronounced increase in creatinine. There are also slight diurnal variations in levels. Draw at same time each day if serial evaluations are ordered.
Creatinine clearance (urine and serum)	A 24-hour urine collection is evaluated for the presence of creatinine, then compared with the serum creatinine level to determine creatinine clearance.	Used to diagnose impaired renal function	Discard the first void and then begin the 24-hour urine collection. Keep the specimen on ice during the collection period. Collect ALL urine passed in the 24-hour period. Ensure that a venous blood sample is drawn during the 24-hour period. The urine specimen should be sent promptly to the laboratory at the end of the 24-hour period.
Potassium (serum)	Measures the concentration of potassium in the blood	Any suspected renal disease; followed routinely in renal failure	Avoid hemolysis and allowing child to open and close the hand with a tourniquet in place, as these can cause elevation in potassium levels. Evaluate the child with increased or decreased potassium levels for cardiac arrhythmias. Immediately notify physician of critically high potassium levels.
Total protein, globulin, albumin (serum)	Protein electrophoresis separates the various components into zones according to their electrical charge.	Used to diagnose, evaluate, and monitor chronic renal disease	Significantly low levels of albumin contribute to extent of edema, as albumin is necessary in the blood to maintain colloidal osmotic pressure.
Calcium (serum)	Measurement of calcium level in the blood; half of all calcium is protein-bound, so the level will decrease with hypoalbuminemia.	Renal diseases associated with hypoalbuminemia and edema	Avoid prolonged tourniquet use during blood draw, as this may falsely increase the calcium level.

(continued)

COMMON LABORATORY AND DIAGNOSTIC TESTS 42.1
GENITOURINARY DISORDERS (continued)

Test	Explanation	Indication	Nursing Implications
Phosphorus (serum)	Measurement of phosphate level in the blood. Phosphorus levels are inversely related to calcium levels (they increase when calcium levels decrease).	Renal disease, ongoing monitoring, particularly in the patient with hypocalcemia	Child should be NPO past midnight prior to the morning of the blood draw. Avoid hemolysis, as it can falsely elevate the phosphate level.
Urinalysis (urine)	Evaluates color, pH, specific gravity, and odor of urine. Also assesses for presence of protein, glucose, ketones, blood, leukocyte esterase, red and white blood cells, bacteria, crystals, and casts.	Reveals preliminary information about the urinary tract. Useful in children with fever, dysuria, flank pain, urgency, or hematuria. Proteinuria may be noted in renal disorders.	Be aware of the many drugs affecting urine color and notify laboratory if child is taking one. Notify laboratory if female is menstruating. Refrigerate specimen if not processed promptly. While proteinuria may occur with various renal disorders, it may also occur as either transient or orthostatic proteinuria, both of which are benign events.
Cystoscopy	Endoscopic visualization of the urethra and bladder	Evaluate hematuria, recurrent urinary tract infection; determine ureteral reflux; measure bladder capacity	Encourage fluids. Monitor vital signs. Child may feel burning with voiding after procedure. Pink tinge to urine is common after procedure.
Urine culture and sensitivity	Urine is plated in the laboratory and evaluated every day for the presence of bacteria. A final report is usually issued after 48 to 72 hours. Sensitivity testing is performed to determine the best choice of antibiotic.	Used to diagnose urinary tract infection	Obtain culture specimen prior to starting antibiotics if at all possible. Avoid contamination of the specimen with stool. May be obtained by catheterization, clean-catch specimen, or sterile U-bag. In some institutions, suprapubic tap is performed in neonates and young infants by the physician or nurse practitioner.
Urodynamic studies	Measure the urine flow during micturition via a urine flow meter	Dysfunctional voiding	The child must have a full bladder. The child then urinates into the urine flow meter. There is no discomfort associated with the test.
Voiding cystourethrogram (VCUG)	The bladder is filled with contrast material via catheterization. Fluoroscopy is performed to demonstrate filling of the bladder and collapsing after emptying.	Hematuria, urinary tract infections, vesicoureteral reflux, suspected structural anomalies	Just prior to the test, insert the Foley catheter. Ensure that the adolescent female patient is not pregnant. After the test, encourage the child to drink fluids to prevent bacterial accumulation and aid in dye elimination.
Intravenous pyelogram (IVP)	Radiopaque contrast material is injected intravenously and filtered by the kidneys. X-ray films are obtained at set intervals to show pas-	Urinary outlet obstruction, hematuria, trauma to the renal system, suspected kidney tumor	Contraindicated in children allergic to shellfish or iodine. If the dye infiltrates at the intravenous site, hyaluronidase (Wydase) may be used to

Test	Explanation	Indication	Nursing Implications
	sage of the dye through the kidneys, ureters, and bladder.		speed absorption of the iodine. Ensure adequate hydration before and after the test. Some institutions require enema or laxative evacuation of the bowel prior to the study to ensure adequate visualization of the urinary tract.
Renal biopsy	Usually a percutaneous specimen is obtained by inserting a needle through the skin and into the kidney. The sample of kidney tissue obtained is then microscopically examined.	Diagnosis of renal disease or assessment of renal transplant rejection	After the biopsy, carefully assess for signs or symptoms of bleeding: increased heart rate, pale color, flank pain or backache, shoulder pain, lightheadedness. Inspect urine for gross hematuria. Child will be on bed rest, preferably supine for 24 hours.
Renal ultrasound	Reflected sound waves allow visualization of the kidneys, ureters, and bladder.	Useful in determining kidney size (as with hydronephrosis and polycystic kidney), presence of cysts or tumors, or rejection of kidney transplant	No fasting is required prior to the procedure. Does not require contrast material. The child should feel no discomfort during the ultrasound.

Nursing Diagnoses and Related Interventions

Upon completion of a thorough assessment, the nurse might identify several nursing diagnoses, such as:

- Impaired urinary elimination
- Fluid volume excess
- Imbalanced nutrition, less (or more) than body requirements
- Risk for infection
- Deficient knowledge of the child or family
- Urinary retention
- Activity intolerance
- Interrupted family process
- Disturbed body image

After completing an assessment of Corey, you note the following: foul-smelling urine, abdominal tenderness, redness in her perineal area, and slightly blood-tinged, cloudy urine. Based on these assessment findings, what would your top three nursing diagnoses be for Corey?

Nursing goals, interventions, and evaluation for the child with a GU disorder are based on the nursing diagnoses. Nursing Care Plan 22.1 can be used as a guide in planning nursing care for the child with a GU disorder. The care plan overview includes nursing diagnoses and interventions for urinary tract disorders as well as genital (or reproductive system) disorders. It should be individualized based on the patient's symptoms and needs. Refer to Chapter 35 for detailed information about pain management. Additional information will be included later in the chapter as it relates to specific disorders.

Based on your top three nursing diagnoses for Corey, describe appropriate nursing interventions.

Urinary Tract and Renal Disorders

The urinary tract and renal disorders discussed below include structural disorders, UTI, enuresis, and acquired disorders that result in altered renal function.

STRUCTURAL DISORDERS

Numerous urologic conditions occur as a result of altered fetal development. Many of these defects are apparent at birth, yet some are not recognized until later in infancy or childhood.

Nursing Procedure 42.1

Applying the Urine Bag

1. Cleanse the perineal area well and pat dry (Fig. 1). If a culture is to be obtained, cleanse the genital area with povidone–iodine (Betadine) or per institutional protocol.
2. Apply benzoin around the scrotum or the vulvar area to aid with urine bag adhesion.
3. Allow the benzoin to dry.
4. Apply the urine bag.
   - For boys: Ensure that the penis is fully inside the bag; a portion of the scrotum may or may not be inside the bag, depending upon scrotal size.
   - For girls: Apply the narrow portion of the bag on the perineal space between the anal and vulvar areas first for best adhesion, then spread the remaining adhesive section (Fig. 2).
5. Tuck the bag downward inside the diaper to discourage leaking.
6. Check the bag frequently for urine (Fig. 3).

Bladder Exstrophy

In classic bladder exstrophy, a midline closure defect occurs during the embryonic period of gestation, leaving the bladder open and exposed outside of the abdomen. The bony pelvis may also be malformed, resulting in an opening in the pelvic arch. Bladder exstrophy may be diagnosed by prenatal ultrasound. Complications include UTI from ascending organisms. Treatment of bladder exstrophy involves surgical repair.

Nursing Assessment

On physical examination of the infant or child, note the red appearance to the bladder seen on the abdominal wall (Fig. 42.1). Draining urine will be visible. Note excoriation of abdominal skin around the bladder resulting from contact with urine. A malformed urethra may be present in females, while males may have an unformed or malformed penis or a normal penis with an epispadias.

Nursing Management

Nursing management consists of preventing infection and skin breakdown, providing postoperative care, and catheterizing the stoma.

Preventing Infection and Skin Breakdown

Bladder exstrophy requires surgical repair. In the preoperative period, care is focused on protecting the exstrophied bladder and preventing infection. Keep the infant in a supine position; keep the bladder moist and cover it with a sterile plastic bag. Change soiled diapers immediately to prevent contamination of the bladder with feces. Sponge-bathe the infant rather than immersing him or her in water to prevent pathogens in the bath water from entering the bladder. Prevent breakdown of the surrounding abdominal skin by applying protective barrier creams. In some instances it may be necessary to consult the ostomy nurse for advice on dealing with the abdominal skin excoriation. If

(text continues on page 1392)

Nursing Care Plan 42.1

OVERVIEW FOR THE CHILD WITH A GENITOURINARY DISORDER

NURSING DIAGNOSIS: Activity intolerance related to generalized edema, anemia, or generalized weakness as evidenced by verbalization of weakness or fatigue, elevated heart rate, respiratory rate, or blood pressure with activity, complaint of shortness of breath with play or activity

Outcome Identification and Evaluation

Child will display increased activity tolerance, desire to play without developing symptoms of exertion.

Intervention: Promoting Activity

- Encourage activity or ambulation per physician's orders: *early mobilization results in better outcomes.*
- Observe child for symptoms of activity intolerance such as pallor, nausea, lightheadedness, or dizziness or changes in vital signs *to determine level of tolerance.*
- If child is on bed rest, perform range-of-motion exercises and frequent position changes, *as negative changes to the musculoskeletal system occur quickly with inactivity and immobility.*
- Cluster nursing care activities and plan for periods of rest before and after exertional activities *to decrease oxygen need and consumption.*
- Refer the child to physical therapy *for exercise prescription to increase skeletal muscle strength.*

NURSING DIAGNOSIS: Excess fluid volume related to decreased protein in the bloodstream, decreased urine output, sodium retention, possible inappropriate fluid intake, or altered hormone levels inducing fluid retention as evidenced by edema, bloating, weight gain, oliguria, azotemia, or changes in heart and lung sounds

Outcome Identification and Evaluation

Child will attain appropriate fluid balance, will lose weight (fluid), edema or bloating will decrease, lung sounds will be clear and heart sounds normal.

Intervention: Encouraging Fluid Loss

- Weigh child daily on same scale in similar amount of clothing; *in children, weight is the best indicator of changes in fluid status.*
- Monitor location and extent of edema (measure abdominal girth daily if ascites present): *decrease in edema indicates positive increase in oncotic pressure.*
- Auscultate lungs carefully to determine presence of crackles (*indicating pulmonary edema*).
- Assess work of breathing and respiratory rate (*increased work of breathing is associated with pulmonary edema*).
- Assess heart sounds for presence or absence of gallop (*presence of S3 may indicate fluid overload*).
- Maintain fluid restriction as ordered *to decrease intravascular volume and workload on the heart.*
- Strictly monitor intake and output *to quickly note discrepancies and provide intervention.*
- Provide sodium-restricted diet as ordered (*restricting sodium in the diet allows for better renal excretion of extra fluid*).
- Administer diuretics as ordered and monitor for side effects of those medications. *Diuretics encourage excretion of fluid and elimination of edema, reduce cardiac filling pressures, and increase renal blood flow. Side effects include electrolyte imbalance as well as orthostatic hypotension.*

(continued)

Nursing Care Plan 42.1 (continued)

NURSING DIAGNOSIS: Imbalanced nutrition: less than body requirements related to anorexia and protein loss as evidenced by weight, length/height, and/or BMI below average for age

Outcome Identification and Evaluation

Child will improve nutritional intake, resulting in steady increase in weight and length/height.

Intervention: Promoting Adequate Nutrition

- Determine body weight and length/height norm for age, *to determine goal to work toward.*
- Assess child for food preferences that fall within dietary restrictions, *as the child will be more likely to consume adequate amounts of foods that he or she likes.*
- Weigh daily or weekly (according to physician order or institutional standard) and measure length/height weekly *to monitor for increased growth.*
- Offer highest calorie meals at the time of day when the child's appetite is the greatest (*to increase likelihood of increased caloric intake*).
- Provide increased calorie shakes or puddings within diet restriction (*high calorie foods increase weight gain*).
- Administer vitamin and mineral supplements as prescribed *to attain/maintain vitamin and mineral balance in the body.*

NURSING DIAGNOSIS: Imbalanced nutrition: more than body requirements related to increased appetite secondary to steroid therapy as evidenced by weight greater than 95th percentile for age or recent increase in weight

Outcome Identification and Evaluation

Child will demonstrate balanced nutritional intake, will maintain current weight or steadily lose excess weight.

Intervention: Encouraging Appropriate Nutritional Intake

- Determine ideal body weight and body mass index for age *to determine goal to work toward.*
- Consult dietitian *for guidance in planning nutrient-rich diet in context of restrictions.*
- Evaluate for emotional/psychological reasons for overeating *to address these concerns.*
- Formulate a contract with the child *to involve him/her in the planning process and encourage compliance with the plan.*
- With the child, plan for daily exercise/activity *to expend excess calories.*
- Instruct the child/parent about appropriate nutrient-rich foods to choose within the constraints of diet and fluid restrictions *to provide basis for ongoing diet management at home.*
- Weigh child twice weekly on same scale *to determine progress toward goal.*

NURSING DIAGNOSIS: Impaired urinary elimination related to urinary tract infection or other urologic condition, or other factors such as ignoring urge to void at appropriate time as evidenced by urinary retention or incontinence, dribbling, urgency, or dysuria

Outcome Identification and Evaluation

Child will maintain continence; will void in the toilet.

Intervention: Promoting Adequate Urinary Elimination

- Assess the child's usual voiding pattern and success within that pattern *to determine baseline.*
- Develop a schedule for bladder emptying *to encourage voiding in the toilet.*
- Maintain adequate hydration, *as dehydration irritates the bladder.*
- Avoid constipation, *as constipation is associated with inability to adequately empty bladder.*
- Teach parents to restrict child's fluid intake after dinner *to avoid bedwetting.*
- Ensure child voids prior to going to bed *to avoid bedwetting.*
- Teach bladder-stretching exercises as prescribed per physician *to increase bladder capacity.*

Nursing Care Plan 42.1 (continued)

NURSING DIAGNOSIS: Urinary retention related to anatomic obstruction, sensory motor impairment or dysfunctional voiding as evidenced by dribbling, inadequate bladder emptying

Outcome Identification and Evaluation

Child's bladder will empty adequately, according to pre-established quantities and frequencies individualized for the child (usual urine output is 0.5 to 2 mL/kg/hour).

Intervention: Promoting Successful Bladder Emptying

- Assess child's ability to adequately empty bladder via history focused on character and duration of lower urinary symptoms *to establish baseline.*
- Assess for history of fecal impaction or encopresis, *as alterations in bowel elimination may have a negative impact on urinary elimination.*
- Assess for bladder distention by palpation or urinary retention by post-void residual obtained via catheterization or bladder ultrasound *to determine extent of retention.*
- Maintain adequate hydration *to avoid irritating effects of dehydration on the bladder.*
- Schedule voiding *to decrease bladder overdistention.*
- In the child with significant urinary retention, teach parents/child the technique of clean intermittent catheterization, *which allows for regular complete bladder emptying.*

NURSING DIAGNOSIS: Disturbed body image related to anatomic differences, short stature, or effects of long-term corticosteroid use as evidenced by verbalization of dissatisfaction with the child's or adolescent's looks

Outcome Identification and Evaluation

Child or adolescent will display appropriate body image, will look at self in mirror and participate in social activities.

Intervention: Promoting Body Image

- Acknowledge feelings of anger over body changes and illness: *venting feelings is associated with less body image disturbance.*
- Support the child's or teen's choices of comfortable, fashionable clothing *that may disguise anatomic abnormalities and dialysis tubing.*
- Involve the child and especially the teen in the decision-making process, *as a sense of control of their own body will improve body image.*
- Encourage children or teens to spend time with others their own age who have short stature or other effects of renal disorders: *a peer's opinions are often better accepted than those of persons in authority, such as parents or health care professionals.*

NURSING DIAGNOSIS: Knowledge deficit related to lack of information regarding complex medical condition, prognosis, and medical needs as evidenced by verbalization, questions, or actions demonstrating lack of understanding regarding child's condition or care

Outcome Identification and Evaluation

Child and parents will verbalize accurate information and understanding about condition, prognosis, and medical needs: *Child and parents demonstrate knowledge of condition and medications and will demonstrate therapeutic procedures the child requires.*

Intervention: Educating the Child and Parents

- Assess child's and parents' willingness to learn: *Child and parents must be open to learning for teaching to be effective.*
- Provide parents with time to adjust to diagnosis: *will facilitate adjustment and ability to learn and participate in child's care.*
- Teach in short sessions: *many short sessions are found to be more helpful than one long session.*
- Repeat information: *allows parents and child time to learn and understand.*
- Individualize teaching to the parents' and child's level of understanding (depends on age of child, physical condition, memory) *to ensure understanding.*
- Provide reinforcement and rewards *to facilitate the teaching/learning process.*
- Use multiple modes of learning involving many senses (written, verbal, demonstration, and videos) when possible: *child and parents are more likely to retain information when presented in different ways using many senses.*

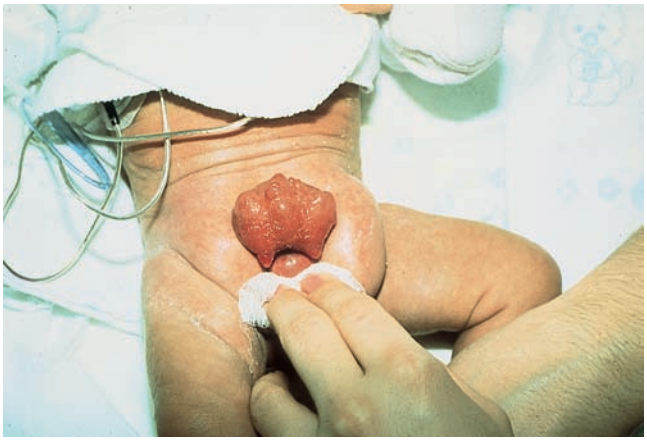

FIGURE 42.1 Note the bright-red color of the bladder exstrophy.

an orthopedic surgeon is involved due to the malformed pubic arch, follow through with recommended positioning or bracing to prevent further separation of the pubic arch.

Providing Postoperative Care

Nursing management in the postoperative period focuses on preventing infection. Keep the infant supine and quickly change soiled diapers to prevent contamination of the incision with stool. Surgical reconstruction of the bladder within the pelvic cavity and reconstruction of a urethra are done if enough bladder tissue is present. An indwelling urethral catheter or suprapubic tube will allow urinary drainage, allowing the bladder to rest in the initial postoperative period. Ensure that catheters drain freely and do not become kinked. Sometimes tubes or catheters used in the postoperative period require irrigation. Refer to the institution's policy and the surgeon's orders for specifics related to urinary catheter irrigation.

Manage bladder spasms with oxybutynin (Ditropan) or belladonna and opioid (B & O) suppositories as ordered. Note blood-tinged urine upon return from surgery, with clearing of urine within hours to days.

Catheterizing the Stoma

If bladder tissue is insufficient for repair, then the bladder is removed and a continent urinary reservoir created. The ureters are connected to a portion of the small intestine that is separated from the gastrointestinal (GI) tract, thus creating a urinary reservoir. The intestines are reanastomosed to leave the GI tract intact and separate from the GU tract. A stoma is created on the abdominal wall; it provides access to the urinary reservoir (Fig. 42.2). The stoma is catheterized about four times per day to empty the reservoir of urine. Urine from an intestine-based urinary reservoir tends to be mucus-like and is often cloudier than urine from a urinary bladder. Teach parents the procedure for catheterizing the urinary reservoir and instruct them to call the child's urologist or pediatrician if signs or symptoms of UTI occur.

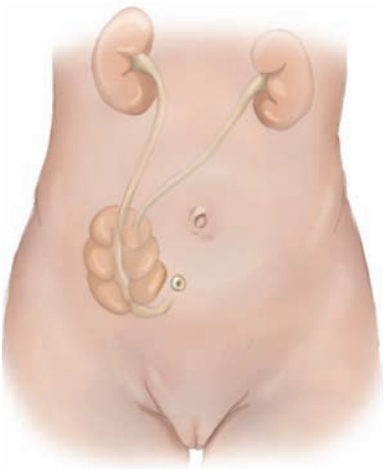

FIGURE 42.2 The abdominal stoma allows for urinary continence and requires catheterization.

▶ *Take* NOTE!

About one third of all children with urologic malformations are at high risk for the development of latex allergy. Latex allergy can result in anaphylaxis. Primary prevention of latex allergy is warranted in all children with urologic malformations, so use latex-free gloves, tubes, and catheters in these children.

Hypospadias/Epispadias

Hypospadias is a urethral defect in which the opening is on the ventral surface of the penis rather than at the end of the penis (Fig. 42.3). Epispadias is a urethral defect in which the opening is on the dorsal surface of the penis. In either case, the opening may be near the glans of the

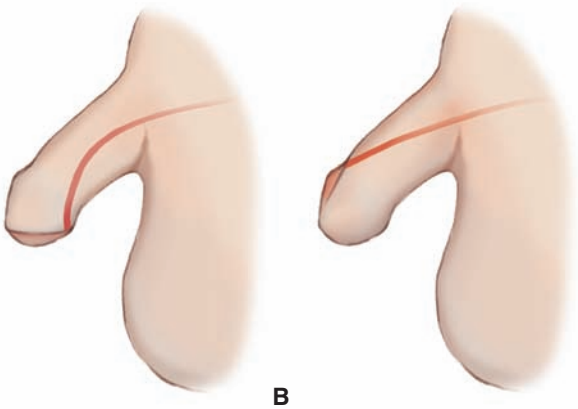

FIGURE 42.3 (**A**) Hypospadias: the urethral opening is located on the ventral side of the penis. (**B**) Epispadias: the urethral opening is located on the dorsal side of the penis.

penis, midway along the penis, or near the base. If left uncorrected, the boy may not be capable of appropriately aiming a urinary stream from a standing position. The abnormal placement of the urethral opening may interfere with the deposition of sperm during intercourse, leaving the man infertile. Also, if left uncorrected, the boy's self-esteem and body image may be damaged by the abnormal appearance of his genitalia. For these reasons, the defect is usually repaired sometime after about 1 year of age. The goal of surgical correction for either condition is to provide for an appropriately placed meatus that allows for normal voiding and ejaculation. The meatus is moved to the glans penis and the urethra is reconstructed as needed. Most repairs are accomplished in one surgery. More extensive reconstructions may require two stages.

Nursing Assessment

Note history of an unusual urine stream. Inspect the penis for placement of the urethral meatus: it may be slightly off center of the glans or may be present somewhere along the shaft of the penis. Inspect for chordee, a fibrous band causing the penis to curve downward. Palpate for presence or absence of testicles in the scrotal sac, because cryptorchidism (undescended testicles) often occurs with hypospadias, as do hydrocele and inguinal hernia.

Nursing Management

The newborn with hypospadias or epispadias should not undergo circumcision until after surgical repair of the urethral meatus. In more extreme cases, the surgeon may need to use some of the excess foreskin while reconstructing the meatus. Nursing management of the infant who has undergone a hypospadias or epispadias repair focuses on providing routine postoperative care and parent education.

Providing Postoperative Care

Postoperatively, assess urinary drainage from the urethral stent or drainage tube, which allows for discharge of urine without stress along the surgical site. Ensure that the urinary drainage tube remains carefully taped with the penis in an upright position to prevent stress on the urethral incision. The penile dressing is usually a compression type, used to decrease edema and bruising. Administer antibiotics if prescribed. Assess for pain, which is usually not extensive, and administer analgesics or antispasmodics (oral oxybutynin or B & O suppository) as needed for bladder spasms.

▶ *Take* NOTE!

Bladder spasms may also be managed effectively through the use of epidural analgesia, which is being used more frequently in the postoperative period in the pediatric population.

Double diapering is a method used to protect the urethra and stent or catheter after surgery; it also helps keep the area clean and free from infection. The inner diaper contains stool and the outer diaper contains urine, allowing separation between the bowel and bladder output. Nursing Procedure 42.2 details the double-diapering technique. Change the outside (larger) diaper when the child is wet; change both diapers when the child has a bowel movement.

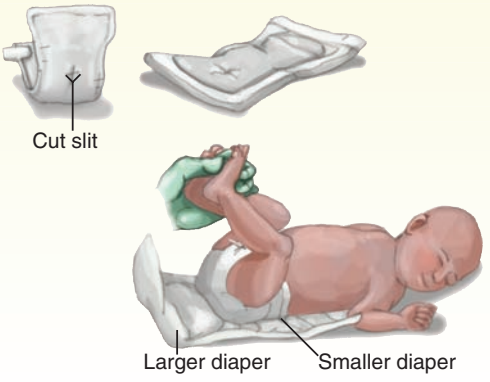
Educating the Family

If the child is to be discharged with the urinary catheter in place (which is common), teach the parents how to care for

Nursing Procedure 42.2

DOUBLE DIAPERING

1. Cut a hole or a cross-shaped slit in the front of the smaller diaper.
2. Unfold both diapers and place the smaller diaper (with the hole) inside the larger one.
3. Place both diapers under the child.
4. Carefully bring the penis (if applicable) and catheter/stent through the hole in the smaller diaper and close the diaper.
5. Close the larger diaper, making sure the tip of the catheter/stent is inside the larger diaper.



Pictures and text adapted from Children's Healthcare of Atlanta (2004). *Double diapering.*

the catheter and drainage system. Have parents demonstrate their ability to irrigate the catheter should a mucus plug occur. Tub baths are generally prohibited until it is time to remove the penile dressing. Roughhousing, ride-on toys, or any activity involving straddling is not allowed for 2 to 3 weeks.

Obstructive Uropathy

Obstructive uropathy is an obstruction at any level along the upper or lower urinary tract. This discussion will focus on congenital structural defects, though obstruction can also occur as a result of other disease processes (acquired obstructive uropathy). The most common sites of obstruction are listed in Table 42.1. The defect may be unilateral or bilateral and can cause partial or complete obstruction of urine flow, resulting in dilation of the affected kidney (hydronephrosis). Complications include recurrent UTI, renal insufficiency, and progressive damage to the kidney resulting in renal failure.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1381. Assessment findings pertinent to obstructive uropathy are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Recurrent UTI
- Incontinence
- Fever
- Foul-smelling urine
- Flank pain
- Abdominal pain
- **Urinary frequency**
- Urinary **urgency**
- Dysuria
- **Hematuria**

Explore the child's current and past medical history for risk factors such as:

- "Prune belly" syndrome
- Chromosome abnormalities
- Anorectal malformations
- Ear defects

Physical Examination and Laboratory and Diagnostic Tests

Palpate the abdomen for presence of an abdominal mass (hydronephrotic kidney). Assess the blood pressure; elevation may occur if renal insufficiency is present. Many cases of obstructive uropathy may be diagnosed with prenatal ultrasound if the obstruction has been significant enough to cause hydronephrosis or dilatation elsewhere along the urinary tract.

Nursing Management

Surgical correction is specific to the type of obstruction and generally consists of removal of the obstruction, reimplantation of the ureters as necessary, and occasionally creation of a urinary diversion. Postoperatively, assess urine output via vesicostomy, nephrostomy, suprapubic tube, or urethral catheter for color, clots, clarity, and amount. Encourage fluids once the child can tolerate them orally. Administer analgesics and/or antispasmodics as needed for bladder spasms. Teach parents care of vesicostomy or drainage tubes, with which the child may be discharged.

▶ *Take* NOTE!

Upon return from surgery, most children have intravenous fluids without added potassium infusion. Potassium is withheld from the intravenous fluid until adequate urine output is established post-operatively to avoid the development of hyperkalemia should the kidneys fail to function properly.

Hydronephrosis

Hydronephrosis is a condition in which the pelvis and calyces of the kidney are dilated (Fig. 42.4). Hydronephrosis may occur as a congenital defect, as a result of obstructive uropathy, or secondary to vesicoureteral reflux. Congenital hydronephrosis may be revealed on prenatal ultrasound. Complications of hydronephrosis include renal insufficiency, hypertension, and eventually renal failure.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1381. Assessment findings pertinent to hydronephrosis are discussed below.

Health History

Elicit a description of the present illness and chief complaint. The infant may be asymptomatic, but signs and symptoms reported during the health history might include:

- Failure to thrive
- Intermittent hematuria
- Presence of an abdominal mass
- Signs and symptoms associated with a UTI such as fever, vomiting, poor feeding, and irritability

Explore the child's current and past medical history for risk factors such as:

- Maternal oligohydramnios or polyhydramnios (congenital hydronephrosis)
- Elevated levels of serum alpha-fetoprotein (congenital hydronephrosis)

TABLE 42.1 Common Sites of Obstructive Uropathy

Disorder	Site	Illustration
Ureteropelvic junction (UPJ) obstruction	Junction of the upper ureter with the pelvis of the kidney	Urinary tract with unilateral hydronephrosis and narrowing of the UPJ on that side Ureterovesical junction (UVJ) obstruction	Junction of the lower ureter and the bladder	Urinary tract with unilateral hydronephrosis and dilated ureters with narrowing of the UVJ on that side Ureterocele	Ureter swells into the bladder	Bladder with cystic pouch where ureters insert (unilateral) Posterior urethral valves (males only)	Flaps of tissue in the proximal urethra	Distended proximal urethra, bladder, ureters, and hydronephrosis 

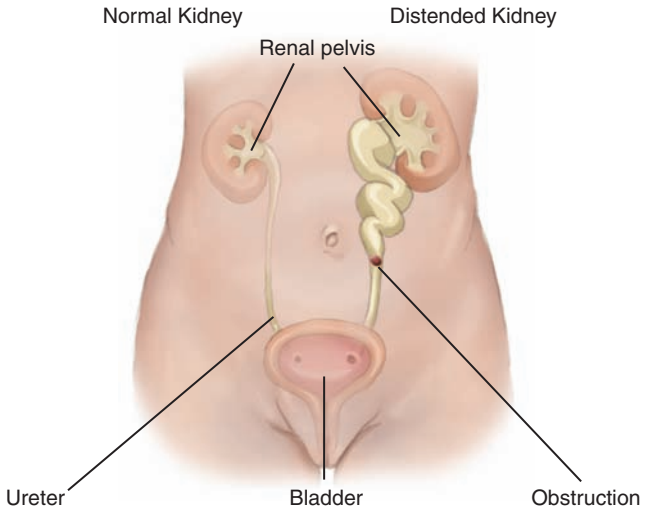

FIGURE 42.4 Hydronephrosis.

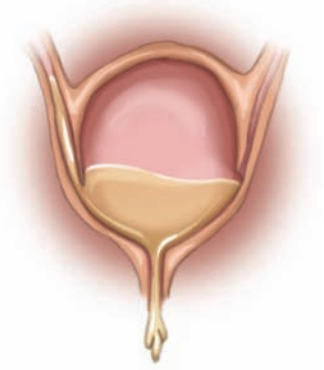

FIGURE 42.5 Note retrograde flow of urine up the ureter upon bladder contraction.

Physical Examination and Diagnostic and Laboratory Tests

Monitor the blood pressure of infants and children suspected of having hydronephrosis. Palpation of the abdomen may reveal enlarged kidney(s) or a distended bladder. A voiding cystourethrogram (VCUG) will be performed to determine the presence of a structural defect that may be causing the hydronephrosis. Other diagnostic tests, such as a renal ultrasound or an intravenous pyelogram, may also be performed to clarify the diagnosis.

Nursing Management

Teach the parents signs and symptoms of UTI and sepsis, as these complications may occur. The parents should observe the child for adequacy of urine output and hydration status. Teach the parents to perform appropriate perineal hygiene and to avoid using irritants in the genital area. The infant or child with hydronephrosis will need follow-up with a pediatric nephrologist or urologist.

Vesicoureteral Reflux

Vesicoureteral reflux (VUR) is a condition in which urine from the bladder flows back up the ureters. This reflux of urine occurs during bladder contraction with voiding (Fig. 42.5). Reflux may occur in one or both ureters. If reflux occurs when the urine is infected, the kidney is exposed to bacteria and pyelonephritis may result. The increased pressure placed upon the kidney with reflux can cause renal scarring and lead to hypertension later in life and, if severe, renal insufficiency or failure.

Primary VUR results from a congenital abnormality at the vesicoureteral junction that results in incompetence of the valve. Secondary VUR is related to other structural or functional problems such as neurogenic bladder, bladder dysfunction, or bladder outlet obstruction. As many as 30% to 40% of all children diagnosed with UTI have primary VUR (Thompson et al., 2005).

VUR is graded according to its severity: grade 1 results in minor dilatation of the proximal ureter and grade V is severe dilatation of the ureter and pelvis of the kidney (Wald, 2006). Grade I and II VUR cases usually resolve spontaneously, but grade III to V cases are generally associated with recurrent UTIs, hydronephrosis, and progressive renal damage.

The goal of therapeutic management of VUR is prevention of pyelonephritis and subsequent renal scarring, which may contribute to the development of hypertension later in life (Ellsworth et al., 2000). Management includes antibiotic prophylaxis and hygiene/voiding practices to prevent UTI. Serial urine cultures are used to determine recurrence of UTI. Biannual, annual, or biennial radionuclide VCUGs are performed to determine the status of VUR.

Grade III, IV, and V cases usually warrant surgical intervention. The ureters are resected from the bladder and reimplanted elsewhere in the bladder wall to regain functionality.

▶ *Take* NOTE!

The keys to prevention of long-term sequelae such as hypertension in children with urologic conditions are early diagnosis and intervention, prevention of infection, and close clinical follow-up. Nurses play a key role in monitoring and education.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1381. Assessment findings pertinent to VUR are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Fever
- Dysuria
- Frequency or urgency
- Nocturia
- Hematuria
- Pain in the back, abdomen, or flank

Explore the child's current and past medical history for risk factors such as:

- Recurrent UTI in the female
- Single episode of UTI in the male
- Congenital defect
- Family history of VUR

For the child who is receiving ongoing follow-up for VUR, determine whether UTIs have occurred since the last visit, as well as the name and dose of prophylactic antibiotic.

Physical Examination

Monitor the blood pressure for elevation. Palpate the abdomen for presence of a mass (if hydronephrosis is present). VCUG may be used to diagnose VUR.

Nursing Management

Nursing management for the child with VUR includes preventing infection and providing postoperative care.

Preventing Infection

When VUR is present, the goal is to avoid urine infection so that infected urine cannot gain access to the kidneys. Initially, most cases of VUR are managed medically. Teach the child to empty the bladder completely. Teach child and parents appropriate perineal hygiene as well as toileting hygiene to prevent recurrence of UTI. Teach parents about the antibiotic therapy prescribed: the child will be maintained on a low daily dose to prevent UTI. The drug is most effective when given at bedtime because of urinary stasis overnight. Inform parents of the schedule for serial urine cultures and follow-up VCUG.

Providing Postoperative Care

If VUR is severe or if UTI is recurrent, surgical correction will be necessary. In the first 24 to 48 hours after surgery, maintain the intravenous fluid rate at 1.5 times maintenance to encourage a high urinary output. Monitor urine output via the Foley catheter; urine should be bloody initially, clearing within 2 to 3 days. If ureteral stents are present, monitor urine output from those as well. Administer analgesics for incisional pain relief and antispasmodics or B & O suppositories as needed for bladder spasms. Encourage ambulation and advancement of diet as ordered to promote return of appropriate bowel function. Teach parents that prophylactic antibiotics will be given until 1 to 2 months after surgery, when the VCUG demonstrates absence of reflux.

▶ *Take* NOTE!

When caring for the child who has undergone urologic surgery, avoid manipulating the Foley or suprapubic catheter: catheter manipulation contributes to bladder spasms.

URINARY TRACT INFECTION

UTI occurs most often as a result of bacteria ascending to the bladder via the urethra. UTI is the most common serious bacterial infection in children (Dulczak & Kirk, 2005), with lower tract infection (cystitis) being less serious than upper tract infection (pyelonephritis). As many as 7% of females and 2% of males will experience a UTI by age 6 years (Alper & Curry, 2005). UTI is most common in infants and young children. It occurs more frequently in males than females during infancy, but after 1 year of age is more common in females. One explanation for the more common occurrence in females is that the female's shorter urethra allows bacteria to have easier access to the bladder. The urethra is also located quite close to the vagina and anus in females, allowing spread of bacteria from those areas. The sexually active female adolescent is at risk for the development of cystitis, as bacteria may be forced in to the urethra by pressure from intercourse. The male may be somewhat protected from UTI by the antibacterial properties of prostate secretions.

UTI presents differently in infants than it does in children. Infants may exhibit fever, irritability, vomiting, failure to thrive, or jaundice. Children may also experience fever and vomiting and may have dysuria, frequency, hesitancy, urgency, or pain.

Pathophysiology

E. coli accounts for about 60% to 80% of all UTIs, as it is usually found in the perineal and anal region, close to the urethral opening (Alper & Curry, 2005). Other organisms include *Klebsiella, Staphylococcus aureus, Proteus, Pseudomonas,* and *Haemophilus.* Numerous factors may contribute to bacterial proliferation. Urinary stasis contributes to the development of a UTI once the bacteria have gained entry. Urine that remains in the bladder after voiding allows bacteria to grow rapidly. A decreased fluid intake also contributes to bacterial growth, as the bacteria become more concentrated. If the urine is alka-

line, bacteria are better able to flourish. Untreated bladder infection may allow reflux of infected urine up the ureters to the kidneys and result in pyelonephritis, a more serious infection.

Therapeutic Management

UTIs are treated with either oral or intravenous antibiotics, depending on the severity of the infection. Urine culture and sensitivity determines the appropriate antibiotic. A 7- to 14-day course of antibiotics is often prescribed, though 2- to 5-day courses may be as effective (Alper & Curry, 2005). Adequate fluid intake is necessary to flush the bacteria from the bladder. Fever management may also be needed.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1381. Assessment findings pertinent to UTI are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Fever
- Nausea or vomiting
- Chills
- Abdomen, back, or flank pain
- Lethargy
- Jaundice (in the neonate)
- Poor feeding or "just not acting right" (in the infant)
- Urinary urgency or frequency
- Burning or stinging with urination (the infant may cry with urination, the toddler may grab the diaper)
- Foul-smelling urine
- Poor appetite (child)
- Enuresis or incontinence in a previously toilet-trained child
- Blood in the urine

Explore the child's current and past medical history for risk factors such as:

- Previous UTI
- Obstructive uropathy
- Inadequate toileting hygiene (often occurs with preschool girls)
- VUR
- Constipation
- Urine holding or dysfunctional voiding
- Neurogenic bladder
- Uncircumcised male
- Sexual intercourse
- Pregnancy
- Chronic illness

Physical Examination

In the neonate or young infant, observe for jaundice or increased respiratory rate. In infants and children, inspect the perineal area for redness or irritation. Observe the urine for visible blood, cloudiness, dark color, sediment, mucus, or foul odor. Note pallor, edema, or elevated blood pressure. Palpate the abdomen. Note distended bladder, abdominal mass, or tenderness, particularly in the flank area.

Laboratory and Diagnostic Tests

Common laboratory and diagnostic studies ordered for the assessment of UTI include:

- Urinalysis (clean-catch, suprapubic, or catheterized): may be positive for blood, nitrites, leukocyte esterase, white blood cells, or bacteria (bacteriuria)
- Urine culture: will be positive for infecting organism
- Renal ultrasound: may show hydronephrosis if child also has a structural defect
- VCUG: not usually performed until the child has been treated with antibiotics for at least 48 hours, as infected urine tends to reflux up the ureters anyway. VCUG performed once the urine has regained sterility may be positive for VUR.

Renal ultrasound, VCUG, and other nuclear medicine scans such as the DMSA scan may be indicated in certain populations. The physician or nurse practitioner will determine the need for radiologic testing.

Nursing Management

Goals for nursing management include eradicating infection, promoting comfort, preventing complications, and preventing recurrence of infection.

Eradicating Infection

The child who can tolerate oral intake will be prescribed an oral antibiotic. The child who has protracted vomiting related to the UTI or who has suspected pyelonephritis will require hospitalization and intravenous antibiotics. Any infant less than 3 months of age with fever and suspected UTI should also be hospitalized for administration of intravenous antibiotics. Administer oral or intravenous antibiotics as prescribed. Urge the parent to complete the entire course of oral antibiotic at home, even though the child is feeling better. Administer intravenous fluids as ordered or encourage generous oral fluid intake to help flush the bacteria from the bladder.

Promoting Comfort

Administer antipyretics such as acetaminophen or ibuprofen to reduce fever. A heating pad or warm compress may help relieve abdomen or flank pain. If the child is afraid to urinate due to burning or stinging, encourage voiding in a warm sitz or tub bath.

EVIDENCE-BASED PRACTICE 42.1
Antibiotics and Urinary Tract Infections in Children

● Study
Urinary tract infections (UTI) commonly occur in children, causing frequent and painful urination. Traditionally, 7- to 10-day courses have been recommend for treating UTI in children. In the search for options to decrease side effects and improve costs, short courses of antibiotics may provide the solution. The authors included 10 randomized and quasi-randomized trials with a total of 652 participants. Participants included were low-risk, between the ages of 3 months and 18 years with culture-proven UTI. The studies assessed the benefits and harms of short-course (2–4 days) antibiotic treatment compared with that of standard duration (7–14 days).

▲ Findings
The authors found that a 2- to 4-day course of oral antibiotics appears to be as effective as the traditional long course (7–14 days) in eradicating UTI in children. Additionally, there was no statistical significance demonstrated in terms of repeat UTI within 1 to 15 months after the original infection.

■ Nursing Implications
Shorter courses of antibiotic treatment are much easier for families to comply with and complete, yet families may be accustomed to longer courses of antibiotic treatment and need further education. Educate families that the shorter course is indeed effective in treating UTI. Nurses should advocate for short-course antibiotic treatment in low-risk children with UTI.

Michael, M., Hodson, E. M., Craig, J. C., Martin, S., & Voyer, V. A. (2007). Short versus standard duration oral antibiotic therapy for acute urinary tract infection in children. *The Cochrane Library 2007, 4*. Indianapolis: John Wiley & Sons.

Preventing Recurrence of Infection
Encourage the parents to return as ordered for a repeat urine culture after completion of the antibiotic course to ensure eradication of bacteria. Teaching Guidelines 42.1 gives further information on preventing UTI.

TEACHING GUIDELINES 42.1
Preventing Urinary Tract Infection in Females

- Drink enough fluid (to keep urine flushed through bladder).
- Drink cranberry juice to acidify the urine. Avoid colas and caffeine, which irritate the bladder.
- Urinate frequently and do not "hold" urine (to discourage urinary stasis).
- Avoid bubble baths (they contribute to vulvar and perineal irritation).
- Wipe from front to back after voiding (to avoid contaminating the urethra with rectal material).
- Wear cotton underwear (to decrease the incidence of perineal irritation).
- Avoid wearing tight jeans or pants.
- Wash the perineal area daily with soap and water.
- While menstruating, change sanitary pads frequently to discourage bacterial growth.
- Void immediately after sexual intercourse.

ENURESIS

Enuresis is continued incontinence of urine past the age of toilet training. Box 42.1 gives further definitions related to enuresis. Nocturnal enuresis generally subsides by 6 years of age; if it does not, further investigation and treatment may be warranted. Occasional daytime wetting or dribbling of urine is usually not a cause for concern, but frequent daytime wetting concerns both the child and the parents. Nocturnal enuresis may persist in some children into late childhood and adolescence, causing significant distress for the affected child and family.

In some children, enuresis may occur secondary to a physical disorder such as diabetes mellitus or insipidus, sickle cell anemia, ectopic ureter, or urethral

BOX 42.1 Definitions Related to Enuresis

- **Primary enuresis:** enuresis in the child who has never achieved voluntary bladder control
- **Secondary enuresis:** urinary incontinence in the child who previously demonstrated bladder control over a period of at least 3 to 6 consecutive months
- **Diurnal enuresis:** daytime loss of urinary control
- **Nocturnal enuresis:** nighttime bedwetting

obstruction. Other causes common to both diurnal and nocturnal enuresis include a urine-concentrating defect, UTI, constipation, and emotional distress (sometimes serious). The most frequent cause of daytime enuresis is dysfunctional voiding or holding of urine, though giggle incontinence and stress incontinence also occur. Nocturnal enuresis may be related to a high fluid intake in the evening, obstructive sleep apnea, sexual abuse, a family history of enuresis, or inappropriate family expectations. Physical causes of enuresis must be treated; further management of the disorder focuses on behavioral training, which may be augmented with the use of enuresis alarms or medications.

Nursing Assessment

Elicit a description of the present illness and chief complaint. Determine the age of toilet training and when or if the child achieved successful daytime and nighttime dryness. Inquire about urine-holding behaviors such as squatting, dancing, or staring as well as rushing to the bathroom (diurnal enuresis). Inquire about the amount and types of fluid the child typically consumes before bedtime (nocturnal enuresis). Assess for risk factors such as:

- Family disruption or other stressors
- Chronic constipation (carefully assess bowel movement patterns)
- Excessive family demands related to toileting patterns
- History of being difficult to arouse from sleep
- Family history of enuresis

Assess the child's cognitive status: developmentally delayed children may take significantly longer to achieve urine continence than their typical same-age peers. Assess for short stature or elevated blood pressure, as these may occur when renal abnormalities are present.

Nursing Management

For the child with diurnal enuresis, encourage him or her to increase the amount of fluid consumed during the day in order to increase the frequency of the urge to void. Set a fixed schedule for the child to attempt to void throughout the day. These practices will usually be sufficient to retrain the child's voiding patterns. The child with nocturnal enuresis without a physiologic cause for bedwetting may present a management challenge.

Educating the Child and Family About Nocturnal Enuresis

Teach the family that the child is not lazy, nor does he or she wet the bed intentionally. Encourage the child and family to read books such as *Dry All Night: The Picture Book Technique That Stops Bedwetting* by Alison Mack or *Waking Up Dry: A Guide to Help Children Overcome Bedwetting* by Dr. Howard Bennett. Encourage the parents to limit intake of bladder irritants such as chocolate and caffeine. Teach parents to limit fluid intake after dinner and ensure that the child voids just before going to bed. Waking the child to void at 11 p.m. may also be helpful. Teach the parents to use bed pads and to make the bed with two sets of sheets and pads to decrease the workload in the middle of the night. When sleeping at home, the child should wear his or her usual underwear or pajamas. If away on a family vacation, pull-ups may decrease the stress on both the child and the parents.

Providing Support and Encouragement

It is important for the child to understand that he or she is not alone. Depending on the child's developmental level, explain that as many as 5 million people have enuresis (this can be done in terms the child can relate to, such as a proportion within a school or 100 times the number of children in one school, etc.). It is not only "little kids" who wet the bed, and all kids who wet the bed need help overcoming this problem. Parents should include the child in plans for nighttime urinary control; this helps to increase the child's motivation to become dry. Parents should set up a reward system for dry nights. Parents should include the child in bed linen changes when he or she does wet the bed, but should do so in a matter-of-fact manner rather than in a punitive way; in fact, punishment for bedwetting should always be avoided.

With patience, consistency, and time, dryness will be achieved. Provide ongoing emotional support and positive reinforcement to the child and family.

Decreasing Nighttime Voiding

Teach the family using an enuresis alarm system how to use the alarm as well as the previously mentioned techniques (Fig. 42.6 and Box 42.2). Most of these devices work by sounding an alarm when the first few drops of urine appear; the child then awakens and stops the urine flow. Over time the child becomes conditioned to either awaken when the bladder is full or stop the urine flow when sleeping.

When behavioral and motivational therapies are unsuccessful, particularly in the older child, medications may be prescribed. Teach the child and parents about the use of medications such as oxybutynin, imipramine, and desmopressin (DDAVP) if these are prescribed (refer to Drug Guide 22.1).

▶ *Take* NOTE!

Enuresis is a source of shame and embarrassment for children and adolescents. It affects the child's life emotionally, behaviorally, and socially. The family's life is also significantly affected. Treatment failures for enuresis have been correlated with adolescent low self-esteem.

FIGURE 42.6 Some children and families find great success with the use of an enuresis alarm. The alarm wakes the child at the first sign of wetness. Over time, the child learns to awaken at night in response to the sensation of a full bladder.

▸ *Consider* THIS!

Antonio Cruise, a 7-year-old boy, is brought to the clinic by his mother for his annual examination. During your assessment the mother brings up concerns that Antonio continues to wet the bed at night. She states, "I was hoping this would end on its own, but now I'm concerned that there is a problem."

What further assessment information would you obtain?

What education and interventions may be necessary for this child and family?

What can you do to provide support and encouragement for Antonio and his family?

ACQUIRED DISORDERS RESULTING IN ALTERED RENAL FUNCTION

A number of acquired disorders are responsible for alterations in renal function. They may occur as an autoimmune response or in relation to a bacterial infection. Renal dysfunction may also occur as a result of obstructive disorders or repeated VUR, as discussed earlier. Left untreated, these disorders may lead to renal failure; even when treated appropriately, sometimes the appropriate response is not achieved and acute or chronic renal failure develops. Renal disorders are the most frequent cause of hypertension in children.

BOX 42.2 Sources for Enuresis Alarms

- www.bedwettingstore.com (800) 214-9605
- www.dri-sleeper.com (877) 331-2768
- www.nytone.com (801) 973-4090
- www.pottypager.com (800) 497-6573

▸ *Take* NOTE!

Severe hypertension (blood pressure higher than the 99th percentile for age and sex) may lead to damage of the eye or vital organs (kidney, brain, or heart), or even death. Pediatric nurses must be adept at accurately measuring blood pressure in children.

Nephrotic Syndrome

Nephrotic syndrome occurs as a result of increased glomerular basement membrane permeability, which allows abnormal loss of protein in the urine. Nephrotic syndrome generally occurs in three forms: congenital, idiopathic, and secondary. Congenital nephrotic syndrome is an inherited disorder; it is rare and occurs primarily in families of Finnish descent. The prognosis is poor, though some success has occurred with early, aggressive treatment and with the advances in kidney transplantation in infants. Nephrotic syndrome may occur secondary to another condition such as systemic lupus erythematosus, Henoch-Schonlein purpura, or diabetes. Idiopathic nephrotic syndrome is the most commonly occurring type in children and is often termed minimal change nephrotic syndrome (MCNS). MCNS occurs more frequently in males than females and is most common in children less than 3 years of age. This discussion will focus primarily on MCNS. Complications of nephrotic syndrome include anemia, infection, poor growth, peritonitis, thrombosis, and renal failure.

Pathophysiology

Increased glomerular permeability results in the passage of larger plasma proteins through the glomerular basement membrane. This results in excess loss of protein (albumin) in the urine (**proteinuria**) and decreased protein and albumin (hypoalbuminemia) in the bloodstream. Protein loss in nephrotic syndrome tends to be almost exclusively albumin. Hypoalbuminemia results in a change in osmotic pressure, and fluid shifts from the bloodstream into the interstitial tissue (causing edema). This decrease in blood volume triggers the kidneys to respond by conserving sodium and water, leading to further edema. The liver senses the protein loss and increases production of lipoproteins. **Hyperlipidemia** then develops as the excess lipids cannot be excreted in the urine. Hyperlipidemia associated

with nephrotic syndrome may be quite severe, yet cholesterol levels may decrease when the nephrotic syndrome is in remission, only to rise significantly again with a relapse.

Children with nephrotic syndrome are at increased risk for clotting (thromboembolism) because of the decreased intravascular volume. They are also at increased risk for the development of serious infection, most commonly pneumococcal pneumonia, sepsis, or spontaneous peritonitis. Steroid-resistant nephrotic syndrome may result in acute renal failure.

Therapeutic Management

Medical management of MCNS usually involves the use of corticosteroids. Intravenous albumin may be used in the severely edematous child. Diuretics are also required in the edematous phase. Long-term therapy is usually required to induce remission. The nephrologist will determine the length of therapy based on the child's response. Children who have steroid-responsive MCNS generally have a favorable prognosis. Some children with MCNS exhibit a minimal response to steroid therapy or experience remissions and the MCNS is steroid-resistant. Immunosuppressive therapy such as cyclophosphamide, cyclosporine A, or mycophenolate mofetil may be necessary.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1381. Assessment findings pertinent to MCNS are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Nausea or vomiting (may be related to ascites)
- Recent weight gain
- History of periorbital edema upon waking, progressing to generalized edema throughout the day
- Weakness or fatigue
- Irritability or fussiness

Explore the child's current and past medical history for risk factors such as:

- Intrauterine growth retardation
- Young age (less than 3 years)
- Male sex

Physical Examination

The physical assessment of the child with nephrotic syndrome includes inspection and observation, auscultation, and palpation.

Observe the child for edema (periorbital, generalized [**anasarca**], or abdominal ascites). As the disease progresses, the edema also progresses to become more generalized, eventually becoming severe. Inspect the skin for a stretched, tight appearance, pallor, or skin breakdown related to significant edema (Fig. 42.7). Document height (or length) and weight. Note increased respiratory rate or increased work of breathing related to ascites and edema.

Note the blood pressure; it may be elevated in the child with nephrotic syndrome, though it is most often either normal or decreased unless the child is progressing to renal failure. Auscultate heart and lung sounds, noting abnormalities related to fluid overload. Palpate the skin, noting tautness. Palpate the abdomen and document presence of ascites.

Laboratory and Diagnostic Tests

Urine dipstick will reveal marked proteinuria. Infrequently, mild hematuria is also present. Serum protein and albumin levels will be low (often markedly so). Serum cholesterol and triglyceride levels are elevated. With continued nephrotic syndrome, creatinine and blood urea nitrogen (BUN) may become elevated.

Nursing Management

Goals for nursing management include promoting diuresis, preventing infection, promoting adequate nutrition, and educating the parents about ongoing care at home. As with other chronic disorders, provide ongoing emotional support to the child and family.

Promoting Diuresis

Administer corticosteroids as ordered. Tapering or weaning doses are required when the time comes to stop corticosteroid therapy. Administer diuretics if ordered, usually furosemide (Lasix). Children may develop hypokalemia because of potassium loss as an adverse effect of furosemide. Those children may require potassium supplementation or a diet higher in potassium-containing foods. Monitor urine output and the amount of protein in the

FIGURE 42.7 Note marked edema associated with nephrotic syndrome.

urine (by dipstick). Weigh the child daily on the same scale either naked or wearing the same amount of clothing. Assess for resolution of edema. Measure pulse rate and blood pressure every 4 hours to detect hypovolemia resulting from excessive fluid shifts. Enforce oral fluid restrictions if ordered.

In cases of severe hypoalbuminemia, intravenous albumin may be administered. Increases in the serum albumin level cause fluid to shift from the subcutaneous spaces back into the bloodstream. A diuretic such as furosemide administered immediately after the albumin infusion allows for optimal diuresis and prevents fluid overload. Refer to Drug Guide 42.1 for the nursing implications related to use of these medications.

Preventing Infection

Monitor the child's temperature. Viral illness may trigger a relapse in children with nephrotic syndrome who have achieved remission. Administer pneumococcal vaccine as prescribed (see Chapter 30 for information on immunizations). Administer prophylactic antibiotics, if prescribed. Live vaccines should be delayed until at least 2 weeks after corticosteroid or other immunosuppressive medication therapy ceases. Teach parents that if the child is unimmunized and is exposed to chickenpox, the pediatrician or nephrologist should be notified immediately so that the child may receive varicella zoster immunoglobulin.

Encouraging Adequate Nutrition and Growth

Encourage a nutrient-rich diet within prescribed restrictions. Fluid restriction is reserved for children with massive edema. Sodium intake may be restricted in the edematous child in an effort to prevent further fluid retention. Consultation with the dietitian is often helpful in meal planning because many of the foods that children like are high in sodium. Encourage protein-rich snacks. Consult with the child and family in planning meals and snacks that the child likes and will be likely to consume. Use of nutritional supplement shakes may be helpful in some children.

Educating the Family

Teach parents how to give medications and monitor for adverse effects. Demonstrate the urine dipstick technique for detecting protein, and encourage the family to keep a chart of dipstick results. The child may return to school but should avoid contact with sick playmates. If the child is exposed to another child with an infectious illness, the parents should monitor temperature and urine dipstick results more frequently to identify a relapse in nephrotic syndrome early so that treatment can begin.

Providing Emotional Support

Nephrotic syndrome is often a chronic condition, and children who are responsive to steroid treatment may enter remission only to experience relapse. This cycle of relapse and remission takes an emotional toll on the child and family. Frequent hospitalizations require the child to miss school and the parents to miss work; this creates further stress for the family. The child may experience social isolation because he or she must avoid exposure to infections or because of self-esteem problems. The child may be dissatisfied with his or her appearance because of edema and weight gain, short stature, and the classic "moon face" associated with chronic steroid use.

Provide emotional support to the child and family. Encourage them in their efforts to maintain the treatment plan. Introduce the child to other youngsters with chronic renal conditions. Refer families to the National Kidney Foundation (www.kidney.org) for information about local support groups and resources.

Acute Glomerulonephritis

Acute glomerulonephritis is a condition is which immune processes injure the glomeruli. Immune mechanisms cause inflammation, which results in altered glomerular structure and function in both kidneys. It often occurs following an infection, usually an upper respiratory or skin infection. The most common form is acute poststreptococcal glomerulonephritis (APSGN), and the following discussion will focus on this type. APSGN is caused by an antibody–antigen reaction secondary to an infection with a nephritogenic strain of group A beta-hemolytic streptococcus. APSGN occurs more frequently in males than females and is most common in children older than 2 years of age. The most serious complication is progression to uremia and renal failure (either acute or chronic).

There is no specific medical treatment for APSGN. Treatment is aimed at maintaining fluid volume and managing hypertension. If there is evidence of a current streptococcal infection, antibiotic therapy will be necessary.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1381. Assessment findings pertinent to acute glomerulonephritis are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Fever
- Lethargy
- Headache
- Decreased urine output
- Abdominal pain
- Vomiting
- Anorexia

Assess the child's current and past medical history for risk factors such as a recent episode of pharyngitis or other streptococcal infection, age over 2 years, or male sex.

Physical Examination and Laboratory and Diagnostic Tests

Assess the child's blood pressure for elevation, which is common. Note the presence of mild edema. Observe for signs of cardiopulmonary congestion such as increased work of breathing or cough. Auscultate the lungs for crackles and the heart for gallop. The urine dipstick test will reveal proteinuria as well as hematuria. Inspect the urine for gross hematuria, which will cause the urine to appear tea-colored, cola-colored, or even a dirty green color. Serum creatinine and BUN may be normal or elevated, the serum complement level is depressed, and the erythrocyte sedimentation rate is elevated. Laboratory findings specific to streptococcus include an elevated anti-streptolysin (ASO) titer and an elevated DNAase B antigen titer.

Nursing Management

Administer antihypertensives such as labetalol or nifedipine and diuretics as ordered. Monitor blood pressure frequently. Maintain sodium and fluid restrictions as prescribed during the initial edematous phase. Weigh the child daily on the same scale wearing the same amount of clothing. Monitor increasing urine output and note improvement in the urine color. Document resolution of edema. Provide careful neurological evaluation, as hypertension may cause encephalopathy and seizures. Children with APSGN generally are fatigued and choose bed rest during the acute phase. Provide the child with age-appropriate activities and cluster care to allow rest periods.

Some children may be managed at home if edema is mild and they are not hypertensive. Teach the family to monitor urine output and color, take blood pressure measurements, and restrict the diet as prescribed. The child cared for at home should not participate in strenuous activity until proteinuria and hematuria are resolved.

If renal involvement progresses, dialysis may become necessary.

▶ *Take* NOTE!

Avoid use of nonsteroidal anti-inflammatory drugs (NSAIDs) in children with questionable renal function, as the anti-prostaglandin action of NSAIDs may cause a further decrease in the glomerular filtration rate.

Hemolytic-Uremic Syndrome

Hemolytic-uremic syndrome (HUS) is defined by three features: hemolytic anemia, thrombocytopenia, and acute renal failure. In 90% of cases of HUS, an illness featuring diarrhea precedes the onset of the syndrome. Other causes include idiopathic, inherited, drug-related, association with malignancies, transplantation, and malignant hypertension. This discussion will focus on typical HUS, the type preceded by a diarrheal illness. Watery diarrhea progresses to hemorrhagic colitis, then to the triad of HUS. The features of HUS, as well as effects on other organs, are caused primarily by microthrombi and ischemic changes within the organs. The thrombotic events in the small blood vessels of the glomerulus lead to occlusion of the glomerular capillary loops and glomerulosclerosis, resulting in renal failure.

A verotoxin-producing strain of *E. coli,* O157:H7, causes the majority of cases, though *Streptococcus pneumoniae, Shigella dysenteriae,* and other bacteria may also be the cause. It is thought that antibiotic treatment for the aforementioned bacteria may contribute to release of the verotoxin. Undercooked ground beef accounts for most cases of *E. coli* O157:H7 infection, but it is also transmitted via the feces of numerous animals as well as unpasteurized dairy and fruit products. Transmission also occurs via human feces, and cases have been linked to public swimming pools. HUS occurs most often in children age 6 months to 4 years. Complications include chronic renal failure, seizures and coma, pancreatitis, intussusception, rectal prolapse, cardiomyopathy, congestive heart failure, and acute respiratory distress syndrome.

Therapeutic management of HUS is directed toward maintaining fluid balance; correcting hypertension, acidosis, and electrolyte abnormalities; replenishing circulating red blood cells; and providing dialysis if needed.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1381. Assessment findings pertinent to HUS are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include watery diarrhea accompanied by cramping and sometimes vomiting. After several days, the diarrhea becomes bloody and eventually improves.

Explore the child's current and past medical history for risk factors such as ingestion of ground beef, visits to a water park or to a petting zoo before the onset of the diarrheal illness, or use of antidiarrheal medications or antibiotics.

Physical Examination

Observe the child for pallor, toxic appearance, edema, **oliguria**, or **anuria**. Assess for elevated blood pressure and tenderness in the abdomen. Assess the child for neurologic involvement, which may include irritability, altered level of consciousness, seizures, posturing, or coma.

Laboratory and Diagnostic Tests

Urinalysis may reveal the presence of blood, protein, pus, and/or casts. Serum laboratory abnormalities are numerous and may include:

- Elevated BUN and creatinine
- Moderate to severe anemia (with the presence of Burr cells, schistocytes, spherocytes, or helmet cells), mild to severe thrombocytopenia
- Increased reticulocyte count
- Increased bilirubin and lactic dehydrogenase (LDH) levels
- Negative Coombs' test (except in cases of *S. pneumoniae* infection)
- Leukocytosis with left shift
- Hyponatremia
- Hyperkalemia
- Hyperphosphatemia
- Metabolic acidosis

Nursing Management

Nursing management of the child with HUS focuses on close observation and monitoring of the child's status. Institute and maintain contact precautions to prevent spread of *E. coli* O157:H7 to other children (bacteria are shed for up to 17 days after resolution of the diarrhea). Close attention must be paid to fluid volume status. Prevention of HUS is also an important nursing function.

Maintaining Appropriate Fluid Volume Balance

Maintain strict intake and output monitoring and recording to evaluate the progression toward renal failure. Carefully monitor intravenous infusions and blood chemistries. Administer diuretics as ordered. Assess blood pressure frequently and report elevations to the physician. Administer antihypertensives as ordered and monitor their effectiveness. Encourage adequate nutritional intake within the constraints of prescribed dietary restrictions. Monitor for bleeding as well as for fatigue and pallor. Follow the institutional protocol for transfusion of packed red blood cells and/or platelets (platelets are usually transfused only if active bleeding or severe thrombocytopenia occurs). Report progressive deterioration in laboratory findings to the physician. About 50% of children with HUS will require dialysis for at least several days.

Preventing HUS

Proper hand washing is necessary. Teach children to wash their hands after using the bathroom, before eating, and after petting farm animals. Encourage the use of "swim diapers," which contain feces, for children who are not toilet trained. Teach parents to thoroughly cook all meats to a core temperature of 155° F, or until the meat is gray or brown throughout and the juices from the meat are clear rather than pink. Wash all fruits and vegetables thoroughly. Ensure that drinking water and water used for recreation are appropriately treated. Avoid unpasteurized dairy products and fruit juices (including cider).

RENAL FAILURE

Renal failure is a condition in which the kidneys cannot concentrate urine, conserve electrolytes, or excrete waste products. As in adults, renal failure in children may occur as an acute or chronic condition. Some cases of acute renal failure resolve without further complications, while dialysis is necessary in other children. When acute renal failure continues to progress, it becomes chronic (also known as end-stage renal disease [ESRD]). Dialysis and kidney transplantation are treatment modalities used for ESRD.

Acute Renal Failure

Acute renal failure is defined as a sudden, often reversible, decline in renal function that results in the accumulation of metabolic toxins (particularly nitrogenous wastes) as well as fluid and electrolyte imbalance. Fluid overload may lead to hypertension, pulmonary edema, and congestive heart failure. Additional complications include hyperkalemia, metabolic acidosis, hyperphosphatemia, and uremia. In children, acute renal failure most commonly occurs as a result of decreased renal perfusion, as occurs in hypovolemic or septic shock. It may also occur in children with hemolytic anemia or as a result of nephrotoxicity from medications. Complications include anemia, hyperkalemia, hypertension, pulmonary edema, cardiac failure, and altered level of consciousness or seizures, and acute renal failure may also progress to a chronic state.

Therapeutic management is aimed at treating the underlying cause and managing the fluid and electrolyte disturbances, as well as decreasing blood pressure.

Take NOTE!

Medications commonly used in children can reduce renal function. Cephalosporins may cause a transient increase in BUN and creatinine. Truly nephrotoxic drugs often used in children include aminoglycosides, sulfonamides, vancomycin, and nonsteroidal anti-inflammatories (NSAIDs). Make sure that potentially nephrotoxic drugs are administered according to published safe guidelines (dosage, frequency, rate of administration).

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1381. Assessment finding pertinent to acute renal failure are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Nausea
- Vomiting
- Diarrhea
- Lethargy
- Fever
- Decreased urine output

Assess the child's current and past medical history for risk factors such as history of shock, trauma, burns, urologic abnormalities, renal disease, use of nephrotoxic medications, or severe blood transfusion reaction.

Physical Examination and Laboratory and Diagnostic Tests

Note decreased skin elasticity, dry mucous membranes, or edema. Auscultate lungs for crackles, which may occur with pulmonary edema. Document tachypnea. Note cardiac rhythm disturbances. Evaluate the child's level of consciousness. Laboratory tests will reveal increased serum creatinine levels and possible electrolyte disturbances, such as hyperkalemia or hypocalcemia. Urinalysis may reveal proteinuria or hematuria.

▶ *Take* NOTE!

Monitor the infant or child with renal failure carefully for signs of congestive heart failure, such as edema accompanied by bounding pulse, presence of an S3 heart sound, adventitious lung sounds, and shortness of breath.

Nursing Management

Nursing care focuses on managing hypertension, restoring fluid and electrolyte balance, and educating the family.

Managing Hypertension

Carefully monitor the child's blood pressure. Administer antihypertensives as prescribed. When a fast-acting drug such as nifedipine (Procardia) sublingually or labetalol intravenously is used, stay with the child and frequently monitor blood pressure. Immediately notify the physician if high blood pressure is resistant to medication and the blood pressure remains elevated.

Restoring Fluid and Electrolyte Balance

Monitor vital signs frequently and assess urine specific gravity. Maintain strict records of intake and output. Administer diuretics as ordered. When urine output is restored, diuresis may be significant. Monitor for signs of hyperkalemia (weak, irregular pulse; muscle weakness; abdominal cramping) and hypocalcemia (muscle twitching or tetany). Administer polystyrene sulfonate (Kayexalate) as ordered orally, rectally, or through a nasogastric tube to decrease potassium levels. Kayexalate removes potassium primarily by exchanging sodium for it, which is then eliminated in the feces. Administer packed red blood cell transfusions as ordered (may need to be followed by a dose of diuretic). Dialysis may become necessary if oliguria is sustained and leads to significant fluid overload, the electrolyte imbalance reaches dangerous levels, or uremia results in depression of the central nervous system.

Providing Family Education

Educate the family about the plan of care and the need for fluid restriction if ordered. Instruct the family to save all voids for observation and measurement by the nurse. Provide education about the use of dialysis if relevant.

End-Stage Renal Disease

End-stage renal disease (ESRD) is chronic renal failure requiring long-term dialysis or renal transplantation. Chronic renal failure in children most often results from congenital structural defects such as obstructive uropathy. It may also be caused by an inherited condition such as familial nephritis or may result from an acquired problem such as glomerulonephritis; it may follow an infectious process such as pyelonephritis or HUS. This is in contrast to chronic renal failure in adults, which primarily results from diabetes or hypertension. Uremia, hypocalcemia, hyperkalemia, and metabolic acidosis occur. Complications of ESRD are many. Uremic toxins deplete erythrocytes and the failing kidneys cannot produce erythropoietin, so severe anemia results. Hypertension is common and heart failure may occur. Hypocalcemia results in renal rickets (brittle bones). Growth is retarded and sexual maturation may be delayed or absent. Many children with ESRD experience depression, anxiety, impaired social interaction, and poor self-esteem. See Healthy People 2010.

Nursing Assessment

For a full description of the assessment phase of the nursing process refer to page 1381. Assessment finding pertinent to ESRD are discussed below.

HEALTHY PEOPLE 2010

Objective	Nursing Significance
Reduce the rate of new cases of end-stage renal disease (ESRD).	• Encourage compliance with medical regimens related to urinary tract disorders in order to prevent progression to chronic renal failure

Health History

Explore the health history for low birthweight (associated with kidney dysfunction and anatomic alterations), poor growth (weight, length/height, and head circumference), and regimen of dialysis. Note decreased appetite or energy level, dry or itchy skin, or bone or joint pain.

Physical Examination and Laboratory and Diagnostic Tests

Perform a thorough physical assessment, noting any abnormalities (may vary from child to child). If present, assess the peritoneal catheter site for absence of drainage, bleeding, or redness. If the child undergoes hemodialysis, assess the fistula or graft site for the presence of a bruit and a thrill. Laboratory tests may reveal low hemoglobin and hematocrit, increased serum phosphorus and potassium levels, and decreased sodium, calcium, and bicarbonate levels. BUN, uric acid, and creatinine levels will be elevated. A 24-hour urine creatinine clearance test will show increased amounts of creatinine in the urine, reflecting decreasing kidney function.

▶ *Take* NOTE!

Carefully assess children with ESRD for worsening uremia or metabolic acidosis. Uremia may result in central nervous system symptoms such as headache or coma, or gastrointestinal or neuromuscular disturbances. Metabolic acidosis causes lethargy, dull headache, and confusion.

Nursing Management

Nursing goals for the child with ESRD include promoting growth and development, removing waste products and maintaining fluid balance via dialysis, encouraging psychosocial well-being, and supporting and educating the family.

Promoting Growth and Development

Encourage the child to choose foods he or she likes that are within the imposed dietary restrictions. Daily protein requirements for adequate growth range from 0.9 to 1.5 grams of protein per kilogram of weight. Sodium and/or potassium restrictions may also be necessary. Enforce fluid restrictions if prescribed. Administer medications such as erythropoietin, growth hormone, and vitamin and mineral supplements to augment nutritional status and promote growth. Table 42.2 lists medications and supplements used to support growth.

Encouraging Psychosocial Well-Being

The child with chronic renal failure and particularly ESRD often suffers from depression and anxiety. Refer children and their families to the hospital social worker or counselor as needed for depression or anxiety issues. The chronic need for dialysis (daily with peritoneal dialysis or three or four times per week with hemodialysis) confers long-term stress on the child and family. The child usually demonstrates poor growth and often suffers from body image disturbance. Frequent medical appointments and hospitalizations interfere with the child's scholastic achievements. Introduce the child to other children with ESRD (this often happens anyway at the hemodialysis center).

Ensure that the family is aware of financial and support resources within the community (refer them to the National Kidney Foundation at www.kidney.org). The American Kidney Fund (www.kidneyfund.org) provides financial aid for kidney patients and summer camps for children with renal problems. Camp is an excellent way for children to demonstrate that they have mastered some of the loss-of-control issues related to their disease.

Several websites provide forums for children and teens with kidney failure or transplantation so they can learn about their disease, access resources, and/or communicate with other children. Two of them are:

- www.kidskare.org/: created by children, for children; contains information about organ donation and transplantation
- www.transweb.org: contains information about transplantation and donation

Dialysis and Transplantation

Peritoneal dialysis or hemodialysis is required on a long-term basis for children with chronic renal failure or ESRD. Once the child has progressed to ESRD, kidney transplan-

TABLE 42.2 MEDICATIONS AND SUPPLEMENTS COMMONLY USED TO TREAT ESRD COMPLICATIONS

Medication or Supplement	Purpose
Vitamin D and calcium	Correction of hypocalcemia and hyperphosphatemia
Ferrous sulfate	Treatment of anemia
Bicitra or sodium bicarbonate tablets	Correction of acidosis
Multivitamin	Augment nutritional status
Erythropoietin injections	Stimulate red blood cell growth
Growth hormone injections	Stimulate growth in stature

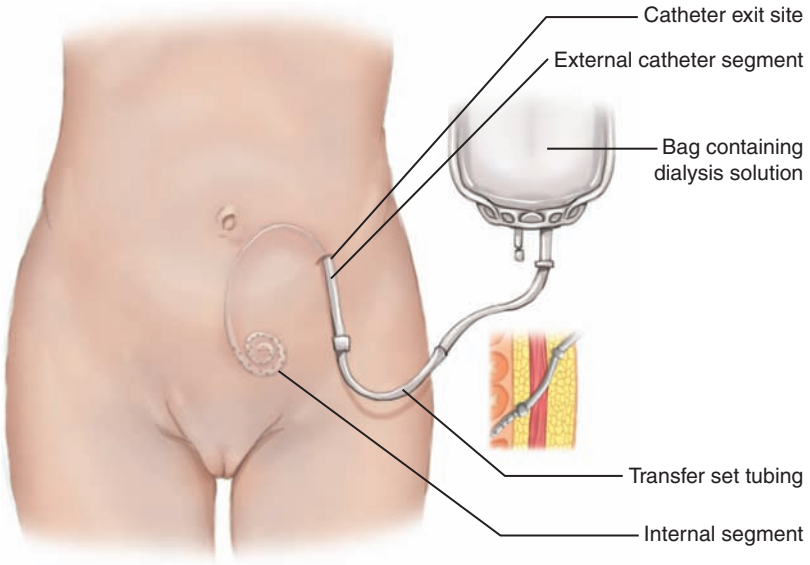

FIGURE 42.8 The peritoneal dialysis catheter is tunneled under the skin into the peritoneal cavity.

tation is needed for the child to progress with growth and development.

Peritoneal Dialysis

Peritoneal dialysis uses the child's abdominal cavity as a semipermeable membrane to help remove excess fluid and waste products (Figs. 42.8 and 42.9). The parent or caregiver performs peritoneal dialysis at home after completing a training course. The process is either completed overnight with the use of a machine (continuous cyclic peritoneal dialysis) or in increments throughout the day for a total of 4 to 8 hours (continuous ambulatory peritoneal dialysis). Comparison Chart 42.1 compares these two methods of peritoneal dialysis.

The advantages of peritoneal dialysis over hemodialysis include improved growth as a result of more dietary freedom, increased independence in daily activities, and a steadier state of electrolyte balance. However, the risk for infection (peritonitis and sepsis) is a continual concern with peritoneal dialysis. Dialysate exchange proto-

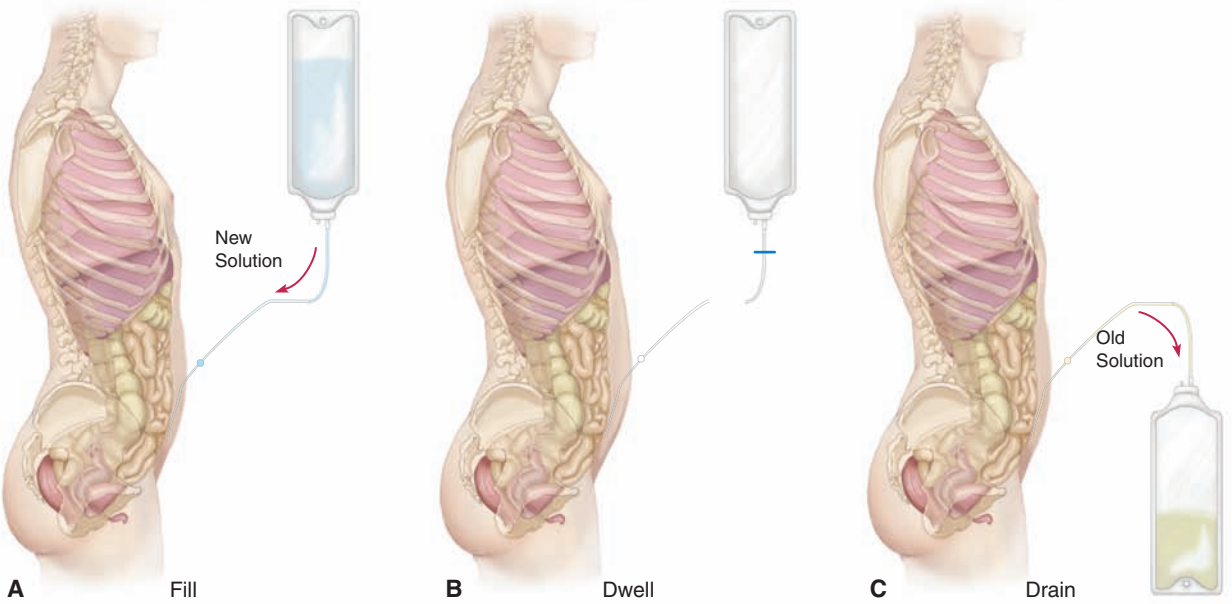

FIGURE 42.9 (**A**) During the "fill" phase of peritoneal dialysis, dialysate fluid is instilled into the peritoneal cavity. (**B**) During the "dwell" phase, the child may be up out of bed with the empty dialysate bag folded up with the tubing under his clothing. (**C**) During the "drain" phase, the old dialysate is drained from the peritoneum by gravity, bringing with it waste products and excess fluid. The dialysate bags are weighed prior to filling and after draining to determine the amount of fluid removed from the child.

COMPARISON CHART 42.1 METHODS OF PERITONEAL DIALYSIS

	Continuous Ambulatory Peritoneal Dialysis (CAPD)	Continuous Cyclic Peritoneal Dialysis (CCPD)
When performed	Throughout the day, with exchanges every 3 to 6 hours. Fluid is usually allowed to dwell overnight to allow child to sleep.	Usually overnight while child is sleeping
Method	Manual instillation and draining and changing of dialysate bags with each exchange	Automated via CCPD machine; bags and tubing are attached when started, then disconnected in the morning
Dwell time	3 to 6 hours	Usually 30 minutes to 1 hour
Mobility	Allows for mobility and permits child to participate in activities between exchanges	Child is confined to bed during the night while CCPD is ongoing but completely mobile while off CCPD during the day.

cols, care of the catheter in the abdomen, and dressing changes must all be performed using sterile technique to avoid introducing microorganisms into the peritoneal cavity. Box 42.3 lists additional risks associated with peritoneal dialysis.

Hemodialysis

Hemodialysis removes toxins and excess fluid from the blood by pumping the child's blood through a hemodialysis machine and then reinfusing the blood into the child. Needles to remove and reinfuse the blood are inserted into an arteriovenous fistula or graft, usually located in the child's arm (Figs. 42.10 and 42.11).

Hemodialysis frees the parent from the need to perform daily dialysis, but the procedure, which takes 3 to 6 hours, must be done two to four times per week (usually three) at a pediatric hemodialysis center. This requires time away from school and other activities for the child and from work and other family responsibilities for the parent. Since hemodialysis is usually performed only every other day, larger amounts of waste products build up in the child's blood (uremia), placing the child at higher risk for seizures. The access site may become infected, and occlusion is also possible. The child must follow a stricter diet between hemodialysis treatments, though dietary restrictions are usually lifted while the child is actually undergoing the treatment.

BOX 42.3 **Risks Associated with Peritoneal Dialysis**

- Hypertension and other cardiac complications
- Seizures
- Obstructed catheter
- Dialysate leakage
- Hyperglycemia
- Increased triglyceride levels
- Increased protein loss
- Parental stress and burnout related to repetitive nature of daily intervention

Nursing Assessment

Refer to the section on nursing assessment of the child with chronic renal failure/ESRD, as it is similar to assessment of the child undergoing dialysis. Assess for alterations in blood pressure and laboratory values following dialysis. Monitor for signs and symptoms of infection.

Assess the child receiving peritoneal dialysis for toleration of the fluid volume instilled within the peritoneum. The abdomen will remain distended while the fluid is indwelling and will be significantly flatter when the fluid is drained. Assess the Tenckhoff catheter site for signs of infection. Monitor the child's temperature. Inspect the dialysate effluent for fibrin or cloudiness, which may indicate infection. Weigh the child daily (in the drain phase if on peritoneal dialysis).

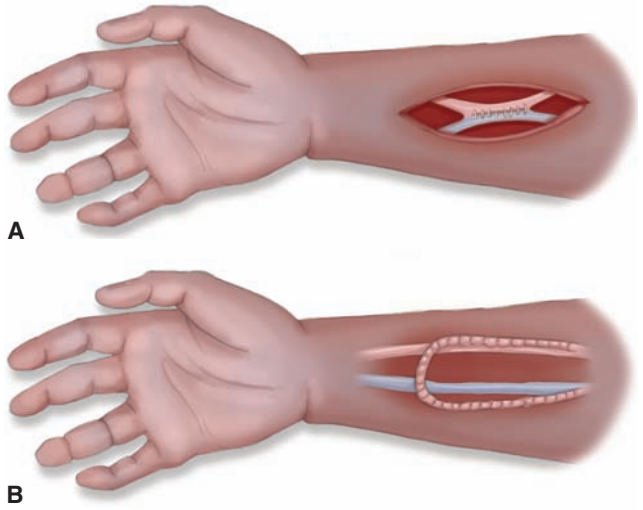

FIGURE 42.10 (**A**) Arteriovenous fistula. (**B**) Arteriovenous graft.

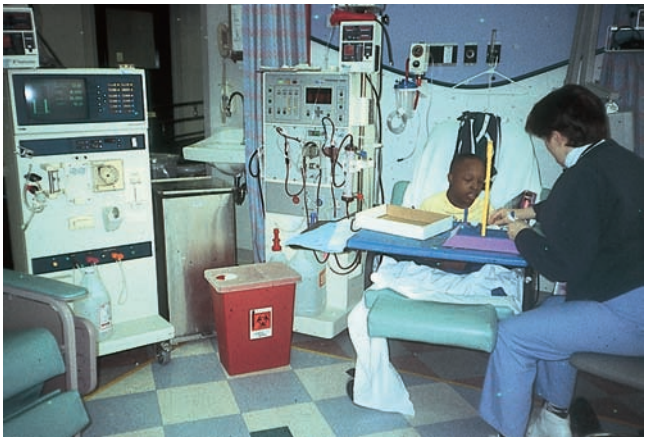

FIGURE 42.11 Pediatric hemodialysis via arteriovenous fistula or graft in left arm.

HEALTHY PEOPLE 2010

Objective	Nursing Significance
Increase the proportion of new hemodialysis patients who use arteriovenous fistulas as the primary mode of vascular access. Increase the proportion of dialysis patients registered on the waiting list for transplantation.	• Educate families about the benefits of an arteriovenous fistula over other methods of hemodialysis access. • Advocate for the patient to obtain an arteriovenous fistula. • Educate families about transplantation, and if no living-related match is available, encourage the family to seek placement on the organ transplant waiting list.

For the child who receives hemodialysis, assess the arteriovenous fistula or graft site with each set of vital signs. Auscultate the site for the presence of a bruit and palpate for the presence of a thrill. Notify the physician immediately if either is absent.

▶ Take NOTE!

Avoid taking blood pressure, performing venipuncture, or using a tourniquet in the extremity with the arteriovenous fistula or graft: these procedures may cause occlusion and subsequent malfunction of the fistula or graft. Teach parents and children to inform all health care providers they come in contact with about the presence of the fistula or graft.

Nursing Management

Both peritoneal dialysis and hemodialysis are performed by specially trained and certified nurses. The general pediatric nurse's role is related to the ongoing care of the child. The child undergoing peritoneal dialysis usually is allowed a more liberal diet and intake of fluid than the child undergoing hemodialysis. Peritoneal dialysis removes waste and excess fluids on a daily basis, whereas hemodialysis occurs about every other day. Most routine medications are withheld on the morning that hemodialysis is scheduled, since they would be filtered out through the dialysis process anyway. Administer these medications as soon as the child returns from the dialysis unit. See Healthy People 2010.

Renal Transplantation

Renal transplantation is the optimal treatment for ESRD and offers the best opportunity for the child to live a normal life. Vigilant medication administration is necessary after the transplant to prevent organ rejection. The child may achieve 40% to 80% renal function with the transplant and demonstrate improved growth, enhanced cognitive development, and improved psychosocial development and quality of life (Milliner, 2004).

Kidneys are obtained from a cadaver (a patient declared brain-dead who had previously given consent to organ donation) or from a blood relative (living-related). The transplanted kidney must match the child's blood type and the child's human leukocyte antigens (HLA). The cadaver kidney or living-related kidney is implanted surgically in the abdomen and the blood vessels are anastomosed to the aorta and superior vena cava.

Generally, living-related transplants have a decreased rejection rate compared to cadaver transplants. Living-related kidney donation and subsequent transplantation can be planned ahead and scheduled in advance. In contrast, cadaver kidneys become available suddenly, leaving less time for preoperative preparation. For either type, last-minute blood tissue typing is required before the final decision is made to move forward with transplantation. Often the child's native kidneys are removed before or at the time of the renal transplant because of their association with hypertension in the child.

▶ Take NOTE!

Cadaver kidneys are allocated to potential recipients based on the age of the renal failure patient, the time that he or she has been awaiting a transplant, blood type, HLA antibody matching, panel reactive antibodies, and region of the country (so that the donated kidney can be received expeditiously).

Nursing Assessment

A thorough physical assessment is warranted for any renal transplant patient, whether in the initial postoperative period, at a clinic visit, or when admitted to the hospital to rule out transplant rejection. Note recent health history, medications and their doses, and any symptoms the child has been having. In the initial postoperative period, assess the incision for redness, edema, or drainage; if any of these signs of infection or rejection occur, notify the transplant surgeon and nephrologist immediately. Monitor blood pressure and other vital signs closely. Document resolution of edema. Record intake and output accurately. Assess for signs and symptoms of transplant rejection such as malaise, fever, unexplained weight gain, or pain over the transplant area.

Nursing Management

Postoperative care focuses on preventing rejection, monitoring renal function, maintaining fluid and electrolyte balance, and educating the child and family.

▶ *Take* NOTE!

Encourage the child with a renal transplant to wear a medical alert necklace or bracelet, and urge the parents to inform community emergency services of the child's transplant status.

Preventing Rejection and Promoting Renal Function

Administer immunosuppressants accurately and in a timely fashion. Obtain and monitor serum levels of these medications per protocol. Immediately report significant alterations in vital signs or edema at the surgical site, as they may indicate transplant rejection. Maintain strict documentation of intake and output. Once adequate urine output is established, intake is usually liberalized.

Educating the Child and Family

Develop a schedule to cluster care so that the child may receive the rest needed for recovery despite the many and frequent assessments and interventions. With the family, develop a medication schedule that will be compatible with the family's life at home as well as the restrictions related to some medications. Begin teaching with the family as soon as the child's condition is stable. Accurate medication administration and home monitoring are necessary to prevent rejection. The child may return to school when discharged from the hospital, but the family will need to communicate closely with the school nurse about the child's immunosuppressed status. The American Nephrology Nurses Association has developed a renal transplant fact sheet that can be shared with the school nurse (available at www.annanurse.org).

▶ *Take* NOTE!

Tell the parents to inform their primary care provider about the child's long-term corticosteroid use and/or immunosuppressed status, as the child should not receive any live vaccines.

Reproductive Organ Disorders

A number of disorders may occur within the female or male genitalia and internal reproductive organs in children. These problems may be structural or infectious.

FEMALE DISORDERS

Disorders of the female reproductive organs that occur in children and adolescents include structural disorders, infectious disorders, and menstrual disorders.

Labial Adhesions

Labial adhesion or labial fusion is partial or complete adherence of the labia minora (Fig. 42.12). UTI may result from urinary stasis behind the labia; if the adhesions are left untreated, the vaginal orifice may become inaccessible, presenting difficulty with sexual intercourse in the future.

FIGURE 42.12 Labial adhesions. Note fusion of the upper portion of the labia minora.

Nursing Assessment

Younger girls have a higher risk of adhesions (3 months to 4 years). Assess the history for dysuria or urinary frequency. Inspect the genitalia for fusion or adherence of the labia minora.

Nursing Management

Administer topical estrogen cream as prescribed, usually once or twice daily. Teach the parents to continue cream application until the labia separate. Encourage use of petroleum jelly daily for 1 month following labial separation to prevent recurrence of adhesion.

Vulvovaginitis

Vulvovaginitis is inflammation of the vulva and vagina. Inflammation may occur as a result of bacterial or yeast overgrowth or from chemical factors such as bubble bath, soaps, or perfumes found in personal care products. Poor hygiene may also cause vulvovaginitis. Tight clothing may cause a heat rash in the perineal area. Persistent scratching of the irritated area may result in the complication of superficial skin infection.

Nursing Assessment

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history may include itching or burning in the perineal area. Explore the client's current and past medical history for risk factors, which may include:

- Young age (toilet-trained preschooler)
- Poor hygiene
- Sexual activity
- Immune disorders
- Diabetes mellitus

Inspect the perineum for redness, edema, irritation, rash, or vaginal discharge (note color, consistency, and odor).

Nursing Management

Teach appropriate hygiene (daily and toileting). Girls (or their parents) should wash the genital area thoroughly on a daily basis with mild soap and water. Rinse the area well. Encourage girls to wipe after urinating and after bowel movements to wipe in a front-to-back motion. The girl should wear cotton underwear and should change it at least once a day. Administer topical or oral medications as ordered. Table 42.3 lists treatments related to specific types of vulvovaginitis.

MALE DISORDERS

Male reproductive disorders include structural disorders and disorders caused by infection or inflammation. Circumcision will also be discussed below.

Phimosis and Paraphimosis

In phimosis, the foreskin of the penis cannot be retracted. Although this is normal in the newborn, it can be pathologic later. Over time, the prepuce (foreskin) naturally becomes retractable. Local irritation, balanitis, or UTI may occur if urine is retained within the foreskin after voiding. Paraphimosis (Fig. 42.13) is a more serious disorder characterized by retraction of the phimotic prepuce, which causes a constricting band behind the glans of the penis and results in incarceration if left untreated.

TABLE 42.3 **Vulvovaginitis: Types and Treatments**

Cause	Assessment Findings	Treatment
Unhygienic practices	Irritation of labia and vaginal opening May have foul brownish-green discharge if infected with bacteria from rectum	Good hygiene Sometimes a mild anti-inflammatory cream is prescribed. Assess for signs and symptoms of UTI, which may occur as a complication.
Candida albicans	Red bumpy perineal rash in infants White cottage-cheese–like discharge Intense itching	Antifungal cream or vaginal suppository Prevent by ingesting probiotics (found in yogurt and kefir) daily and supplementing with a probiotic such as Lactinex when taking antibiotics.
Bordetella, Gardnerella	Thin gray vaginal discharge with fishy odor	Flagyl (metronidazole) orally
Trichomonas vaginalis	Foul yellow-gray or green vaginal discharge	Flagyl (metronidazole) orally. Sexually transmitted, so can be prevented with the use of condoms.

FIGURE 42.13 Paraphimosis: note the swollen prepuce.

Topical steroid cream applied twice a day for 1 month may be prescribed for phimosis. Paraphimosis requires reduction of the prepuce or a small dorsal incision to release the foreskin. Circumcision may be used to treat either condition.

Nursing Assessment

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include:

- Irritation or bleeding from the opening of the prepuce (phimosis)
- Dysuria (phimosis)
- Pain (paraphimosis)
- Swollen penis (paraphimosis)

Determine the onset of symptoms and inspect the penis for irritation, erythema, edema, or discharge.

▶ *Take NOTE!*

A swollen, reddened penis (paraphimosis) is a medical emergency and can quickly result in necrosis of the tip of the penis if left untreated.

Nursing Management

Apply topical steroid medication as prescribed for phimosis, following gentle retraction to stretch the foreskin back. Topical vitamin E cream may also help to soften the phimotic ring. When surgical intervention is necessary, provide routine postprocedural care and pain management (refer to the section on circumcision below). Teach the parents and uncircumcised boy proper hygiene, which will help to prevent phimosis and paraphimosis (Teaching Guidelines 42.2).

TEACHING GUIDELINES 42.2

Hygiene in the Uncircumcised Male

- The foreskin does not normally retract in the newborn boy, so do not force it to do so.
- Change the diaper frequently and wash the penis daily with water and mild soap.
- When the infant is older and the foreskin easily retracts, gently retract the foreskin and clean around the glans with water and mild soap once a week.
- Dry the area prior to replacing the foreskin.
- Always replace the foreskin after retraction.
- Teach the preschool-age boy to retract the foreskin and clean the penis during each bath or shower.

Circumcision

Circumcision is the removal of the excess foreskin of the penis. Some newborn boys are circumcised shortly after birth before going home from the hospital. Some parents elect not to have their newborn boy circumcised at that time but may desire it later. Neonatal circumcision may be performed in the newborn nursery, hospital unit treatment room, or outpatient office. Circumcision is indicated later for the conditions of phimosis and paraphimosis. Circumcision done after the newborn period usually requires general anesthesia.

The benefits of circumcision include a decreased incidence of UTI, sexually transmitted diseases, acquired immune deficiency syndrome, and penile cancer, and in female partners a decreased occurrence of cervical cancer. Complications of circumcision include alterations in the urinary meatus, unintentional removal of excessive amounts of foreskin, or damage to the glans penis.

Whether to circumcise or not is a personal decision and often based on religious beliefs or social or cultural customs. Nurses should support and educate the parents in either case.

Nursing Assessment

Prior to the procedure, assess for normal placement of the urinary meatus on the glans penis (in boys with hypospadias, circumcision should be delayed until evaluation by the pediatric urologist). After the circumcision, assess for redness, edema, or active bleeding. Note signs of infection, such as purulent drainage. Assess pain level.

Nursing Management

Nursing care of the boy undergoing circumcision focuses on managing pain, providing postprocedural care, and educating the parents.

Managing Pain

Whether circumcision is performed in the obstetric area of the hospital before newborn discharge or in the outpatient setting at a few days of age, pain management during the procedure must not be neglected. Advocate for appropriate pain management for the infant undergoing circumcision. The American Academy of Pediatrics (AAP) recommends using a subcutaneous ring block with lidocaine or a dorsal nerve block to the penis. The AAP also recommends the use of EMLA (eutectic mixture of local anesthetic) cream topically to decrease pain during the circumcision. Playing calming music during the procedure may also help to soothe the infant, providing distraction. A sucrose-dipped pacifier may also be used as adjuvant therapy for pain management. To increase a sense of comfort during the procedure, restrain the infant in a padded circumcision chair with blankets covering the legs and upper body. This allows the infant to be in a semiupright position during the procedure while still allowing for a sterile procedural field. If a padded restraint chair is not available, provide atraumatic care by padding the circumcision board and covering the infant as previously described.

Providing Postprocedural Care

Usual care after circumcision depends on the type of appliance used (Gomco or Mogan clamp or Plastibell apparatus). Cleanse the penis with clear water for the first few days and avoid using alcohol-containing wipes. To avoid irritation to the penis, fasten diapers loosely. Notify the physician if excessive redness, active bleeding, or purulent discharge occurs. Assess for the first void following the procedure, or if performed in the outpatient setting instruct parents to call the physician if the infant has not voided by 6 to 8 hours after the circumcision. Apply antibiotic ointment or petroleum jelly to the penile head with each diaper change as prescribed, based on the circumcision method used and the preference of the health care provider.

▶ Take NOTE!

If excess bleeding occurs after the circumcision, apply direct pressure and notify the health care provider immediately.

Educating the Parents

Instruct parents to give sponge baths until the circumcision is healed. Describe the normal granulation tissue that will be present during the healing process. Teach parents to apply ointment or petroleum jelly if indicated. Instruct the parents to call the health care provider if any of the following occur:

- The infant does not urinate within 6 to 8 hours after the procedure.
- Heavy bleeding occurs (more than small spots on the diaper or bleeding that requires direct pressure to stop it).
- There is purulent or serous drainage from the circumcised area.
- There is redness or swelling of the penile shaft.

▶ Take NOTE!

If the Plastibell is used, teach parents NOT to use petroleum jelly, as it may cause the ring to be dislodged. A yellowish crust may form that should be allowed to fall off on its own after several days.

Cryptorchidism

Cryptorchidism (also known as undescended testicles) occurs when one or both testicles do not descend into the scrotal sac. Ordinarily the testes, which in the fetus develop in the abdomen, make their descent into the scrotal sac during the seventh month of gestation. The cause for this failure to descend may be mechanical, hormonal, chromosomal, or enzymatic. The disorder may occur unilaterally or bilaterally. Up to 4% of term male infants and as many as 30% of all preterm male infants exhibit cryptorchidism (Burns et al., 2004).

Complications associated with cryptorchidism that is allowed to progress into the school-age years include sterility and an increased risk for testicular cancer in adolescence or the young adult years. Therapeutic management is surgical. An orchiopexy is performed to release the spermatic cord, and the testes are then pulled into the scrotum and tacked into place.

Nursing Assessment

Explore the health history for risk factors such as:

- Prematurity
- First-born child
- Cesarean birth
- Low birthweight
- Hypospadias

Palpate for the presence (or absence) of both testes in the scrotal sac.

▶ Take NOTE!

A retractile testis is one that may be brought into the scrotum, remains for a time, and then retracts back up the inguinal canal. This should not be confused with true cryptorchidism.

Nursing Management

If the testes are not descended by 6 months of age, the infant should be referred for surgical repair. The AAP recommends that orchiopexy be performed by 1 year of age. Postoperatively, observe the incision for signs of bleeding or infection.

Hydrocele and Varicocele

Hydrocele (fluid in the scrotal sac) is usually a benign and self-limiting disorder. It is usually noted early in infancy and often resolves spontaneously by 1 year of age. Varicocele (a venous varicosity along the spermatic cord) is often noted as a swelling of the scrotal sac. Complications of varicocele include low sperm count or reduced sperm motility, which can result in infertility.

Nursing Assessment

Elicit a description of the present illness and chief complaint. The boy with hydrocele will have an enlarged scrotum that may decrease in size when he is lying down. Inspect the scrotum for a fluid-filled appearance.

The boy with varicocele will have a mass on one or both sides of the scrotum and bluish discoloration. Inspect the scrotum for masses; the spermatic vein feels worm-like on palpation. The boy with varicocele may have pain.

Nursing Management

Both hydrocele and painless varicocele require watchful waiting, as these conditions will usually resolve spontaneously. If they do not resolve, or if the difference in testicular volume is marked in the boy with varicocele, refer the child to a urologist, as surgery may be indicated. Reassure parents that hydrocele is not associated with the development of infertility. Varicocele may lead to infertility if left untreated, so instruct parents to seek care if pain occurs or if there is a large difference in testicular size. Either condition may be surgically corrected on an outpatient basis. Provide routine postoperative care following either surgery.

Testicular Torsion

In testicular torsion, a testicle is abnormally attached to the scrotum and twisted. It requires immediate attention because ischemia can result if the torsion is left untreated, leading to infertility. Testicular torsion may occur at any age but most commonly occurs in boys aged 12 to 18 years (Burns et al., 2004).

Nursing Assessment

Elicit a description of the present illness and chief complaint. Signs and symptoms of testicular torsion include sudden, severe scrotal pain. Inspect the affected side for significant swelling, which may appear hemorrhagic or blue-black.

Nursing Management

Surgical correction is necessary immediately. Administer pain medication prior to surgery. Reassure the child and family that surgery will alleviate the problem and is performed to restore adequate blood flow to the testicle. After surgical repair, provide routine postoperative care.

▶ *Take* NOTE!

Testicular torsion is considered a surgical emergency, as necrosis of the testis may occur and gangrene may set in.

Epididymitis

Epididymitis (inflammation of the epididymis) is caused by infection with bacteria. It is the most common cause of pain in the scrotum. It rarely occurs before puberty, but if it does it may occur as a result of a urethral or bladder infection related to a urogenital anomaly (Burns et al., 2004). Therapeutic management is directed toward eradicating the bacteria. If left untreated, a scrotal abscess, testicular infarction, or infertility may occur.

Nursing Assessment

Note history of painful swelling of the scrotum, which may be gradual or acute. If the boy is sexually active, explore history of sexual encounters prior to the onset of symptoms. Document history of dysuria or urethral discharge. Note fever, which may last from days to weeks. On inspection, note edema and erythema of the scrotum. Gently palpate the scrotum for a hardened and tender epididymis. Note urethral discharge if present. Palpate the inguinal lymph nodes for enlargement. Urinalysis may be positive for bacteria and white blood cells. The culture of urethral discharge may be positive for a sexually transmitted infection such as gonorrhea or *Chlamydia*. The complete blood count may reveal an elevated white blood cell count.

Nursing Management

Encourage the boy to rest in bed with the scrotum elevated. Ice packs to the scrotum may help with pain relief. Administer pain medications such as NSAIDs or other analgesics as needed.

Administer antibiotics as prescribed. Educate the boy and his family to complete the entire course of antibiotics as prescribed to eradicate the infection. Advise the child and family to notify the physician if the condition is not improving or if the pain and swelling worsen.

Key Concepts

- The urinary tract is immature in infants and young children, with a slower glomerular filtration rate and a decreased ability to concentrate urine and reabsorb amino acids compared with the adult.

- In children, chronic kidney disease is most often the result of congenital structural defects, or infectious, inflammatory, or immune processes that damage the kidney, whereas in adults it usually results from hypertension or diabetes.
- The short length of the urethra in girls and its proximity to the vagina and anus place the young girl at higher risk for the development of urinary tract infections compared with the adult.
- The expected urine output in the infant and child is 0.5 to 2 mL/kg/hour.
- Though present at birth, the reproductive organs do not reach functional maturity until puberty.
- Obtaining a clean or sterile urine specimen is necessary for accurate urine culture results.
- A urinary catheter must be inserted just prior to the voiding cystourethrogram.
- Close monitoring of serum blood counts and electrolytes is a critical component of nursing care related to renal disorders.
- Certain congenital urologic anomalies may require multiple surgeries as well as urinary diversion; urine drains through a stoma on the abdominal wall that is either pouched or catheterized.
- The treatment for nocturnal enuresis may include the use of desmopressin nasal spray and/or an enuresis alarm to train the child to awaken to the sensation of a filling bladder.
- Nephrotic syndrome results in significant proteinuria and edema.
- Acute glomerulonephritis most often follows a group A streptococcal infection and commonly results in hematuria, proteinuria, and hypertension.
- The most common cause of hemolytic-uremic syndrome is infection with *E. coli* O157:H7. It can be prevented by adequately cooking ground meat, washing hands and produce well, and making sure that an appropriate chemical balance is maintained in public recreational water sources such as swimming pools and water parks.
- Corticosteroids can cause gastrointestinal upset. If used on a long-term basis, they should be tapered rather than discontinued abruptly to avoid adrenal crisis.
- Children taking immunosuppressants for nephrotic syndrome or for renal transplant are at increased risk for the development of overwhelming infection.
- Peritoneal dialysis may be accomplished at home by the parent. Close attention to sterile technique is needed.
- Hemodialysis requires an arteriovenous fistula or graft that is accessed with needles three or four times per week at a hemodialysis center. This is disruptive to their academic, social, and family lives.
- Renal transplantation is the best option for the treatment of end-stage renal disease in children, but vigilant medication administration is needed to prevent organ rejection.
- Children with renal failure experience anemia, poor growth, depression, anxiety, and low self-esteem.
- The diet for a child with a renal disorder must be individualized according to prescribed sodium, fluid, and/or protein restrictions.
- Postoperative care for the child undergoing urologic surgery includes pain management, avoidance or treatment of bladder spasms, and monitoring of urine output.

Chapter Worksheet

Multiple Choice Questions

1. The nurse is performing patient education for the parents of an infant with bladder exstrophy. Which statement by the parents would indicate an understanding of the child's future care?

   a. "Care will be no different than that of any other infant."
   b. "My infant will only need this one surgery."
   c. "My child will wear diapers all his life."
   d. "We will need to care for the urinary diversion."

2. A 4-year-old girl presents with recurrent urinary tract infection. A prior workup did not reveal any urinary tract abnormalities. What is the priority nursing action?

   a. Obtain a sterile urine sample after completion of antibiotics.
   b. Teach appropriate toileting hygiene.
   c. Prepare the child for surgery to reimplant the ureters.
   d. Administer antibiotics intramuscularly.

3. A 5-year-old who had a renal transplant 9 months ago and has no history of chickenpox presents to the pediatric clinic for his vaccinations. Which is the most appropriate set to give?

   a. DTaP, IPV.
   b. DTaP, IPV, MMR, Varicella.
   c. DTaP, IPV, Varicella.
   d. IPV only.

4. When the nurse is caring for a child with hemolytic-uremic syndrome or acute glomerulonephritis and the child is not yet toilet trained, which action by the nurse would best determine fluid retention?

   a. Test urine for specific gravity.
   b. Weigh child daily.
   c. Weigh the wet diapers.
   d. Measure abdominal girth daily.

Critical Thinking Exercises

1. Devise a meal plan for a 5-year-old child with a renal disorder that requires a 2-g sodium restriction per day. Keep in mind the child's developmental level and feeding idiosyncrasies at this age.
2. Develop a discharge teaching plan for a 3-year-old with nephrotic syndrome who will be taking corticosteroids long term.
3. Devise a developmental stimulation plan for an 11-month-old who has had significant urinary tract reconstruction surgery and is facing a prolonged period of confinement to the crib.

Study Activities

1. In the clinical setting, compare the growth and development of two children the same age, one with chronic renal failure and one who has been healthy.
2. While caring for children in the clinical setting, compare and contrast the medical history, signs and symptoms of illness, and prescribed treatments for a child with nephrotic syndrome and one with acute glomerulonephritis.
3. Observe peritoneal dialysis in the hospital or hemodialysis in a hospital or outpatient center. Record observations about the children's psychosocial and developmental status.

CHAPTER 43

Nursing Care of the Child With a Neuromuscular Disorder

KEY TERMS

atrophy
clonus
contracture
dystrophy
hypertonicity
hypotonia
neurogenic
spasticity

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Compare differences between the anatomy and physiology of the neuromuscular system in children versus adults.
2. Identify nursing interventions related to common laboratory and diagnostic tests used in the diagnosis and management of neuromuscular conditions.
3. Identify appropriate nursing assessments and interventions related to medications and treatments used for childhood neuromuscular conditions.
4. Distinguish various neuromuscular illnesses occurring in childhood.
5. Devise an individualized nursing care plan for the child with a neuromuscular disorder.
6. Develop patient/family teaching plans for the child with a neuromuscular disorder.
7. Describe the psychosocial impact of chronic neuromuscular disorders on the growth and development of children.

Frederick Stevens, 4 years old, seems to be falling often and has started to have difficulty climbing the stairs on his own. His mother states, "Recently he hasn't been able to keep up with his 6-year-old sister when we're playing at the park. He usually ends up sitting on the bench with me." She is concerned about the changes she has seen in her son.

Wow

Enhancing a child's abilities may enhance his or her strength to overcome anything.

A variety of neuromuscular disorders may affect children, but the result of each is muscular dysfunction. Some of the disorders result from a neurologic insult such as trauma or hypoxia to the brain or spinal cord. Others occur as a result of genetic dysfunction or structural abnormality. Still others may be autoimmune in nature, often following a simple viral infection. Many of the neuromuscular disorders are chronic, lasting the child's entire life and resulting in handicaps.

The nurse caring for a child with neuromuscular dysfunction plays an important role in the management of these disorders. Not only must the nurse provide direct intervention in response to health alterations that result, but the nurse is often part of the larger multidisciplinary team and may serve as the coordinator of many specialists or interventions. Understanding the most common responses to these disorders gives the nurse the foundation required to plan care for any child with any neuromuscular disorder.

Variations in Pediatric Anatomy and Physiology

Neuromuscular disorders in children may occur as a congenital malformation or a genetic disorder that is present from birth but may not be identified until later in childhood or adolescence. They may also result from trauma or hypoxia or develop following a viral illness. The neurologic and musculoskeletal systems in infants and children are immature compared with adults, placing them at increased risk for the development of a neuromuscular disorder.

Brain and Spinal Cord Development

Early in gestation, around 3 to 4 weeks, the neural tube of the embryo begins to differentiate into the brain and spinal cord. If the fetus suffers infection, trauma, malnutrition, or teratogen exposure during this critical period of growth and differentiation, brain or spinal cord development may be altered. Compared with the adult, the child's spine is very mobile, especially the cervical spine region, resulting in a higher risk for cervical spine injury. The premature infant's central nervous system is less mature than the term newborn's. Such immaturity in the preterm infant places him or her at a higher risk of central nervous insult within the neonatal period, which may result in delayed motor skill attainment or cerebral palsy.

Myelinization

Though development of the structures of the nervous system is complete at birth, myelinization is incomplete. Myelinization continues to progress and is complete by about 2 years of age. Myelinization proceeds in a cephalocaudal and proximodistal fashion, allowing the infant to gain head and neck control before becoming able to control the trunk and the extremities. As myelinization proceeds, the speed and accuracy of nerve impulses increase.

Muscular Development

The muscular system, including tendons, ligaments, and cartilage, arises from the mesoderm in early embryonic development. At birth (term or preterm), the muscles, tendons, ligaments, and cartilage are all present and functional. The newborn infant is capable of spontaneous movement but lacks purposeful control. Full range of motion is present at birth. Healthy infants and children demonstrate normal muscle tone; hypertonia or **hypotonia** is an abnormal finding. Deep tendon reflexes are present at birth and are initially brisk in the newborn and progress to average over the first few months. Sluggish deep tendon reflexes indicate an abnormality. As the infant matures and becomes mobile, the muscles develop further and become stronger. The adolescent boy, in response to testosterone release, experiences a growth spurt, particularly in the trunk and legs, and develops bulkier muscles at that time.

Common Medical Treatments

A variety of medications as well as other medical treatments are used to treat neuromuscular disorders in children. Most of these treatments will require a physician's order when the child is in the hospital. The most common treatments and medications are listed in Common Medical Treatments 43.1 and Drug Guide 43.1. The nurse caring for the child with a neuromuscular disorder should become familiar with what these procedures are and how they work as well as common nursing implications related to use of these modalities.

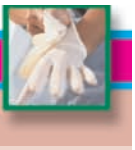
Nursing Process Overview for the Child With a Neuromuscular Disorder

Care of the child with a neuromuscular disorder includes assessment, nursing diagnosis, planning, interventions, and evaluation. There are a number of general concepts related to the nursing process that may be applied to neuromuscular dysfunction in children. From a general understanding of the care involved for a child with a neuromuscular disorder, the nurse can then individualize the care based on patient specifics.

Assessment

Assessment of neuromuscular dysfunction in children includes health history, physical examination, and laboratory and diagnostic testing.

COMMON MEDICAL TREATMENTS 43.1



Treatment	Explanation	Indication	Nursing Implications
Skeletal or cervical traction	Traction is used to immobilize the cervical spine. Halo traction will be applied in stable injuries and allows the patient greater mobility. Cervical traction is applied by a jacket-like apparatus, and the patient can get out of bed, use a wheelchair, and even ambulate.	To minimize or prevent trauma to the spinal cord	Monitor neurologic status closely. Assess for signs and symptoms of infection or impaired skin integrity. Provide appropriate pin site care.
Physical therapy, occupational therapy, or speech therapy	Physical therapy focuses on attainment or improvement of gross motor skills. Occupational therapy focuses on refinement of fine motor skills, feeding, and activities of daily living. Speech therapy is warranted for the child with a speech impairment or feeding difficulty related to oral muscular issues.	Cerebral palsy, spina bifida, spinal cord injury, muscular dystrophy, spinal muscular atrophy	Provide follow-through with prescribed exercises or supportive equipment. Success of therapy is dependent upon continued compliance with the prescribed regimen. Ensure that adequate communication exists within the interdisciplinary team.
Orthotics, braces	Adaptive positioning devices specially fitted for each child by the physical or occupational therapist or orthotist. Used to maintain proper body or extremity alignment, improve mobility, and prevent contractures.	Cerebral palsy, spinal cord injury, spina bifida, muscular dystrophy, spinal muscular atrophy	Provide frequent assessments of skin covered by the device to avoid skin breakdown. Follow the therapist's schedule of recommended "on" and "off" times. Encourage families to comply with use.

Remember Frederick, the 4-year-old who has been falling, having difficulty climbing stairs, and seems to tire easily when playing with his sister? What additional health history and physical examination assessment information should the nurse obtain?

Health History

The health history comprises past medical history, including the mother's pregnancy history, family history, and history of present illness (when the symptoms started and how they have progressed) as well as treatments used at home. The past medical history might be significant for prematurity, difficult birth, infection during pregnancy, changes in gait, falls, delayed development, or poor growth. Family history might be significant for neuromuscular disorders that are genetic. When eliciting the history of the present illness, inquire about the following:

- Changes in gait
- Recent trauma
- Poor feeding
- Lethargy
- Fever
- Weakness
- Alteration in muscle tone

Determine the child's history of attainment of developmental milestones. Note the age that milestones such as sitting, crawling, and walking were attained, and determine whether the pace of attainment of milestones has decreased. Some children may progress normally at first and then demonstrate decreased velocity of development of achievements or even loss of abilities. Obtain a clear description of weakness; is it fatigue, or is the child truly not as strong as he or she was in the past?

Physical Examination

Physical examination of the nervous and musculoskeletal systems consists of inspection, observation and palpation and should also include auscultation of the heart and lungs, as the function of these organs may be affected by certain neuromuscular conditions.

Inspection and Observation

Observe the infant or child playing with toys, crawling, or walking to obtain significant information about cranial

DRUG GUIDE 43.1 Common Drugs for Neuromuscular Disorders

Medication	Action/Indications	Nursing Implications
Benzodiazepines (diazepam, lorazepam)	Anticonvulsant; enhance the inhibition of GABA Used adjunctively for relief of skeletal muscle spasm associated with cerebral palsy and paralysis resulting from spinal cord injury	Monitor sedation level. Assess for improvements in spasticity.
Baclofen (oral or intrathecal)	Central-acting skeletal muscle relaxant; precise mechanism unknown Used to treat painful spasms and decrease spasticity in children with motor neuron lesions, such as cerebral palsy and spinal cord injury	Assess motor function. Monitor for a decrease in spasticity. Observe for mental confusion, depression, or hallucinations. Dosage must be tapered before discontinuing because withdrawal symptoms may occur.
Corticosteroids	Anti-inflammatory and immunosuppressive action Duchenne muscular dystrophy, myasthenia gravis, dermatomyositis	Administer with food to decrease GI upset. May mask signs of infection. Do not stop treatment abruptly or acute adrenal insufficiency may occur. Monitor for Cushing syndrome. Dosage may be tapered over time.
Botulin toxin	Neurotoxin produced by *Clostridium botulinum* that blocks neuromuscular conduction Relief of spasticity in cerebral palsy, occasionally for torticollis	Injected into the muscle by an advanced provider. May cause dry mouth.

nerve, cerebellar, and motor function. Observe the child's general appearance, noting any asymmetry in muscle development. Lack of use of extremities leads to muscular **atrophy**, so a shortened limb may indicate chronic hemiparesis. Note symmetry of spontaneous movement of extremities as well as facial muscles. Determine cranial nerve function. Inspect the spine for cutaneous abnormalities such as dimples or hair tufts, which may be associated with spinal cord abnormalities. Observe the child's level of consciousness (LOC), noting decrease or significant changes. Note presence of lethargy. Refer to Chapter 38 for a complete description of evaluation of LOC.

Motor Function. Observe spontaneous activity, posture, and balance, and assess for asymmetrical movements. In the infant, observe resting posture, which will normally be a slightly flexed posture. The infant should be able to extend extremities to a normal stretch. Note position of comfort of the infant's or child's neck.

Reflexes. Note sluggish or brisk deep tendon reflexes. Note persistence of primitive reflexes in the older infant or child, such as Moro or tonic neck. Assess for development of protective reflexes, which is often delayed in infants with motor disorders.

Sensory Function. Alterations in sensory function accompany many neuromuscular disorders. Assess sensory function in a similar fashion to that used in the adult. The sensory functions of light touch, pain, vibration, heat, and cold are distinguishable by a child. In the infant, assess for response to light touch or pain. The usual response to pain will be withdrawal from the stimulus. Always prepare the child for the sensory examination in order to gain cooperation. The pinprick test may be particularly frightening, but most children will cooperate if educated appropriately.

Palpation

Assess muscle strength and tone in the infant or child. Compare strength and tone bilaterally. Evaluate neck tone by pulling the infant from a supine position to a sitting position (Fig. 43.1). By 4 to 5 months the infant should be able to maintain the head in a neutral position. Perform passive range of motion of the neck. Alterations in range of motion may indicate a neuromuscular disorder or torticollis. Note trunk tone in the infant by holding the infant under the axillae and palpating for trunk tone. The hypotonic infant will feel as though he or she is slipping through the examiner's hands. The hypertonic infant will feel rigid, extending the trunk and legs. Assess leg tone in the infant by placing the infant in the vertical position with the feet on a flat surface; the 4-month-old infant should be able to momentarily support his or her weight. Assess the strength of the infant or child by noting ability to move the muscles

FIGURE 43.1 Assessing neck tone in an infant.

FIGURE 43.2 Assessing leg strength of the child.

against gravity (Fig. 43.2). Note any hypertonia or **spasticity**, which may be an early indication of cerebral palsy or other neuromuscular disorder.

▶ ***Take*** *NOTE!*

In cases of trauma or suspected trauma, do not perform any assessment that involves movement of the head and neck until cervical injury is ruled out. Maintain complete immobilization of the cervical spine until that time.

Auscultation

Auscultate the child's lungs; adventitious sounds are often present when respiratory muscle function is impaired.

Laboratory and Diagnostic Testing

Common Laboratory and Diagnostic Tests 43.1 offers an explanation of the laboratory and diagnostic tests most commonly used in neuromuscular disorders. The tests can assist the physician in diagnosing the disorder and/or be used as guidelines in determining ongoing treatment. Laboratory or non-nursing personnel perform some of

COMMON LABORATORY AND DIAGNOSTIC TESTS 43.1

Test	Explanation	Indication	Nursing Implications
Cervical spine x-rays	Radiographic image of the cervical spine	Detection of spinal fractures	In the trauma victim, the cervical spine should remain immobilized until cleared after cervical spine x-rays.
Fluoroscopy	Radiographic examination that uses continuous x-rays to show live, real-time images	Assessment of cervical spine instability during movement	Children may be afraid of the x-ray machine but will need to cooperate with flexion and extension of the neck. Allow a parent or family member to accompany the child.
Myelography	X-ray study of the spinal cord allowing visualization of the cord, nerve roots, and surrounding meninges	Detection of space-occupying lesions of the spinal cord; visualization of neural tube defects; evaluation of traumatic injury	Involves injection of contrast medium into the CSF via lumbar puncture. After procedure, keep head of bed elevated for several hours. Encourage hydration. Observe for signs of meningeal irritation.

(continued)

COMMON LABORATORY AND DIAGNOSTIC TESTS 43.1 (continued)

Test	Explanation	Indications	Nursing Implications
Ultrasound	Use of sound waves to locate the depth and structure within soft tissues and fluid	Assessment of spinal abnormalities	Better tolerated by nonsedated children than CT or MRI. Can be performed with a portable unit at bedside.
Computed tomography (CT)	Noninvasive x-ray study that looks at tissue density and structures. Images a "slice" of tissue.	Evaluation of congenital abnormalities such as neural tube defects, fractures, demyelinization, or inflammation	Machine is large and can be frightening to children. Procedure can be lengthy and child must remain still. If unable to do so, sedation may be necessary. If performed with contrast medium, assess for allergy. Encourage fluids after procedure if not contraindicated.
Magnetic resonance imaging (MRI)	Based on how hydrogen atoms behave in a magnetic field when disturbed by radiofrequency signals. Does not require ionizing radiation. Provides a 3D view of the body part being scanned.	Assessment of inflammation, congenital abnormalities such as neural tube defects	Remove all metal objects from the child. Child must remain motionless for entire scan; parent can stay in room with child. Younger children will require sedation in order to be still. A loud thumping sound occurs inside the machine during the procedure, which can be frightening to children.
Creatine kinase	Reflects muscle damage: it leaks from muscle into plasma as muscles deteriorate	Diagnosis of muscular dystrophy, spinal muscular atrophy	Draw sample before electromyogram or muscle biopsy, as those tests may lead to release of creatine kinase.
Electromyography	A recording electrode is placed in the skeletal muscle and electrical activity is recorded.	Differentiates muscular disorders from those that are neurologic in origin	Requires insertion of short needles into the muscles.
Nerve conduction velocity	Measures the speed of nerve conduction	Differentiation of muscular disorders	Feels like mild electric shocks
Muscle biopsy	Removal of a piece of muscular tissue either by needle or by open biopsy	Determination of type of muscular dystrophy or spinal muscular atrophy	Post-biopsy care is similar to that for other types of biopsy. Involves a small incision with one or two sutures.
Dystrophin	A normal intracellular plasma membrane protein in the muscle	Determination of specific type of muscular dystrophy	Absent in Duchenne muscular dystrophy, decreased in Becker muscular dystrophy
Genetic testing	Tests for presence of the gene for the disease or for carrier status	Determination of disease or carrier status of inherited muscular disorder	Entire family should be tested, even those unaffected, because carrier status should be determined and genetic counseling related to reproduction provided.

the tests, while the nurse might perform others. In either instance the nurse should be familiar with how the tests are performed, what they are used for, and normal versus abnormal results. This knowledge will also be necessary when providing patient and family education related to the testing.

Nursing Diagnoses, Goals, Interventions, and Evaluations

Upon completion of a thorough assessment, the nurse might identify several nursing diagnoses, including:

- Impaired physical mobility
- Imbalanced nutrition, less than body requirements
- Urinary retention
- Constipation
- Self-care deficit
- Risk for impaired skin integrity
- Chronic sorrow
- Risk for injury
- Deficient knowledge
- Family processes, interrupted

After completing an assessment of Fredrick, the nurse noted the following: he started walking at 2 years of age, he has difficulty jumping, his gait has a waddling appearance, and he does not rise from the floor in the usual fashion. Based on these assessment findings, what would your top three nursing diagnoses be for Fredrick?

Nursing goals, interventions, and evaluation for the child with neuromuscular dysfunction are based on the nursing diagnoses (see Nursing Care Plan Overview 43.1). The nursing care plan may be used as a guide in planning

(text continues on page 1428)

Nursing Care Plan 43.1

Overview for the Child with a Neuromuscular Disorder

NURSING DIAGNOSIS: Impaired physical mobility related to muscle weakness, hypertonicity, impaired coordination, loss of muscle function or control as evidenced by an inability to move extremities, to ambulate without assistance, to move without limitations

Outcome Identification and Evaluation

Child will be able to engage in activities within age parameters and limits of disease: *child is able to move extremities, move about environment, and participate in exercise programs within limits of age and disease.*

Intervention: Maximizing Physical Mobility

- Encourage gross and fine motor activities *to facilitate motor development.*
- Collaborate with physical therapy, occupational therapy, and speech therapy to strengthen muscles and promote optimal mobility *to facilitate motor development.*
- Use passive and active range-of-motion exercises and teach child and family how to perform them *to prevent contractures, facilitate joint mobility and muscle development (active ROM), and help increase mobility.*
- Praise accomplishments and emphasize child's abilities *to improve self-esteem and encourage feeling of confidence and competence.*

NURSING DIAGNOSIS: Nutrition, imbalanced, less than body requirements, related to difficulty feeding secondary to deficient sucking, swallowing, or chewing; difficulty assuming normal feeding position; inability to feed self as evidenced by decreased oral intake, impaired swallowing, weight loss or plateau.

Outcome Identification and Evaluation

Child will exhibit signs of adequate nutrition *as evidenced by appropriate weight gain, intake & output within normal limits, and adequate ingestion of calories.*

Intervention: Promoting Adequate Nutrition

- Monitor height and weight: *insufficient intake will lead to impaired growth and weight gain.*
- Monitor hydration status (moist mucous membranes, elastic skin turgor, adequate urine output): *insufficient intake can lead to dehydration.*

(continued)

Nursing Care Plan 43.1 (continued)

- Use techniques to promote caloric and nutritional intake and teach family about these techniques (e.g., positioning, modified utensils, soft or blended foods, allowing extra time) *to facilitate intake.*
- Assess respiratory system frequently *to assess for aspiration.*
- Assist family to help child assume as normal a feeding position as possible *to help increase oral intake.*

NURSING DIAGNOSIS: Urinary retention related to sensory motor impairment as evidenced by dribbling, inadequate bladder emptying

Outcome Identification and Evaluation

Child's bladder will empty adequately, *according to pre-established quantities and frequencies individualized for the child (usual urine output is 0.5 to 2 mL/kg/hour).*

Intervention: Promoting Successful Bladder Emptying

- Assess child's ability to empty bladder via history focused on character and duration of lower urinary symptoms *to establish baseline.*
- Assess for history of fecal impaction or constipation, *as alterations in bowel elimination may hinder urinary elimination.*
- Assess for bladder distention by palpation or urinary retention by post-void residual obtained via catheterization or bladder ultrasound *to determine extent of retention.*
- Maintain adequate hydration *to avoid irritating effects that dehydration has on the bladder.*
- Schedule voiding to *decrease bladder overdistention.*
- Teach the family (and the child if old enough) with significant urinary retention the technique of clean intermittent catheterization *to allow regular, complete bladder emptying.*

NURSING DIAGNOSIS: Risk for constipation related to immobility, loss of sensation

Outcome Identification and Evaluation

Child will demonstrate adequate stool passage, *will pass soft, formed stool every 1 to 3 days without straining or other adverse effects.*

Intervention: Promoting Appropriate Bowel Elimination

- Assess usual pattern of stooling *to determine baseline and identify potential problems with elimination.*
- Palpate for abdominal fullness and auscultate for bowel sounds *to assess for bowel function and presence of constipation.*
- Encourage fiber intake *to increase frequency of stools.*
- Ensure adequate fluid intake *to prevent formation of hard, dry stools.*
- Encourage activity within child's limits or restrictions: *even minimal activity increases peristalsis.*
- Administer medications or enemas as ordered *to promote bowel training/evacuation (especially in child with myelomeningocele or spinal cord injury).*

NURSING DIAGNOSIS: Self-care deficit related to neuromuscular impairments, cognitive deficits as evidenced by an inability to perform hygiene care and transfer self independently

Outcome Identification and Evaluation

Child will demonstrate ability to care for self within age parameters and limits of disease: *Child is able to feed, dress, manage elimination within limits of disease and age.*

Intervention: Maximizing Self-Care

- Introduce child and family to self-help methods as soon as possible *to promote independence from the beginning.*
- Encourage family and staff to allow child to do as much as possible *to allow child to gain confidence and independence.*
- Teach specific measures for bowel and urinary elimination as needed *to promote independence and increase self-care abilities and self-esteem.*
- Collaborate with physical therapy, occupational therapy, and speech therapy to provide child and family with appropriate tools to modify environment and methods to promote transferring and self-care *to allow for maximum functioning.*
- Praise accomplishments and emphasize child's abilities *to improve self-esteem and encourage feelings of confidence and competence.*
- Balance activity with periods of rest *to reduce fatigue and increase energy for self-care.*

Nursing Care Plan 43.1 (continued)

NURSING DIAGNOSIS: Risk for impaired skin integrity related to immobility, use of braces or adaptive devices

Outcome Identification and Evaluation

Child's skin will remain intact, *without evidence of redness or breakdown.*

Intervention: Promoting Skin Integrity

- Monitor condition of entire skin surface at least daily *to provide baseline and allow for early identification of areas at risk.*
- Avoid excessive friction or harsh cleaning products *that may increase risk of breakdown in child with susceptible skin.*
- Keep child's skin free from stool and urine *to decrease risk of breakdown.*
- Change child's position frequently *to decrease pressure to susceptible areas.*
- Monitor skin condition affected by braces or adaptive equipment frequently *to prevent skin breakdown related to poor fit.*

NURSING DIAGNOSIS: Chronic sorrow related to presence of chronic disability as evidenced by child's or family's expression of sadness, anger, disappointment, or feeling overwhelmed

Outcome Identification and Evaluation

Child and/or family will accept situation; *child/family will appropriately identify feelings, function at a normal developmental level, and plan for the future.*

Intervention: Easing Sorrow

- Assess degree of sorrow *to provide baseline for intervention.*
- Identify problems with eating or sleeping, *often affected when grief or sorrow is present.*
- Spend time with the child and family; *an empathetic presence is valued by suffering families.*
- Encourage the use of positive coping techniques; *taking action, expressing feelings, intentional attempts at coping are helpful techniques.*
- Refer for spiritual counseling as desired; *many families experience grief resolution in a more timely fashion if spiritual needs are addressed.*

NURSING DIAGNOSIS: Risk for injury related to muscle weakness

Outcome Identification and Evaluation

Child will remain free from injury; *child will not fall or experience other injury.*

Intervention: Preventing Injury

- Ensure that side rails of bed are elevated when caregiver is not directly at bedside *to prevent fall from bed.*
- Use appropriate safety restraints with adaptive equipment and wheelchairs *to prevent fall or slipping from equipment.*
- Do not leave child unattended in tub *as weakness may cause the child to slip under the water.*
- Avoid restraint use if at all possible; *close observation is more appropriate.*

NURSING DIAGNOSIS: Deficient knowledge related to lack of information regarding complex medical condition, prognosis, and medical needs as evidenced by verbalization, questions, or actions demonstrating lack of understanding regarding child's condition or care

Outcome Identification and Evaluation

Child and family will verbalize accurate information and understanding about condition, prognosis, and medical needs: *Child and family demonstrate knowledge of condition and prognosis and medical needs, including possible causes, contributing factors, and treatment measures.*

Intervention: Providing Patient and Family Teaching

- Assess child's and family's willingness to learn: *Child and family must be willing to learn for teaching to be effective.*
- Provide family with time to adjust to diagnosis *to facilitate adjustment and ability to learn and participate in child's care.*
- Repeat information *to allow family and child time to learn and understand.*
- Teach in short sessions: *many short sessions are more helpful than one long session.*

(continued)

Nursing Care Plan 43.1 (continued)

- Gear teaching to the level of understanding of the child and family (depends on age of child, physical condition, memory) *to ensure understanding.*
- Provide reinforcement and rewards *to facilitate the teaching/learning process.*
- Use multiple modes of learning involving many senses (provide written, verbal, demonstration and videos) when possible: *child and family are more likely to retain information when it is presented in different ways using many senses.*

NURSING DIAGNOSIS: Family processes, interrupted, related to child's illness, hospitalization, diagnosis of chronic illness in child, and potential long-term effects of illness as evidenced by family's presence in hospital, missed work, demonstration of inadequate coping

Outcome Identification and Evaluation

Family will maintain functional system of support, demonstrate adequate coping, adaptation of roles: *Parents are involved in child's care, ask appropriate questions, express fears and concerns, and are able to discuss child's care and condition calmly.*

Intervention: Promoting Appropriate Family Functioning

- Encourage parents and family to verbalize concerns related to child's illness, diagnosis, and prognosis: *allows the nurse to identify concerns and areas where further education may be needed; demonstrates family-centered care.*
- Explain therapies, procedures, child's behaviors, and plan of care to parents: *understanding of the child's current status and plan of care helps decrease anxiety.*
- Encourage parental involvement in care *to allow parents to feel needed and valued and to have a sense of control over their child's health.*
- Identify support system for family and child: *support system is often needed by stressed families to assist with coping.*
- Educate family and child on additional resources available *to help them develop a wide base of support.*

nursing care for the child with a neuromuscular disorder. The care plan includes many nursing diagnoses that are applicable to the child or adolescent. Children's responses to neuromuscular dysfunction and its treatment will vary, and nursing care should be individualized based on the child's and family's responses to illness; see Healthy People 2010. Additional information about nursing management will be included later in the chapter as it relates to specific disorders.

HEALTHY PEOPLE 2010

Objective	Significance
Increase the proportion of children with special health needs who have access to a medical home.	• Educate the family that specialist care (though often consisting of frequent and multiple visits) does not replace primary care through the medical home. • Encourage families to find a primary care pediatrician with whom they feel comfortable for well-child check-ups and routine childhood illnesses.

Based on your top three nursing diagnoses for Fredrick, describe appropriate nursing interventions.

Congenital Neuromuscular Disorders

Several disorders with neuromuscular effects are congenital in nature. These include the neural tube defects and genetic neuromuscular disorders. The structural disorders are spina bifida occulta, meningocele, and myelomeningocele (neural tube defects). The genetic neuromuscular disorders include the various types of muscular dystrophy and

spinal muscular atrophy. These disorders are not always recognized at birth, as signs and symptoms are not evident until months or even years after birth, but they are still considered to be congenital as they have a genetic basis.

NEURAL TUBE DEFECTS

Neural tube defects account for the majority of congenital anomalies of the central nervous system. The neural tube closes between the third and fourth week of gestation. The cause of neural tube defects is not known, but many factors, such as drugs, malnutrition, chemicals, and genetics, can hinder normal central nervous system development. Strong evidence exists that supplementation of folic acid by the mother before conception decreases the incidence of neural tube defects in pregnancies at risk by 50% (Kliegman et al., 2007). In 1992 the U.S. Public Health Service recommended that all women of childbearing age who are capable of becoming pregnant take 0.4 mg of folic acid daily (CDC, 2007). According to the Centers for Disease Control and Prevention (CDC), the number of pregnancies affected by neural tube defects decreased from 4,000 in 1995–1996 to 3,000 in 1999–2000 (Merereau et al., 2004). Prenatal screening of maternal serum for alpha-fetoprotein (AFP) and ultrasound at 16 to 18 weeks of gestation can help identify fetuses at risk. Neural tube defects primarily affecting spinal cord development include spina bifida occulta, meningocele, and myelomeningocele (Fig. 23.3). Neural tube defects primarily affecting brain development are discussed in Chapter 38.

Spina Bifida Occulta

Spina bifida is a term that is often used to refer to all neural tube disorders that affect the spinal cord. This can be confusing and a cause of concern for parents. There are well-defined degrees of spinal cord involvement, and use of the correct terminology is important for health care professionals.

Spina bifida occulta is a defect of the vertebral bodies without protrusion of the spinal cord or meninges. This defect is not visible externally and in most cases has no adverse affects (see Fig. 43.3). Spina bifida occulta is a common anomaly: it is estimated that it affects one fifth of the population (Spina Bifida Association, 2006). Children with spina bifida occulta need no immediate medical intervention. Complications may include tethered cord, syringomyelia, or diastematomyelia.

Nursing Assessment

In most cases, spina bifida occulta is benign and asymptomatic and produces no neurologic signs; it may be considered a normal variant. The defect, which is usually present in the lumbosacral area, often goes undetected. However, there may be noticeable dimpling, abnormal patches of hair, or discoloration of skin at the defect site. If so, further investigation, including magnetic resonance imaging (MRI), may be warranted.

Nursing Management

Nursing care will focus on educating the family. Inform parents of its presence and what the diagnosis means. Many times parents will confuse this diagnosis with spina bifida cystica, a much more serious defect. Occasionally, children with spina bifida occulta eventually need surgical intervention due to degenerative changes or involvement of the spine and nerve roots resulting in complications such as tethered cord, syringomyelia, or diastematomyelia. When these associated problems occur, the condition is often termed "occult spinal dysraphism" to avoid confusion.

Meningocele

Meningocele, the less serious form of spina bifida cystica, occurs when the meninges herniate through a defect in

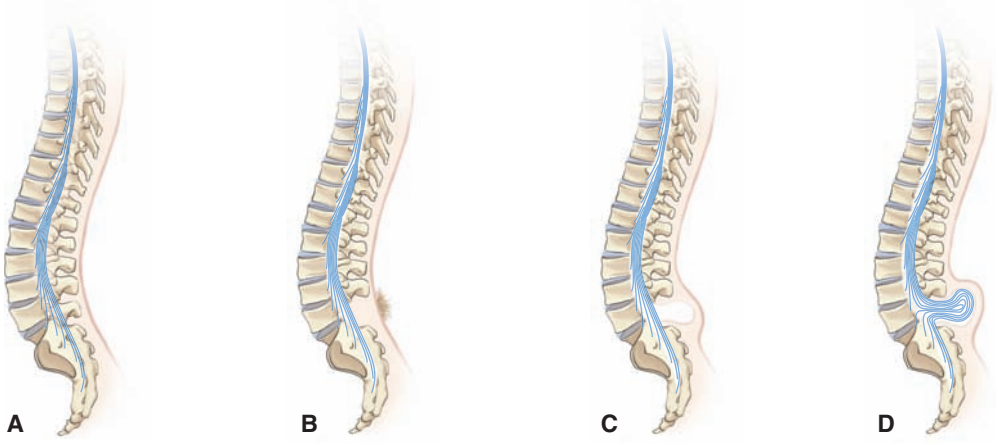

FIGURE 43.3 (**A**) Normal spine. (**B**) Spina bifida occulta. (**C**) Meningocele. (**D**) Myelomeningocele

the vertebrae. The spinal cord is usually normal and there are typically no associated neurologic deficits. Treatment for meningocele involves surgical correction of the lesion (see Fig. 43.3).

Nursing Assessment

Initial assessment after delivery will reveal a visible external sac protruding from the spinal area. It is most often seen in the lumbar region but can be anywhere along the spinal canal. Most are covered with skin and pose no threat to the patient. However, assessment to ensure that the sac covering is intact remains important. Assess neurologic status carefully: most children will be asymptomatic, with no neurologic deficits. Before surgical correction the infant will be thoroughly examined to determine whether there is any neural involvement or associated anomalies. Diagnostic procedures such as computed tomography (CT), MRI, and ultrasound may be performed.

Nursing Management

If the skin covering the sac is intact, surgical correction may be delayed. However, as in a child with myelomeningocele, immediately report any evidence of leaking cerebrospinal fluid (CSF) to ensure prompt intervention to prevent infection. Nursing management will be supportive. Provide preoperative and postoperative care similar to the child with myelomeningocele to prevent rupture of the sac, to prevent infection, and to provide adequate nutrition and hydration. Monitor for symptoms of constipation or bladder dysfunction that may result due to increasing size of the lesion. Resulting hydrocephalus has been associated with some cases of meningocele; therefore, monitor head circumference and watch for signs and symptoms of increased intracranial pressure (ICP).

Myelomeningocele

Myelomeningocele, the most severe form of neural tube defect, occurs in approximately 1 in 4,000 live births (Kliegman et al., 2007). Myelomeningocele is a type of spina bifida cystica, and clinically the term "spina bifida" is often used to refer to myelomeningocele. It may be diagnosed *in utero* via ultrasound; otherwise it is visually obvious at birth. The newborn with myelomeningocele is at increased risk for meningitis, hypoxia, and hemorrhage.

In myelomeningocele, the spinal cord often ends at the point of the defect, resulting in absent motor and sensory function beyond that point (see Fig. 43.3). Therefore, the long-term complications of paralysis, orthopedic deformities, and bladder and bowel incontinence are often seen in children with myelomeningocele. The presence of **neurogenic** bladder and frequent catheterization puts the child at an increased risk for urinary tract infections, pyelonephritis, and hydronephrosis, which may result in long-term renal damage if managed inappropriately. Accompanying hydrocephalus associated with type II Chiari defect is seen in 80% of patients with myelomeningocele (Kliegman et al., 2007). Due to the improper development and the downward displacement of the brain into the cervical spine, CSF flow is blocked, resulting in hydrocephalus. The lower the deformity is on the spine, the lower the risk of developing hydrocephalus.

These children usually require multiple surgical procedures and due to frequent catheterizations are at an increased risk of developing a latex allergy. Learning problems and seizures are more common in these children than in the general population, but 70% of those with myelomeningocele have normal intelligence (Kliegman et al., 2007). Ambulation is possible for some children, depending on the level of the lesion. Due to advances in medical treatment the life expectancy of children with this disorder has increased. For children born with a myelomeningocele who receive aggressive treatment, the mortality rate is 10% to 15%; most deaths occur before the age of 4 years old (Kliegman et al., 2007).

Pathophysiology

The cause of myelomeningocele is unknown, but risk factors are consistent with other neural tube defects, such as maternal drug use, malnutrition, and a genetic predisposition. In myelomeningocele, the neural tube fails to close at the end of the fourth week of gestation. As a result, an external sac-like protrusion that encases the meninges, spinal fluid, and in some cases nerves is present on the spine (see Fig. 43.3). A myelomeningocele can be located anywhere along the spinal cord, but 75% are located in the lumbosacral region (Kliegman et al., 2007). The degree of neurologic deficit will depend on the location. An increase in neurologic deficit is seen as the myelomeningocele extends into the thoracic region.

Therapeutic Management

Surgical closure will be performed as soon as possible after birth, especially if a CSF leak is present or if there is a danger of the sac rupturing. The goal of early surgical intervention is to prevent infection and to minimize further loss of function, which can result from the stretching of nerve roots as the meningeal sac expands after birth. A new option is becoming available but remains experimental. *In utero* fetal surgery to repair the myelomeningocele has been performed in the United States. The benefits and risks remain uncertain at this time. Ongoing management of this disorder remains complex; a multidisciplinary approach is needed, involving specialists in neurology, neurosurgery, urology, orthopedics, therapy, and rehabilitation along with intense nursing care. The chronic nature of this disorder necessitates lifelong follow-up.

Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1420. Assessment findings pertinent to myelomeningocele are discussed below.

Health History

High-risk deliveries should be identified. Explore the pregnancy history and past medical history for risk factors such as:

- Lack of prenatal care
- Lack of preconception and/or prenatal folic acid supplementation
- Previous child born with neural tube defect or family history of neural tube defects
- Maternal consumption of certain drugs that antagonize folic acid, such as anticonvulsants (carbamazepine and phenobarbital)

The older infant or child with a history of myelomeningocele requires numerous surgical procedures and lifelong follow-up. In an infant or child returning for a clinic visit or hospitalization, the health history should include questions related to:

- Current mobility status and any changes in motor abilities
- Genitourinary function and regimen
- Bowel function and regimen
- Signs or symptoms of urinary infections
- History of hydrocephalus with presence of shunt
- Signs or symptoms of shunt infection or malfunction (refer to section on hydrocephalus)
- Latex sensitivity
- Nutritional status, including changes in weight
- Any other changes in physical or cognitive state
- Resources available and used by the family

Physical Examination

Initial assessment after delivery will reveal a visible external sac protruding from the spinal area (Fig. 43.4). Observe the baby's general appearance and assess whether the sac covering is intact. Assess neurologic status and look for associated anomalies. Assess for movement of extremities and anal reflex, which will help determine the level of neurologic involvement. Flaccid paralysis, absence of deep tendon reflexes, lack of response to touch and pain stimuli, skeletal abnormalities such as club feet, constant dribbling of urine, and a relaxed anal sphincter may be found.

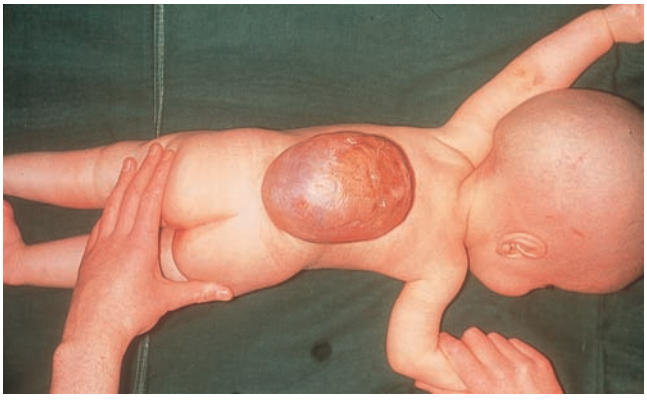

FIGURE 43.4 Usually a sac covers the deformity of myelomeningocele and is visible at birth.

In the older infant or child, perform a thorough physical examination and focus on the functional assessment. Note level of paralysis or paresthesia. Inspect skin for breakdown. Determine the child's motor capabilities.

Laboratory and Diagnostic Tests

A myelomeningocele may be detected prenatally around 16 to 18 of weeks' gestation by ultrasound, by a blood test that detects AFP increases, or by analysis of amniotic fluid for AFP increases. Common laboratory and diagnostic studies ordered for the assessment of myelomeningocele include:

- MRI
- CT
- Ultrasound
- Myelography

These diagnostic tests are used to evaluate brain and spinal cord involvement (refer to Common Laboratory and Diagnostic Tests 43.1).

Nursing Management

Initial nursing management of the child with myelomeningocele involves preventing trauma to the meningeal sac and preventing infection before surgical repair of the defect. Refer to the Nursing Care Plan Overview in this chapter. Additional considerations are reviewed below.

Preventing Infection

Risk for infection related to the presence of the meningeal sac and potential for rupture is a central nursing concern in the newborn with myelomeningocele. Until surgical intervention occurs, the goal is to prevent rupture or leakage of CSF from the sac. Keeping the sac from drying out is important, as well as preventing trauma or pressure on the sac. Use sterile saline-soaked non-adhesive gauze or antibiotic-soaked gauze to keep the sac moist. Immediately report any seepage of clear fluid from the lesion, as this could indicate an opening in the sac and provide a portal of entry for microorganisms. Position the infant in the prone position or supported on the side to avoid pressure on the sac. To keep the infant warm, place the infant in a warmer or Isolette to avoid the use of blankets, which could exert too much pressure on the sac. Pay special attention while the infant is in a warmer or Isolette because the radiant heat can cause drying and cracking of the sac.

Keep the lesion free of feces and urine to help avoid infection. Position the infant so that urine and feces flow away from the sac (e.g., prone position, or place a folded towel under the abdomen) to help prevent infection. Placing a piece of plastic wrap below the meningocele is another way of preventing feces from coming into contact with the

lesion. After surgery, position the infant in the prone or side-lying position to allow the incision to heal. Continue with precautions to prevent urine or feces from coming into contact with the incision.

Promoting Urinary Elimination

Children with myelomeningocele often have bladder incontinence, though some children may achieve normal urinary continence. The level of the lesion will influence the amount of dysfunction. Myelomeningocele remains one of the most common causes of neurogenic bladder in children. Therefore, evaluation of renal function by a pediatric urologist should be performed on each child with myelomeningocele.

Neurogenic bladder refers to the failure of the bladder to either store urine or empty itself of urine. Children with neurogenic bladder have loss of control over voiding. The spastic type of neurogenic bladder is hyperreflexive and yields frequent release of urine, but with incomplete emptying. The hypotonic neurogenic bladder is flaccid and weak and becomes stretched out; it can hold very large amounts of urine, resulting in continuous dribbling of urine from the urethra. Urinary stasis and retention occur in both types, placing the child at risk for urinary tract infection as well as reflux of bladder contents back up into the ureters and kidneys, resulting in renal scarring and insufficiency.

The goals of neurogenic bladder management are to promote optimal urinary continence and prevent renal complications. Interventions for neurogenic bladder include clean intermittent catheterization to promote bladder emptying; medications such as oxybutynin chloride (Ditropan) to improve bladder capacity; prompt recognition and treatment of infections; and in some children surgical interventions such as a continent urinary reservoir or vesicostomy to facilitate urinary elimination. Clean intermittent catheterization is addressed below. In the child with a spastic or rigid bladder, teach parents how to administer antispasmodic medications such as oxybutynin. Teach the parents that the medication is used to increase the bladder capacity and reduce the potential for reflux. Refer to Chapter 42 for additional information on nursing care related to the surgical procedures.

Assessing Urinary Function

Determine the child's pattern and success of toilet training, both for bladder and bowel. Assess the child's cognitive/developmental level. Observe the genital area for dribbling of urine from the urethra, noting odor of urine if present. Note redness of the urethra or excoriation in the diaper area. Inspect the abdomen for scars from prior surgeries and the presence of urinary diversion or continent stoma. Palpate the abdomen for presence of distended bladder, fecal mass, or enlarged kidneys. Determine the child's level of paralysis or paresthesia.

Clean Intermittent Catheterization

Depending on the level of paralysis at birth in the child with myelomeningocele, clean intermittent catheterization may be started at that time. In other children with spina bifida and in children who suffer spinal cord injury, catheterization may be started at a later age. Teach parents the technique of clean intermittent catheterization via the urethra, unless a urinary diversion or continent stoma has been created (Teaching Guidelines 43.1).

Teaching the parents the techniques of clean intermittent catheterization is an important step in preserving renal functioning, preventing infection and helping the family gain some control over the child's physical condition. Until

EVIDENCE-BASED PRACTICE 43.1

Self-Intermittent Catheterization Among Female Children With Myelomeningocele and the Potential for Increased Complications

● Study

The authors reviewed the medical records of 31 females with myelomeningocele followed from the start of clean intermittent catheterization (CIC). Between all subjects, CIC was used for 459 patient-years. In all cases, the girls used noncoated polyvinyl chloride catheters.

▲ Findings

Over the total 459 patient-years, 13 patients experienced a total of 20 episodes of complications among them. These included hematuria, urethral polyps, and difficulties in catheterization. Complications were increased if assisted CIC was used or if a smaller bore catheter was utilized.

■ Nursing Implications

There are few complications occurring in females with myelomeningocele who self-catheterize using clean technique. Encourage the use of large-size noncoated polyvinyl catheters. Teach females when developmentally capable to perform self CIC. This function is safe and yields greater independence in this special population.

Source: Lindehall, B., Abrahamsson, K., Jodal, U., Olsson, I., & Sillen, U. (2007). Complications of clean intermittent catheterization in young females with myelomeningocele: 10 to 19 years of followup. *Journal of Urology, 178*(3), 1053–1055.

TEACHING GUIDELINES 43.1

Clean Intermittent Catheterization

- Wash hands with soap and water.
- Apply water-based lubricant to catheter.
- Perform catheterization. Insert catheter only as far as needed to obtain urine flow.
- Wash reusable catheter after use with soapy water; rinse and allow to dry.
- When dry, store in zip-top plastic bag or other clean storage container.
- Weekly, soak the catheter in a 1:1 vinegar and water solution, rinsing well before next use.
- When developmentally ready, teach the child to self-catheterize.

the child is able to self-catheterize, the parents will be responsible for this procedure. Children with normal intelligence and upper extremity motor skills usually learn to self-catheterize at the age of 6 years. Urinary incontinence is associated with poor self-esteem, particularly as the child gets older. Educating the child to self-catheterize the urethra or stoma as appropriate empowers the child, gives him or her a sense of control, and allows for appropriate urinary elimination when the child is away from the parents (e.g., at school).

Offer support and appropriate referrals to the child and family. Refer families to vendors in the local area for catheterization supplies.

▶ *Take* NOTE!

Over time, bacterial colonization of the bladder may occur; however, antibiotic prophylaxis is not recommended for these children because of the increased risk for development of antibiotic resistance.

Promoting Bowel Elimination

Children with myelomeningocele often have bowel incontinence as well; the level of the lesion affects the amount of dysfunction. Many children with myelomeningocele can achieve some degree of bowel continence. Bowel training with the use of timed enemas or suppositories along with diet modifications can allow for defecation at predetermined times once or twice a day. Although bowel incontinence can be difficult for children as they grow older due to social concerns and self-esteem and body image disturbances, it does not pose the same health risks as urinary incontinence.

▶ *Take* NOTE!

Use only latex-free catheters and gloves for catheterization of children with myelomeningocele and/or neurogenic bladder, as these children exhibit a high incidence of latex allergy.

Promoting Adequate Nutrition

The risk for altered nutrition, less than body requirements, related to the restrictions on positioning of the infant before and after surgery is another nursing concern. Assist the family in assuming as normal a feeding position as possible. Preoperatively, the risk of rupture may be too high to warrant holding. Therefore, the infant's head can be turned to the side or the infant can be placed in the side-lying position to facilitate feeding. If the infant is held, special care needs to be taken to avoid pressure on the sac or postoperative incision. Encourage the parents to interact as much as possible with the infant by talking to and touching the infant during feeding to help promote intake. If the mother was planning on breastfeeding the infant, assist her in meeting this goal, if possible. If the infant can be held, encourage her to do this, or assist her in pumping and saving breast milk to be given to the infant via bottle until the infant is able to be held. Feeding an infant in an unusual position can be difficult, and it is the nurse's role to provide support, education, and modeling for the parents and family when needed.

Preventing Latex Allergic Reaction

Sensitivity to latex or natural rubber is very common among children with myelomeningocele. They are at an increased risk of developing an allergy to latex related to the multiple exposures to latex products during surgical procedures and bladder catheterizations. Research has shown that at least 70% of children who require repeat surgeries due to spina bifida are sensitive to latex (Noble, 2005). A latex-free environment should be created for all procedures performed on children with myelomeningocele to prevent latex allergy. Therefore, children at high risk for or with a known latex allergy must be identified and managed in a latex-free environment. Ensure that these children do not come into direct contact with latex or equipment and supplies that contain latex. Be familiar with those products and equipment at your facility that contain latex and those that are latex-free. The Food and Drug Administration now requires that all medical supplies be labeled if they contain latex, but this is not the case for consumer products. Many resources exist that list products that are latex-free, and each hospital should have such a list readily available to health care professionals. For an updated list of latex-containing products and other helpful information for parents regarding consumer products, contact the Spina Bifida Association

of America (www.sbaa.org; 4590 MacArthur Blvd. NW, Suite 250, Washington D.C. 20007; 1-800-621-3141 or 202-944-3295).

Children who are at a high risk for latex sensitivity should wear medical alert identification. Education programs regarding latex sensitivity and ways to prevent it need to be directed at those who care for high-risk children, including teachers, school nurses, relatives, babysitters, and all health care professionals.

Maintaining Skin Integrity

Address the risk for altered skin integrity related to the infant's prone position and impaired mobility. The prone position puts constant pressure on the knees and elbows, and it may be difficult to keep the infant clean of urine and feces. Diapering may be contraindicated preoperatively to avoid pressure on the sac. Therefore, ensure that the infant is kept as clean and dry as possible. This is made more difficult by the constant dribbling of stool and urine that may be present. Placing a pad beneath the diaper area and changing it frequently is important. Perform meticulous skin care. Place the infant on a special care mattress and place synthetic sheepskin under the infant to help reduce friction. Special attention to the infant's legs needs to occur when positioning them, since paralysis may be present. Using a folded diaper between the legs can help reduce pressure and friction from the legs rubbing together.

Educating and Supporting the Child and Family

Myelomeningocele is a serious disorder that affects multiple body systems and produces varying degrees of deficits. It is a disorder that has lifelong effects. Thanks to medical advances and technology most children born with myelomeningocele can expect to live a normal life, but challenges remain for the family and child as they learn to cope and live with this physical condition. Adjusting to the demands this condition places on the child and family is difficult. Parents may need time to accept their infant's condition, but as soon as possible they should be involved in the infant's care.

Teaching should begin immediately in the hospital. Teaching should include positioning, preventing infection, feeding, promoting urinary elimination through clean intermittent catheterization, preventing latex allergy, and the signs and symptoms of complications like increased ICP. Due to the chronic nature of this condition, long-term planning needs to begin in the hospital. These children usually require multiple surgical procedures and hospitalizations, and this can place stress on the family and their finances. The nurse has an important role in providing ongoing education about the illness and its treatments and the plan of care. As the family becomes more comfortable with the condition, they will become the experts in the child's care. Respect and recognize the family's changing needs. Providing intense daily care can take its toll on a family, and continual support and encouragement are needed. Referral to the Spina Bifida Association and a local support group for families of children with myelomeningocele is appropriate. See Healthy People 2010.

▶ *Consider THIS!*

A newborn has an obvious defect on his spine. Upon assessment, the nurse notes flaccid extremities and a distended bladder. The parents are devastated.

Identify additional assessments the nurse should make.

Describe nursing care for this neonate.

What teaching will the nurse do with this infant's family?

MUSCULAR DYSTROPHY

Muscular **dystrophy** refers to a group of inherited conditions that result in progressive muscle weakness and wasting. The muscles affected are primarily the skeletal (voluntary) muscles. Nine types of muscular dystrophy exist. All include muscle weakness over the lifetime; it is progressive in all cases but more severe in others. The various muscular dystrophies are most often diagnosed in childhood and affect a variety of muscle groups. The inheritance pattern for muscular dystrophy differs for each type but may be X-linked, autosomal dominant, or recessive. The genetic mutation in muscular dystrophy results in absence or decrease of a specific muscle protein that prevents normal function of the muscle. The skeletal muscle fibers are affected, yet there are no structural abnormalities in the spinal cord or the peripheral nerves. Table 43.1 gives specifics related to the various types of muscular dystrophy.

Duchenne muscular dystrophy, the most common neuromuscular disorder of childhood, is universally fatal (usually by the teens or twenties). The incidence is about 1 in 3,500 live male births (Balaban et al., 2005). For these reasons, this discussion will focus on Duchenne muscular dystrophy.

HEALTHY PEOPLE 2010

Objective	Significance
Increase the proportion of children and youth with disabilities who spend at least 80% of their time in regular education programs.	• Become familiar with local schools' offerings and capabilities so that you can refer families to an educational site appropriate for their child.

TABLE 43.1 TYPES OF MUSCULAR DYSTROPHY

Type	Onset	Inheritance	Muscle Involvement
Duchenne (pseudohypertrophic)	Early childhood	X-linked recessive	Generalized weakness, muscle wasting (limb and trunk first)
Becker	Adolescence or adulthood	X-linked recessive	Similar but less severe than Duchenne
Congenital	At birth	Autosomal dominant or recessive	Generalized muscular weakness, possible joint deformities
Emery-Dreifuss	Childhood to early teens	X-linked recessive	Weakness, wasting of shoulder, upper arm, and shin muscles
Limb-girdle	Childhood to middle age	Autosomal or X-linked recessive	Weakness, wasting of shoulder and pelvic girdles first
Facioscapulohumeral	Childhood to early adulthood	Autosomal dominant	Facial muscles weaken first, then shoulders and upper arms
Myotonic	Childhood to middle age	Autosomal dominant	Generalized weakness, wasting of face, feet, hands, and neck first Delayed relaxation of muscles after contraction
Oculopharyngeal	Early adulthood to middle age	Autosomal dominant	Affects muscles of eyelid and throat first
Distal	40 to 60 years of age	Autosomal dominant	Weakness, wasting of hand, forearm, lower leg muscles

Data from www.mda.org

Pathophysiology

The gene mutation in Duchenne muscular dystrophy results in the absence of dystrophin, a protein that is critical for maintenance of muscle cells. The gene is X-linked recessive, meaning that mainly boys are affected and they receive the gene from their mothers (women are carriers but have no symptoms). Absence of dystrophin leads to generalized weakness of voluntary muscles, and the weakness progresses over time. The hips, thighs, pelvis, and shoulders are affected initially; as the disease progresses, all voluntary muscles as well as cardiac and respiratory muscles are affected. Rarely, males with Duchenne muscular dystrophy may survive beyond the early 30s (Muscular Dystrophy Association, 2006b).

Boys with Duchenne muscular dystrophy are often late in learning to walk. As toddlers, they may display pseudohypertrophy (enlarged appearance) of the calves. During the preschool years they fall often and are quite clumsy. The affected child has difficulty climbing stairs and running and cannot get up from the floor in the usual fashion. The school-age child walks on the toes or balls of the feet with a rolling or waddling gait. Balance is disturbed significantly, and the child's belly may stick out when the shoulders are pulled back to stay upright and keep from falling over. During the school-age years it also becomes difficult for the child to raise his or her arms. Sometime between the ages of 7 and 12 years nearly all boys with Duchenne muscular dystrophy lose the ability to ambulate, and by the teen years any activity of the arms, legs, or trunk requires assistance or support. Most boys with Duchenne muscular dystrophy have normal intelligence, but many may exhibit a specific learning disability (Cotton et al., 2005).

Therapeutic Management

Though there is no cure for Duchenne muscular dystrophy, the use of corticosteroids may slow the progression of the disease. It is thought that prednisone helps by protecting muscle fibers from damage to the sarcolemma (defective in the absence of dystrophin). Numerous studies have shown that boys treated with prednisone demonstrate improved strength and function. The side effects of corticosteroids are many, including weight gain, osteoporosis, and mood changes (Palmieria & Sblendorio, 2007). Calcium supplements are prescribed to prevent osteoporosis, and antidepressants may be helpful when depression occurs related to the chronicity of the disease and/or as an effect of corticosteroid use; see Healthy People 2010. Braces or orthoses and mobility and positioning aids are necessary.

As the muscles deteriorate, joints may become fixated, resulting in **contractures**. Contractures restrict flexibility and mobility and cause discomfort. Sometimes contractures require surgical tendon release. Spinal curvatures

HEALTHY PEOPLE 2010

Objective	Significance
Reduce the proportion of children and adolescents with disabilities who are reported to be sad, unhappy, or depressed.	• Use every encounter with the child or adolescent with a disability as an opportunity to screen for mental health concerns. • Refer these children and teens as appropriate for mental health assessment and intervention.

result over time. The boy with Duchenne muscular dystrophy who can still walk may develop lordosis. More frequently, scoliosis or kyphosis develops with this disorder. Surgical spinal fixation with rod implantation is often required by the age of 11 to 13 years. Additional complications include pulmonary, urinary, or systemic infections, depression, learning or behavioral disorders, aspiration pneumonia (as oropharyngeal muscles become affected), cardiac dysrhythmias, and eventually respiratory insufficiency and failure (as weakness of the chest muscles and diaphragm progresses).

Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1420. Assessment findings pertinent to Duchenne muscular dystrophy are discussed below.

Health History

Examine the health history for a family history of neuromuscular disorders. Note pregnancy and delivery history, as this information may be useful in ruling out a pregnancy problem or birth trauma as a cause for the motor dysfunction. Determine status of developmental milestone achievement. Boys with Duchenne muscular dystrophy learn to walk but over time become unable to do so. If the child was previously diagnosed with muscular dystrophy, determine progression of disease. Inquire about functional status and need for assistive or adaptive equipment such as braces or wheelchairs. Determine skills related to activities of daily living. Note history of cough or frequent respiratory infections, which occur as the respiratory muscles weaken. While talking with the child and family, determine whether psychosocial issues such as decreased self-esteem, depression, alterations in socialization, or altered family processes might be present.

Physical Examination

Perform a thorough physical examination on the child with suspected muscular dystrophy or the child with known history of the disorder. Particular findings related to inspection, observation, auscultation, and palpation are presented below.

Inspection and Observation

Observe the child's ability to rise from the floor. A hallmark finding of Duchenne muscular dystrophy is the presence of Gowers' sign: the child cannot rise from the floor in standard fashion because of increasing weakness (Fig. 43.5). Observe the child's gait. Determine effectiveness of cough.

Auscultation and Palpation

Auscultate the heart and lungs. Note tachycardia, which develops as the heart muscle weakens. Note adequacy of breath sounds, which may diminish with decreasing respiratory function. Note muscle strength with resistance testing. Palpate muscle tone.

Laboratory and Diagnostic Tests

Electromyography (EMG) demonstrates that the problem lies in the muscles, not in the nerves. Serum creatine kinase levels are elevated early in the disorder, when significant muscle wasting is actively occurring. Muscle biopsy provides definitive diagnosis, demonstrating the absence of dystrophin. DNA testing reveals the presence of the gene.

Nursing Management

Nursing management is aimed at promoting mobility, maintaining cardiopulmonary function, preventing complications, and maximizing quality of life. Interventions directed at maintaining mobility and cardiopulmonary function also help to prevent complications. Refer to Nursing Care Plan Overview 43.1, and individualize nursing care based upon the child's and family's response to the illness. Additional specifics related to care of the child with muscular dystrophy are discussed below.

Promoting Mobility

Administer corticosteroids and calcium supplements as ordered. Encourage at least minimal weight-bearing in a standing position to promote improved circulation, healthier bones, and a straight spine. Boys with Duchenne muscular dystrophy may use a standing walker or standing frame to maintain an upright position. Perform passive stretching or strengthening exercises as recommended by the physical therapist. These exercises preserve mobility and may help to prevent muscle atrophy. Use orthotic supports such as hand braces or ankle–foot orthoses (AFOs) to prevent contractures of joints. Schedule activities during the part of the day when the child has the most energy. Teach parents the use of positioning, exercises, orthoses, and adaptive equipment.

Maintaining Cardiopulmonary Function

Assess respiratory rate, depth of respirations, and work of breathing. Auscultate the lungs to determine whether aeration is sufficient and to assess clarity of breath sounds. Position the child for maximum chest expansion, usually in

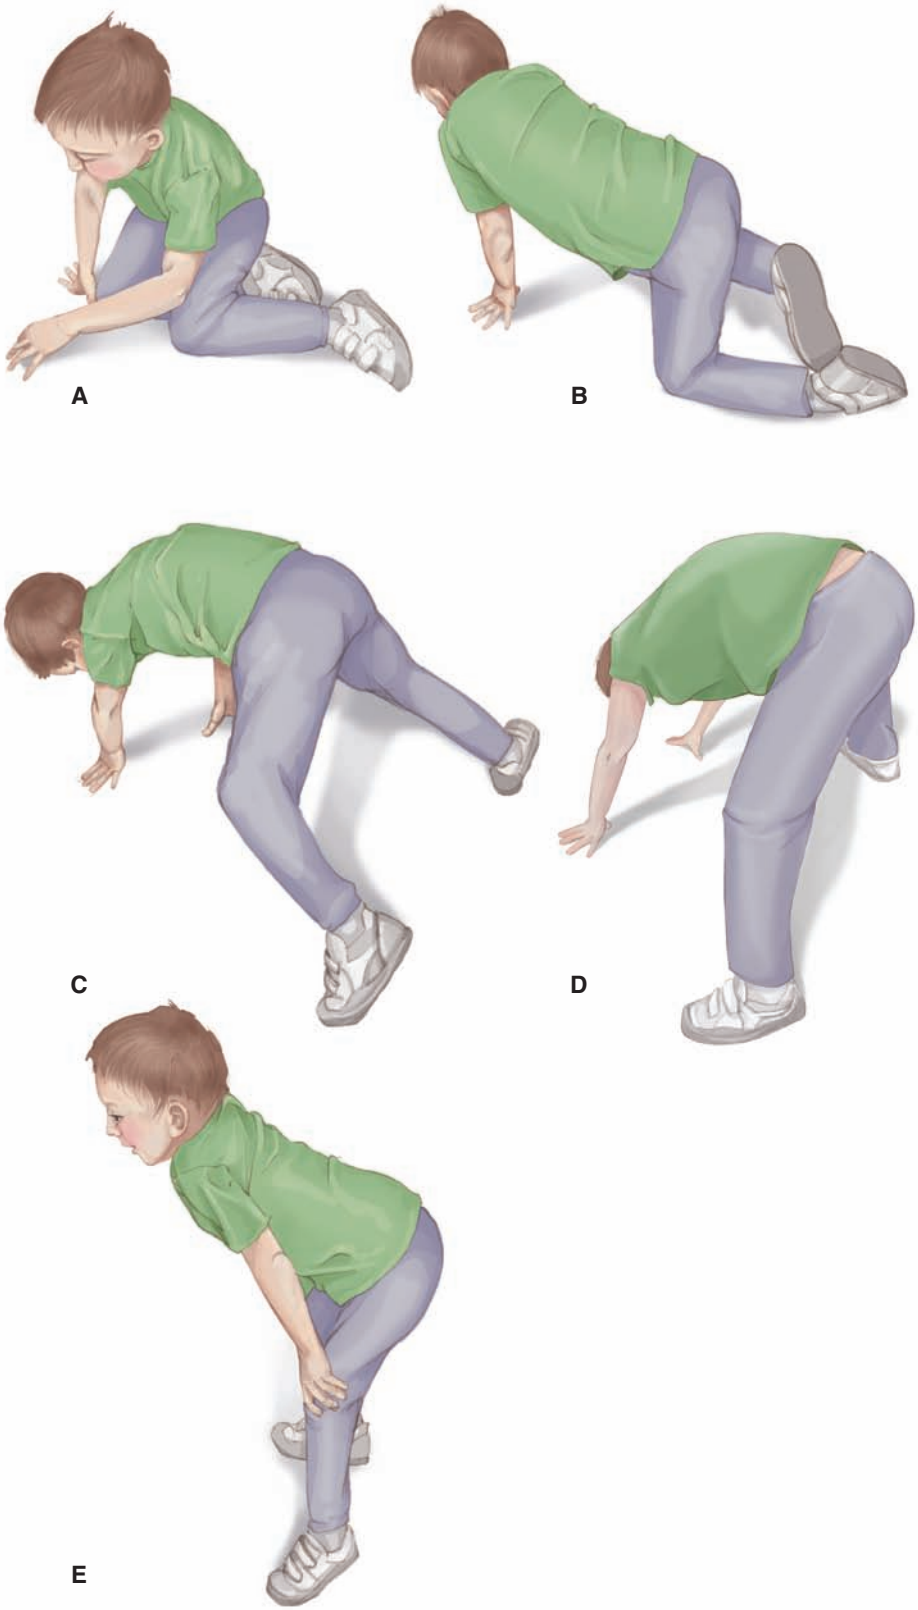

FIGURE 43.5 Gower's sign; (**A**) First the child must roll onto his hands and knees. (**B**) Then he must bear weight by using his hands to support some of his weight, while raising his posterior. (**C–E**) The boy then uses his hands to "walk" up his legs to assume an upright position.

the upright position. Teach the child and family deep-breathing exercises to strengthen or maintain respiratory muscles and encourage coughing to clear the airways. Perform chest physical therapy or assist with chest percussion. Monitor the results of pulmonary function testing. Use of intermittent positive-pressure ventilation and mechanically assisted coughing will become necessary in the teen years for some boys, possibly later for others. Teach parents monitoring and use of these modalities in conjunction with the respiratory therapist. Monitor cardiac status closely to identify heart failure early. Assess for edema, weight gain, or crackles. Strictly monitor fluid intake and output.

Maximizing Quality of Life

Long periods of bed rest may contribute to further weakness. Work with the family and child to develop a schedule for diversional activities that provide appropriate developmental stimulation but avoid overexertion or frustration (related to inability to perform the activity). Periods of adequate rest must be balanced with activities. Walking or riding a stationary bike is appropriate for the child who has upper extremity involvement. For the child with lower extremity involvement, a wheelchair may become necessary for mobility, and the child may participate in crafts, drawing, and computer activities. Participating in the Special Olympics may be appropriate for some children (www.specialolympics.org).

Provide emotional support to the child and family. Long-term direct care is stressful for families and becomes more complex as the child gets older. Families often need respite from continual caregiving duties. When a child is hospitalized, the caregiver may feel comfortable allowing nurses and other health care professionals to assume more of the child's daily care; this can be an opportunity for the caregiver to obtain respite from daily care. Respite care may also be offered in the home by various community services, so explore these resources with families.

Assess the child's educational status. Some children attend school; others may opt for home-schooling.

Administer antidepressants as ordered: managing depression may increase the child's desire to participate in activities and self-care.

Refer the child and family to the Muscular Dystrophy Association (www.mda.org), which provides multidisciplinary care via clinics located throughout the United States. The association is also a clearinghouse for resources for individuals with muscular dystrophy.

Ensure that families receive genetic counseling for family planning purposes as well as determining which family members may be carriers for muscular dystrophy.

SPINAL MUSCULAR ATROPHY

Spinal muscular atrophy (SMA) is a genetic motor neuron disease that affects the spinal nerves' ability to communicate with the muscles. It is inherited via an autosomal recessive mechanism. The motor neuron protein SMN (survival of motor neurons) is deficient as a result of a faulty gene on chromosome 5. The motor neurons are located mostly in the spinal cord. Without adequate SMN, the signals from the neurons to the muscles instructing them to contract are ineffective, so the muscles lose function and over time atrophy. The proximal muscles, those closer to the body's center, are usually more affected than the distal muscles. Emotional and mental development as well as sensation are unaffected by the disease (Muscular Dystrophy Association, 2006c).

There are several types of SMA: type 1 (Werdnig-Hoffmann disease, infantile SMA), type 2 (intermediate), and type 3 (Kugelberg-Welander disease or juvenile SMA). Table 43.2 compares these three types, their usual progression, and their prognosis.

Respiratory muscle weakness may occur with all types of SMA and is usually the cause of death in type 1 and type 2 SMA. Upper respiratory tract infections and aspiration related to dysphagia or gastroesophageal reflux often develop into pneumonia and eventual respiratory failure, as the affected child cannot effectively cough independently in order to clear the airway. Many children with severe type 1 SMA are ventilator dependent. Pectus excavatum develops in children with type 1 and 2 SMA who exhibit paradoxical breathing (use of the diaphragm without intercostal muscle support). The chest becomes funnel-shaped and the xiphoid process is retracted (pectus excavatum), further restricting respiratory development. Inability to appropriately suck and swallow leads to difficulty feeding in the child with type 1 SMA. Weak back muscles affect the developing spine, resulting in the complication of scoliosis, kyphosis, or both.

Therapeutic management of SMA is supportive, aimed at promoting mobility, maintaining adequate nutrition and pulmonary function, and preventing complications. Spinal fusion may be performed in older children with significant scoliosis. Supplementation with creatine and/or coenzyme Q10 is under investigation (Muscular Dystrophy Association, 2006c).

Nursing Assessment

Note history of attainment of developmental milestones, as well as loss of milestones. In the infant or child with known SMA, assess for recent hospitalizations or respiratory illness. Determine the respiratory support regimen used at home (if any). Note level of motor ability, and identify the orthoses or adaptive equipment used. Elicit history related to feeding patterns at home. Assess for floppy appearance in the infant with SMA (Fig. 43.6). Note decreased ability to initiate spontaneous muscle movement. In the infant or young child with SMA, note narrow chest with decreased excursion, relatively protuberant abdomen, and paradoxical breathing pattern (Fig. 43.7). Observe chest for formation of pectus exca-

TABLE 43.2 FEATURES OF SPINAL MUSCULAR ATROPHY

Features	Type 1 SMA (Werdnig-Hoffman disease, infantile SMA)	Type 2 SMA (Intermediate SMA)	Type 3 SMA (Kugelberg-Welander disease, juvenile SMA)
Onset	Before birth to 6 months of age	6 to 18 months of age	After 18 months of age; child has started walking or has taken at least five independent steps
Symptoms	• Generalized weakness; cannot sit without support • Weak cry • Difficulty sucking, swallowing, and breathing	• Weakness that is most severe in the shoulders, hips, thighs, and upper back • Respiratory muscles may be involved. • Scoliosis may occur.	• Weakness that is most severe in the shoulders, hips, thighs, and upper back • Respiratory muscles may be involved. • Scoliosis may occur.
Progression	Rapidly progresses to early childhood death. Use of ventilators and gastrostomy feeding tubes may prolong life expectancy.	Slower progression. Survival into adulthood common if respiratory status maintained appropriately.	Slow progression. Life span usually unaffected. Walking ability maintained until at least adolescence; may need wheelchair later in life.

Data from Muscular Dystrophy Association, 2006.

vatum. Auscultate lungs for diminished or adventitious breath sounds. Monitor laboratory testing, which may include:

- Creatine kinase (CK): elevated when muscular damage is occurring
- Genetic testing: identifies presence of gene for SMA
- Muscle biopsy: shows the muscle abnormality
- Nerve conduction velocity test and electromyelogram: to determine extent of involvement

Nursing Management

Nursing management of type 2 and type 3 SMA focuses on promoting mobility, maintaining pulmonary function, and preventing complications. Children with type 1 SMA need

FIGURE 43.6 Note the hypotonic (floppy) posture of this infant with type 1 SMA (rotated arms, frog legged lower extremities). (Graphic courtesy of the Muscular Dystrophy Association, www.mda.org.)

FIGURE 43.7 Note the very narrow chest, beginning xiphoid depression, and relatively enlarged appearance of the abdomen in this infant with type 1 SMA.

additional interventions related to prevention of complications from immobility and assistance with nutrition. Refer to Nursing Care Plan Overview 43.1 for interventions related to these areas. Individualize the nursing plan of care based on the individual child's responses to the disorder.

Promote mobility through the use of range-of-motion exercises, lightweight orthotics, standing frames, and wheelchair use as appropriate. Support parents in their efforts to comply with physical and occupational therapy regimens. Older children may exercise with assistance in a warm pool. Position the child in a fashion that maintains appropriate body alignment (Fig. 43.8).

Provide chest percussion to assist with coughing and clearance of secretions. In collaboration with respiratory therapy, teach families the use of noninvasive ventilation support, in which positive pressure is delivered to the lungs through a mask or mouthpiece (Fig. 43.9). Provide routine tracheostomy care if the child has a tracheostomy (refer to tracheostomy section of Chapter 40).

Administer gastrostomy tube feedings if ordered, and teach families gastrostomy tube care. Use bracing as prescribed to prevent spinal curvature (Fig. 43.10). Make frequent inspections for skin breakdown in areas affected by bracing.

FIGURE 43.9 Use of noninvasive positive-pressure monitoring via a mask can maximize respiration and may help prevent pulmonary complications.

Cerebral Palsy

Cerebral palsy is a term used to describe a range of nonspecific clinical symptoms characterized by abnormal motor pattern and postures caused by nonprogressive abnormal brain function. The majority of causes occur before or during delivery and are often associated with brain anoxia (Box 43.1); see Healthy People 2010. Many times no specific cause can be identified. Cerebral palsy is the most common movement disorder of childhood; it is a lifelong condition and one of the most common causes of physical disability in children. The incidence is about 2.5 in every 1,000 live births (Hirtz et al., 2007). The incidence is higher in premature and twin births.

FIGURE 43.8 Position the infant with SMA to maintain appropriate body alignment, propping extremities as needed. (Graphic courtesy of the Muscular Dystrophy Association, www.mda.org.)

FIGURE 43.10 Bracing may be necessary in the young child with SMA to either prevent scoliosis from developing or prevent its progression. (Graphic courtesy of the Muscular Dystrophy Association, www.mda.org.)

BOX 43.1 Causes of Cerebral Palsy

Prenatal
- Congenital malformation
- Maternal seizures
- Maternal bleeding
- Exposure to radiation
- Environmental toxins
- Genetic abnormalities
- Intrauterine growth restriction
- Intrauterine infection, such as cytomegalovirus and toxoplasmosis
- Nutritional deficits
- Pre-eclampsia
- Multiple births
- Prematurity
- Low birthweight
- Malformation of brain structure
- Abnormalities of blood flow to the brain

Perinatal
- Prematurity (<32 weeks)
- Asphyxia
- Hypoxia
- Breech position
- Sepsis or central nervous system infection
- Placental complications
- Electrolyte disturbance
- Cerebral hemorrhage
- Kernicterus (a type of brain damage that may result from neonatal hyperbilirubinemia)
- Chorioamnionitis (infection of the placental tissues and amniotic fluid)

Postnatal
- Head trauma (e.g., motor vehicle accidents, abuse)
- Seizures
- Toxins
- Viral or bacterial infection of the central nervous system (e.g., meningitis)

Most affected children will develop symptoms in infancy or early childhood. There is a large variation in symptoms and disability. For some children it may be as mild as a slight limp; for others it may result in severe motor and neurologic impairments. Primary signs include motor impairments such as spasticity, muscle weakness, and ataxia. Complications include mental impairments, seizures, growth problems, impaired vision or hearing, abnormal sensation or perception, and hydrocephalus. Most children can survive into adulthood but may suffer substantial impairments in function and quality of life.

Pathophysiology

Cerebral palsy is a disorder caused by abnormal development of, or damage to, the motor areas of the brain.

HEALTHY PEOPLE 2010

Objective	Significance
Reduce preterm births.	• Encourage appropriate birth control use among adolescents to decrease the incidence of teen pregnancy (teens have an increased incidence of preterm delivery). • If an adolescent does become pregnant, encourage early appropriate prenatal care. • Discourage substance use among pregnant teens. • Teach pregnant teens about an appropriate diet.

It results in a disruption in the brain's ability to control movement and posture. It is difficult to establish an exact location of the neurologic lesion, and the lesion itself does not change; thus, the disorder is considered nonprogressive since the brain injury does not progress. However, the clinical manifestations of the lesion change as the child grows. Some children may improve, but many either plateau in their attainment of motor skills or demonstrate worsening of motor abilities, as it is difficult to maintain the ability to move over time.

Cerebral palsy is classified in several ways. One common way is by the type of movement disturbance (Table 43.3).

Therapeutic Management

Management involves multiple disciplines, including a primary physician, specialty physicians such as neurologist and orthopedic surgeon, nurses, physical therapists, occupational therapists, speech therapists, dietitian, psychologist, counselors, teachers, and parents. Spasticity management will be a primary concern and will be determined by clinical findings. There is no standard treatment for all children. The overall focus of therapeutic management will be to assist the child to gain optimal development and function within the limits of the disease. Treatment is mainly symptomatic, preventive, and supportive.

Medical management is focused on promoting mobility through the use of therapeutic modalities and medications. Many children will require surgical procedures to correct deformities related to spasticity. Multiple corrective surgeries may be required; they usually are orthopedic or neurosurgical. Surgery may be used to correct contractures that are severe enough to cause movement limitations. Common orthopedic procedures include tendon lengthening procedures, correction of hip and adductor muscle spasticity, and fusion of unstable joints to help improve locomotion, correct bony deformities, decrease painful spasticity, and maintain, restore, or stabilize a spinal deformity.

TABLE 43.3 CLASSIFICATION OF CEREBRAL PALSY

Types	Description	Characteristics
Spastic	Hypertonicity and permanent contractures; different types based on which limbs are affected: • Hemiplegia: both extremities on one side • Quadriplegia: all four extremities • Diplegia or paraplegia: lower extremities	• Most common form • Poor control of posture, balance, and movement • Exaggeration of deep tendon reflexes • Hypertonicity of affected extremities • Continuation of primitive reflexes • In some children, failure to progress to protective reflexes
Athetoid or dyskinetic	Abnormal involuntary movements	• Infant is limp and flaccid. • Uncontrolled slow worm-like, writhing, or twisting movements • Affects all four extremities and possible involvement of face, neck, and tongue • Movements increase during periods of stress. • Dysarthria and drooling may be present.
Ataxic	Affects balance and depth perception	• Rare form • Poor coordination • Unsteady gait • Wide-based gait
Mixed	Combination of the above	Most common is spastic and athetoid.

Neurosurgical interventions may include placement of a shunt in children who have developed hydrocephalus, or surgical interventions to decrease spasticity. Selective dorsal root rhizotomy is used to decrease spasticity in the lower extremities by reducing the amount of stimulation that reaches the muscles via nerves. The effectiveness of this surgery is controversial, and research is ongoing.

Physical, Occupational, and Speech Therapy

The use of therapies such as physical therapy, occupational therapy, and speech therapy will be essential in promoting mobility and development in the child with CP. The earlier the treatment begins, the better chance the child has of overcoming developmental disabilities.

Physical therapists work with children to assist in the development of gross motor movements such as walking and positioning, and they help the child develop independent movement. They also assist in preventing contractures, and they instruct children and caregivers in the use of assistive devices such as walkers and wheelchairs. Occupational therapists may be responsible for fashioning orthotics and splints. AFOs are the most common orthotic used by children with cerebral palsy (Fig. 43.11). AFOs help prevent deformity from conditions such as contractures and help reduce the effects of existing deformities. They can help improve a child's mobility by assisting in control of alignment and helping to increase the efficiency of the child's gait. Spinal orthotics such as braces are used in young children with cerebral palsy to combat scoliosis that develops due to spasticity. These braces are used to delay surgical management of the scoliosis until the child reaches skeletal maturity. Splinting is used to maintain muscle length. Serial casting may also be used to increase muscle and tendon length.

Occupational therapy also assists in the development of fine motor skills and will help the child to perform opti-

FIGURE 43.11 The child with cerebral palsy may benefit from wearing ankle–foot orthotics (AFOs) to provide support needed for independent or assisted walking.

mal self-care by working on skills such as activities of daily living. Speech therapy assists in the development of receptive and expressive language and addresses the use of appropriate feeding techniques in the child who has swallowing problems. Speech therapists may teach augmented communication strategies to children who are nonverbal or who have articulation problems. Many children may not communicate verbally but can use alternative means such as communication books or boards to make their desires known or to participate in conversation.

Pharmacologic Management

Various pharmacologic options are available to manage spasticity. Medications are also used to treat seizure disorders in children with cerebral palsy (refer to Chapter 38 for information related to seizure management). Oral medications used to treat spasticity include baclofen and diazepam (see Drug Guide 43.1). Patients with athetoid cerebral palsy may be given anticholinergics to help decrease abnormal movements.

Parenterally administered medications such as botulin toxins and baclofen are also used to manage spasticity. Botulinum toxin is injected into the spastic muscle to balance the muscle forces across joints and to decrease spasticity. It is useful in managing focal spasticity in which the spasticity is interfering with function, producing pain, or contributing to a progressive deformity. Botulin toxin injection is performed by the physician or advanced practitioner and can be done in the clinic or outpatient setting.

Intrathecal administration of baclofen has been shown to decrease tone, but it must be infused continuously due to its short half-life. Surgical placement of a baclofen pump will be considered in children with general spasticity that is limiting function, comfort, activities of daily living, and endurance. To test whether it is a suitable option, an intrathecal test dose of baclofen will be administered. If the trial is successful, a baclofen pump will be implanted. Once inserted, delivery of the drug can be individualized to meet the patient's unique needs. The pump needs to be replaced every 5 to 7 years and must be refilled with medication approximately every 3 months, depending on the type of pump. Complications with baclofen pump placement include infection, rupture, dislodgement, or blockage of the catheter.

Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1420. Assessment findings pertinent to cerebral palsy are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Obtain a detailed account of gestation and perinatal events (refer to Box 43.1). Common signs and symptoms reported during the health history of the undiagnosed child might include:

- Intrauterine infections
- Prematurity with intracranial hemorrhage
- Difficult, complicated, or prolonged labor and delivery
- Multiple births
- History of possible anoxia during prenatal life or birth
- History of head trauma
- Delayed attainment of developmental milestones
- Muscle weakness or rigidity
- Poor feeding
- Hips and knees feel rigid and unbending when pulled to a sitting position
- Seizure activity
- Subnormal learning
- Abnormal motor performance, scoots on back instead of crawling on abdomen, walks or stands on toes

Children known to have cerebral palsy are often admitted to the hospital for corrective surgeries or other complications of the disease, such as aspiration pneumonia and urinary tract infections. The health history should include questions related to:

- Respiratory status: Has a cough, sputum production, or increased work of breathing developed?
- Motor function: Has there been a change in muscle tone, increase in spasticity?
- Presence of fever
- Feeding and weight loss
- Any other changes in physical state or medication regimen

Physical Examination

Observe general appearance. Pay close attention to the neurologic assessment and motor assessment. Assess for delayed development, size for age, and sensory alterations like strabismus, vision problems, and speech disorders. Abnormal postures may be present. While lying supine, the infant may demonstrate scissor crossing of the legs with plantar flexion. In the prone position the infant may raise his or her head higher than normal due to arching of the back, or the opisthotonic position may be noted. The infant may also abnormally flex the arms and legs under the trunk. Primitive reflexes may persist beyond the point at which they disappear in a healthy infant. Evolution of protective reflexes may be delayed. Watch the infant or child play, crawl, walk, or climb to determine motor function and capability. Note any movement disorder. Infants with cerebral palsy may demonstrate abnormal use of muscle groups such as scooting on their back instead of crawling or walking.

Assess active and passive range of motion. Pay particular attention to muscle tone. Though an increased or decreased resistance may be noted with passive movements, **hypertonicity** is most often seen. Increased resistance to dorsiflexion and passive hip abduction are the most common early signs. Sustained **clonus** may be present after forced dorsiflexion. Lift the child by placing your hands

in the infant's or child's axillary area to assess shoulder girdle function and tone. Infants with cerebral palsy often demonstrate prolonged standing on their toes when supported in an upright standing position in this fashion. Lift the young child off the ground while the child holds your thumbs to test hand strength. Observe for presence of limb deformity, as decreased use of an extremity (as in the case of hemiparesis) may result in shortening of the extremity compared to the other one.

Laboratory and Diagnostic Tests

A complete history, physical examination, and ancillary investigations are the primary modality for establishing a diagnosis of cerebral palsy. Common supplementary laboratory and diagnostic studies ordered for the diagnosis and assessment of cerebral palsy include:

- Electroencephalogram: usually abnormal but the pattern is highly variable
- Cranial x-rays or ultrasound: may show cerebral asymmetry
- MRI or CT: may show area of damage or abnormal development but may be normal
- Screening for metabolic defects and genetic testing may be performed to help determine the cause of cerebral palsy.

These tests will help determine whether cerebral palsy is the likely cause or whether another condition may be the cause of the child's symptoms. These tests also will be important in evaluating the severity of the child's physical disabilities.

Nursing Management

Nursing management focuses on promoting growth and development by promoting mobility and maintaining optimal nutritional intake. Providing support and education to the child and family is also an important nursing function. In addition to the nursing diagnoses and related interventions discussed in the Nursing Care Plan Overview, interventions common to caring for a child with cerebral palsy follow.

Promoting Mobility

Mobility is critical to childhood development. Treatment modalities to promote mobility include physiotherapy, pharmacologic management, and surgery. Surgical procedures are discussed above. Physical or occupational therapy as well as medications may be used to address musculoskeletal abnormalities, to facilitate range of motion, to delay or prevent deformities such as contractures, to provide joint stability, to maximize activity, and to encourage the use of adaptive devices. The nurse's role in relation to the various therapies is to provide ongoing follow-through with prescribed exercises, positioning, or bracing.

▶ *Take* NOTE!

Therapeutic horseback riding has been demonstrated to improve gross motor function in children with cerebral palsy. If available in the local area, refer the child and family to the North American Riding for the Handicapped Association (NARHA) (Sterba, 2004; Sterba, 2007).

When casting, splinting, or orthotics are used, assess skin integrity frequently. Pain management may also be necessary. Nursing management of children receiving botulin toxin focuses on assisting with the procedure and providing education and support to the child and family. Nursing interventions related to baclofen include assisting with the test dose and providing preoperative and postoperative care if a pump is placed, as well as providing support and education to the child and family. Teaching Guidelines 43.2 gives information related to baclofen pump insertion.

Promoting Nutrition

Children with cerebral palsy may have difficulty eating and swallowing due to poor motor control of the throat, mouth, and tongue. This may lead to poor nutrition and problems with growth. The child may require a longer time to eat because of poor motor control. Special diets, such as soft or puréed, may make swallowing easier.

TEACHING GUIDELINES 43.2

Baclofen Pump: Patient/Family Education

- Check the incisions daily for redness, drainage, or swelling.
- Notify the physician if the child has a temperature greater than 101.5° F, or if the child has persistent incision pain.
- Avoid tub baths for 2 weeks.
- Do not allow the child to sleep on the stomach for 4 weeks after pump insertion.
- Discourage twisting at the waist, reaching high overhead, stretching, or bending forward or backward for 4 weeks.
- When the incisions have healed, normal activity may be resumed.
- Wear loose clothing to prevent irritation at the incision site.
- Carry implanted device identification and emergency information cards at all times.

Proper positioning during feeding is essential to facilitate swallowing and reduce the risk of aspiration. Speech or occupational therapists can assist in working on strengthening swallowing muscles as well as assisting in developing accommodations to facilitate nutritional intake. Consult a dietitian to ensure adequate nutrition for children with cerebral palsy. In children with severe swallowing problems or malnutrition, a feeding tube such as a gastrostomy tube may be placed.

Providing Support and Education

Cerebral palsy is a lifelong disorder that can result in severe physical and cognitive disability. In some cases disability may require complete intensive daily care of the child. Adjusting to the demands of this multifaceted illness is difficult. Children are frequently hospitalized and need numerous corrective surgeries, which places strain on the family and its finances. From the time of diagnosis, the family should be involved in the child's care. It is important to include parents in the planning of interventions and care of this child. In most cases they are the primary caregivers and will assist the child in development of functioning and skills as well as providing daily care. They will provide essential information to the health care team and will be advocates for their child throughout his or her life. It is important that nurses provide ongoing education for the child and family.

As the child grows, the needs of the family and child will change. Recognize and respect these needs. Providing daily intense care can be demanding and tiring. When a child with cerebral palsy is admitted to the hospital, this may serve as a time of respite for family and primary caregivers. Encourage respite care and provide support and encouragement. Because cerebral palsy is a lifelong condition, children will need meaningful education programs that emphasize independence in the least restrictive educational environment. Refer caregivers to local resources, including education services and support groups. United Cerebral Palsy, a national organization, can be accessed at www.ucp.org/ (1660 L Street, NW, Suite 700, Washington, D.C. 20036; 800-872-5827/202-776-0406). Easter Seals is an organization that helps children with disabilities and special needs and provides support to families (www.easterseals.com).

Refer children under age 3 years to the local early intervention service. Early intervention provides case management of developmental services for children with special needs. Each state has a coordinator for early intervention. The office of the early intervention coordinator can then direct the health care professional to the local or district early intervention office.

Additional resources for families of young children with special needs are available at www.zerotothree.org. For additional reading, recommend the book *Children with Cerebral Palsy: A Parent's Guide* by E. Geralis (published by Woodbine House).

Acquired Neuromuscular Disorders

A number of neuromuscular disorders may be acquired during childhood or adolescence. These include disorders resulting from trauma as well as those that are autoimmune and infectious in nature. Trauma or unintentional injury is a leading cause of childhood morbidity and mortality in the United States. Injuries are the leading cause of death in children younger than 1 year of age and account for a significant percentage of childhood morbidity. The child is at increased risk for trauma based on the developmental factors of physical and emotional immaturity; additionally, adolescents display belief of invincibility. The developing neuromuscular system, if injured, may be irreparable, so the injury may result in life-threatening or lifelong effects. Neuromuscular trauma includes spinal cord injury and birth trauma (addressed in Chapter 18). Autoimmune neuromuscular disorders include Guillain-Barré syndrome, myasthenia gravis, and dermatomyositis. Botulism, though uncommon in developed countries, is an important neuromuscular disorder resulting from infection.

SPINAL CORD INJURY

Spinal cord injury is damage to the spinal cord that results in loss of function. Frequent causes are trauma, such as car accidents, falls, diving into shallow water, gunshot or stab wounds, sports injuries, child abuse, or birth injuries. Spinal cord injuries are relatively uncommon in children, but when they do occur they have a devastating impact on the child's physical and functional status, social and emotional development, and family functioning. More spinal cord injuries are seen in adolescents due to their increased incidence of accidents, particularly motor vehicle accidents.

Spinal cord injury is a medical emergency and immediate medical attention is required. Cervical traction is often used initially and surgical intervention is sometimes necessary. Ongoing medical treatment will be based on the child's age and overall health and the extent and location of the injury. Therapeutic management focuses on rehabilitation and prevention of complications. Spinal cord injury in children is managed similarly to that in adults.

Nursing Assessment

Symptoms vary based on the location and severity of the injury. Common signs and symptoms associated with spinal cord injury include:

- Inability to move or feel extremities
- Numbness
- Tingling
- Weakness

The higher the injury in the spinal cord, the more extensive the damage and the greater the loss of function. High cervical injury will result in damage to the phrenic nerve, which innervates the diaphragm. Damage to this nerve will leave the child unable to breathe without assistance. Paralysis depends on the location of the injury to the spinal cord.

The diagnosis of spinal cord injury is made by clinical signs and diagnostic tests, which may include x-rays, CT, and MRI.

Nursing Management

Any child who requires hospitalization due to trauma should be considered at risk for a spinal cord injury, and immobilization of the spine is essential until full evaluation of the injury is complete and spinal cord damage is ruled out. Nursing management will be similar to management of the adult with a spinal cord injury and will focus on optimizing mobility, promoting bladder and bowel management, promoting adequate nutritional status, preventing complications associated with extreme immobility such as contractures and muscle atrophy, managing pain, and providing support and education to the child and family. Refer to the myelomeningocele section of this chapter for information related to urinary and bowel elimination.

The nurse plays an important role not only in the acute care of children with spinal cord injury but also during rehabilitation. Recovery from a spinal cord injury requires long-term hospitalization and rehabilitation. An interdisciplinary team of physicians, nurses, therapists, social workers, and case managers will work to manage the child's complex and long-term needs. Promoting communication among the interdisciplinary team is essential and will be a key nursing function. Rehabilitation will need to focus on the ever-changing developmental needs of the child as he or she grows.

Prevention of spinal cord injuries is an important nursing consideration. Educate the public on vehicular safety, including seat belt use and the proper use of age-appropriate safety seats. Additional education topics include bicycle, sports, and recreation safety, prevention of falls, violence prevention including gun safety, and water safety, including the risk of diving. This education can help decrease the incidence of spinal cord injury in children.

GUILLAIN-BARRÉ SYNDROME

Guillain-Barré syndrome (also called acute inflammatory demyelinating polyradiculoneuropathy or polyneuropathy) is an uncommon disorder in which an immune response within the body attacks the peripheral nervous system but does not usually affect the brain or spinal cord. Guillain-Barré syndrome results in inflammation and demyelinization of the peripheral nerves. It is not fully understood why this occurs, but it is believed to be an autoimmune condition that most commonly is triggered by a previous viral or bacterial infection, usually described as an influenza-like upper respiratory tract infection or an acute gastroenteritis with fever. In rare cases it has occurred after the patient has had an immunization. In most cases the causative agent remains unidentified.

Therapeutic Management

Treatment of Guillain-Barré syndrome is symptomatic and focuses on lessening the severity and speeding recovery. Plasma exchange and administration of intravenous immunoglobulins may occur, especially in severe cases. The goal of treatment is to keep the body functioning until the nervous system recovers. Guillain-Barré syndrome is a life-threatening condition, and some children will die during the acute phase due to respiratory failure. Most children will make a full recovery, but a few may have residual damage.

Nursing Assessment

Early diagnosis and prompt treatment are essential since the disorder can quickly lead to respiratory failure and death from muscle paralysis. For a full description of the assessment phase of the nursing process, refer to page 1420. Assessment findings pertinent to Guillain-Barré syndrome are discussed below.

Health History

Elicit a description of the present illness and chief complaint. The clinical presentation is fairly similar in children and adults. It can occur a few days or weeks after the causative infection or event. Guillain-Barré syndrome has a quick onset and begins with muscle weakness and paresthesias such as numbness and tingling. Classically it initially affects the legs and progresses in an ascending manner. Occasionally it affects the arms or face first and proceeds in a descending manner. Progression is usually complete in 2 to 4 weeks, followed by a stable period leading to the recovery phase, which lasts for a few weeks to months in most cases but can take years. Severity of the disorder ranges from mild weakness to total paralysis.

In children, pain, especially of the lower extremities, as the initial presentation preceding motor involvement has been reported. Other symptoms seen during the course of the illness include:

- Fairly symmetrical flaccid weakness or paralysis
- Ataxia
- Sensory disturbances

Physical Examination and Laboratory and Diagnostic Tests

Physical examination findings may include decreased or absent tendon reflexes. Facial weakness or difficulty swallowing may also be present. Diagnosis is usually based on

clinical findings of paralysis. CSF analysis may reveal an increased level of protein, but this may not be evident until after the first week of the illness.

▶ Take NOTE!

Tickling may be a successful technique for assessing the level of paralysis in the child with Guillain-Barré syndrome, either initially or in the recovery phase.

Nursing Management

Nursing management is supportive. In severe cases the child may require intensive nursing care along with mechanical ventilation. Observe the child closely for the extent of paralysis and monitor for respiratory involvement. Nursing care focuses on the same concerns as in any patient with extreme immobility or paralysis.

Prevention of complications associated with immobility is a central concern and involves maintaining skin integrity, preventing respiratory complications and contractures, maintaining adequate nutrition, and managing pain. Interventions include turning and repositioning every 2 hours, assessing the skin for redness or breakdown, performing range-of-motion exercises, keeping the skin clean and dry, encouraging intake of fluids to maintain hydration status, and encouraging coughing and deep breathing every 2 hours and as needed. Enteral feeding or parenteral nutrition may be indicated if swallowing becomes impaired. Physical therapy may be helpful in preventing complications and promoting motor skill recovery. Provide support and education to the parent and child. The rapid onset and long recovery can be difficult and can cause strain on the family and its finances. If residual disability occurs, the family will need help adjusting and caring for their child.

▶ Take NOTE!

Serial measurement of tidal volumes may reveal respiratory deterioration in the child with Guillain-Barré syndrome.

MYASTHENIA GRAVIS

Myasthenia gravis is an autoimmune disease that may be triggered by a viral or bacterial infection or by the thymus gland. The acetylcholine receptor at the neuromuscular junction is affected, inhibiting normal neuromuscular transmission. The result is progressive weakness and fatigue of the skeletal muscles. Though no gene has been discovered as responsible for myasthenia gravis, autoimmune diseases do demonstrate a genetic predisposition. Myasthenia gravis occurs in three forms: neonatal, congenital, and acquired.

Therapeutic management generally involves the use of anticholinesterase medications such as pyridostigmine, which blocks the breakdown of acetylcholine at the neuromuscular junction. Additional medications may include corticosteroids and other immunosuppressants, plasmapheresis, intravenous immunoglobulin, and, in children who have reached puberty, thymectomy (Parr & Jayawant, 2007). Myasthenia gravis usually reaches maximum severity within 1 to 3 years of onset, and with proper treatment children can remain physically active (Muscular Dystrophy Association, 2006d). It may be aggravated by stress, exposure to extreme temperatures, and infections, resulting in a myasthenic crisis.

Nursing Assessment

Note history of fatigue and weakness; difficulty chewing, swallowing, or holding up the head; or pain with muscle fatigue. In the verbal child, note complaints of double vision. Observe the child for ptosis (droopy eyelids) or altered eye movements from partial paralysis. The neonate may display inadequate suck, weak cry, floppy extremities, and, possibly, respiratory insufficiency. Note increased work of breathing. Laboratory testing may involve the edrophonium (Tensilon) test, in which a short-acting cholinesterase inhibitor is used. Acetylcholine receptor (AchR) antibodies may be present in elevated quantities in the serum.

Nursing Management

Administer anticholinergic or other medications as ordered, teaching children and families about the use of these drugs. Anticholinergic drugs should be given 30 to 45 minutes before meals, on time and exactly as ordered. Encourage families to seek prompt medical treatment for suspected infections. Encourage appropriate stress management and avoidance of extreme temperatures. Teach families that physical activities should be performed during times of peak energy; rest periods are needed for energy conservation. Teach families to call their neurologist immediately if signs and symptoms of myasthenic crisis or cholinergic crisis appear. Encourage children to wear a medical alert bracelet.

▶ Take NOTE!

Signs and symptoms of myasthenic crisis include severe muscle weakness, respiratory difficulty, tachycardia, and dysphagia. Signs and symptoms of cholinergic crisis include severe muscle weakness, sweating, increased salivation, bradycardia, and hypotension.

DERMATOMYOSITIS

Dermatomyositis is an autoimmune disease that results in inflammation of the muscles or associated tissues. It occurs more often in girls and is generally diagnosed between the ages of 5 and 14 years. The autoimmune response may be triggered by exposure to a virus or to certain medications. As with other autoimmune diseases, a genetic predisposition is present. The inflammatory cells of the immune system cause a vasculitis that affects the skin, muscles, kidneys, retinas, and gastrointestinal tract.

Therapeutic management involving the use of corticosteroids or other immunosuppressants is necessary to prevent the complications of painful calcium deposits under the skin, as well as joint contractures. With appropriate treatment, children may recover completely, though some children experience relapses (Muscular Dystrophy Association, 2006a).

Nursing Assessment

Elicit a health history, which commonly involves history of fever, fatigue, and rash, usually followed by muscle pain and weakness. Determine onset and progression of muscle weakness. Inspect the skin for presence of rash involving the upper eyelids and extensor surfaces of the knuckles, elbows, and knees. The rash is initially a reddish-purplish color, and then progresses to scaling with resulting roughness of the skin. Test muscle strength, noting particularly weakness in the pelvic and shoulder girdles. Laboratory and diagnostic testing may include muscle enzyme levels, a positive ANA test, and an electromyelogram to distinguish muscular weakness from other causes.

Nursing Management

Administer medications as ordered and teach families about their use; instruct them to monitor for side effects. Educate the family about the importance of maintaining the medication regimen in order to prevent calcinosis (calcium deposits) and joint deformity in the future. Encourage compliance with physical therapy regimens. Ensure that children are excused from physical education classes while the disease is active.

BOTULISM

Botulism is a disease that is caused by a toxin produced in the immature intestines of young children resulting from infection with the bacterium *Clostridium botulinum.* It is rare but can cause serious paralytic illness. Botulism is mainly a food-borne infection but can also be contracted through wound infections or intestinal infections in infants. *C. botulinum* is common in soil and can also be found in a variety of foods, such as improperly preserved home-canned foods. It generally occurs in infants less than 6 months of age. It has been associated with feeding honey and corn syrup to infants; thus, these should be avoided in children less than 1 year of age. The disease is not infectious; to become infected, the child must ingest the bacterial spores. These spores then multiply in the intestinal tract and produce the toxin, which is absorbed in the immature intestines of the infant. It is generally not a problem for older children because the bacteria do not grow well in mature intestines due to the presence of the normal intestinal flora. Prognosis is good, but if treatment is not initiated, paralysis of the arms, legs, trunk, and respiratory system can develop. Therapeutic management is usually supportive but may involve administration of botulinum toxin.

Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1420. Assessment findings pertinent to botulism are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Signs and symptoms usually occur soon after ingestion of the bacteria. Common signs and symptoms in infants reported during the health history might include:

- Constipation
- Poor feeding
- Listlessness
- Generalized weakness
- Weak cry

Common signs and symptoms in older children reported during the health history might include:

- Double vision
- Blurred vision
- Drooping eyelids
- Difficulty swallowing
- Slurred speech
- Muscle weakness

Physical Examination and Laboratory and Diagnostic Tests

Assess for a diminished gag reflex, which is indicative of botulism. Diagnostic tests include cultures of stool and serum. Botulism is a rare disease and is difficult to diagnose since its symptoms are similar to those of other neuromuscular diseases. Therefore, assessment may include diagnostic tests to help rule out other diseases, such as Guillain-Barré syndrome, stroke, and myasthenia gravis.

Nursing Management

Treatment is mainly supportive and focuses on maintaining respiratory status and nutritional status. If ordered, administer botulinum toxin early in the disease to reduce its severity and progression.

Key Concepts

- Muscles, tendons, ligaments, and cartilage are all present and functional at birth, though intentional, purposeful movement develops only as the infant matures.
- The spine is very mobile in the newborn and infant, especially the cervical spine region, resulting in a high risk for cervical spine injury.
- The nurse's role in laboratory and diagnostic testing for neuromuscular disorders is mainly that of educating the child and family about and preparing the child for the test or procedure.
- Assessment of range of motion and muscle tone is critical in the child with a neuromuscular disorder. Hypertonia or hypotonia is an abnormal finding in the infant or child.
- Determining attainment of developmental milestones and subsequent progression or loss of those milestones is useful in distinguishing various neuromuscular disorders.
- The nurse reinforces and carries out the exercise plans and adaptive equipment use as prescribed by the physical or occupational therapist in order to maintain neuromuscular function and to prevent complications.
- Nursing management of a child with myelomeningocele focuses on preventing infection, promoting bowel and urinary elimination, promoting adequate nutrition, preventing latex allergy reaction, maintaining skin integrity, providing education and support to the family, and recognizing complications, such as hydrocephalus or increased ICP, associated with the disorder.
- Cerebral palsy may result in significant motor impairment. Children with cerebral palsy require ongoing physical therapy as well as nutritional intervention.
- Boys with Duchenne muscular dystrophy initially learn to walk but later lose this ability.
- Respiratory compromise occurs in muscular dystrophy and spinal muscular atrophy and eventually leads to death.
- Children with spinal cord injury require intense nursing management and lengthy rehabilitation to maintain or regain function.
- Children with neuromuscular disorders often suffer depression related to the chronic nature of the disorder.
- School attendance and participation in activities such as the Special Olympics are important for children with neuromuscular dysfunction.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. A boy with Duchenne muscular dystrophy is admitted to the pediatric unit. He has an ineffective cough. Lung auscultation reveals diminished breath sounds. What is the priority nursing intervention?
   a. Apply supplemental oxygen.
   b. Notify the respiratory therapist.
   c. Monitor pulse oximetry.
   d. Position for adequate airway clearance.
2. A 7-year-old child with cerebral palsy has been admitted to the hospital. Which information is most important for the nurse to obtain in the history?
   a. Age that the child learned to walk
   b. Parents' expectations of the child's development
   c. Functional status related to eating and mobility
   d. Birth history to identify cause of cerebral palsy
3. The nurse is caring for a 2-year-old with myelomeningocele. When teaching about care related to neurogenic bladder, what response by the parent would indicate that additional teaching is required?
   a. "Routine catheterization will decrease the risk of infection from urine staying in the bladder."
   b. "I know it will be important for me to catheterize my child for the rest of her life."
   c. "I will make sure that I always use latex-free catheters."
   d. "I will wash the catheter with warm soapy water after each use."
4. The nurse is caring for a child with cerebral palsy who requires a wheelchair to attain mobility. Which intervention would help the child achieve a sense of normality?
   a. Encourage follow-through with physical therapy exercises.
   b. Restrict the child to a special needs classroom.
   c. Encourage after-school activities within the limits of the child's abilities.
   d. Ensure the school is aware of the child's capabilities.
5. What is the priority nursing intervention for the child recently admitted with Guillain-Barré syndrome?
   a. Perform range-of-motion exercises.
   b. Take temperature every 4 hours.
   c. Monitor respiratory status closely.
   d. Assess skin frequently.

CRITICAL THINKING EXERCISES

1. A 5-year-old girl, diagnosed with myelomeningocele, is admitted to the hospital for a corrective surgical procedure. Choose four questions from below that the nurse should ask when obtaining the health history that would assist in planning the child's care.
   a. What is the child's current mobility status?
   b. Is there a family history of myelomeningocele?
   c. What is the child's genitourinary and bowel function and regimen?
   d. Does this child have a history of hydrocephalus with presence of shunt?
   e. Does she have known latex sensitivity?
   f. Were there any complications during the pregnancy or birth of this child?
   g. Did the mother take prenatal folic acid supplementation?
2. Based on the case in the above question, develop a nursing care plan for the child with myelomeningocele.
3. A 5-year-old child is admitted to the pediatric unit with a history of cerebral palsy sustained at birth. The child is admitted for a scheduled tendon lengthening procedure. Based on your knowledge about the effects of cerebral palsy, list three priorities to focus on when planning her care. Compare this to a child admitted for surgical correction of a broken femur with no significant past medical history.

STUDY ACTIVITIES

1. In the clinical setting, compare the growth of a child with muscular dystrophy, spinal muscular atrophy, or cerebral palsy to the growth of a similar-age child who has been healthy. What differences or similarities

do you find? What are the explanations for your findings?

2. Identify the role of the registered nurse in the multidisciplinary care of the child with a debilitating neuromuscular disorder.

3. In the clinical setting, interview the parent of a child with Duchenne muscular dystrophy, myelomeningocele, spinal muscular atrophy, or severe cerebral palsy. Determine the parent's feelings about the ongoing care that he or she is responsible for. Reflect upon this interview in your clinical journal.

4. In the clinical setting, compare the cognitive abilities of two children with a severe neuromuscular disorder. What are the reasons for the similarities or differences that you find?

CHAPTER 44

Nursing Care of the Child With a Musculoskeletal Disorder

KEY TERMS

compartment syndrome
distraction
epiphysis
external fixation
immobilize
kyphosis
lordosis
ossification
splint
traction
Trendelenburg gait

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Compare the anatomy and physiology of the musculoskeletal system in children versus adults.
2. Identify nursing interventions related to common laboratory and diagnostic tests used in the diagnosis and management of musculoskeletal disorders.
3. Identify appropriate nursing assessments and interventions related to medications and treatments for common childhood musculoskeletal disorders.
4. Distinguish various musculoskeletal disorders occurring in childhood.
5. Devise an individualized nursing care plan for the child with a musculoskeletal disorder.
6. Develop patient/family teaching plans for the child with a musculoskeletal disorder.
7. Describe the impact of chronic musculoskeletal disorders on the growth and development of children.

Dakota Dawes, 2 years old, is brought to the clinic by his mother. She states, "Last night Dakota said his arm hurt, but he didn't have any complaints during the day. Today when he was playing I noticed he wasn't using his right arm."

Wow

Nursing care that heals children to take wobbly steps, run, jump, fall, and get up again provides life itself in a child's world.

A variety of musculoskeletal disorders may affect children, but the result of each is motor dysfunction. Understanding the most common responses to these disorders gives the nurse the foundation required to plan care for any child with any musculoskeletal disorder.

Variations in Pediatric Anatomy and Physiology

Musculoskeletal disorders in children may occur as a congenital malformation or a genetic disorder that is present from birth but may not be identified until later in childhood or adolescence. Some disorders are developmental; others result from trauma. The infant and young child have resilient soft tissue, so sprains and strains are less common in this age group. Older school-age children and adolescents often participate in sports, resulting in an increased risk of injuries such as sprains, fractures, and torn ligaments. The musculoskeletal system in infants and children is immature compared with adults; thus, when a musculoskeletal problem occurs in childhood, the child's growth may be hindered. The immobility associated with most musculoskeletal disorders may affect the child's development and acquisition of motor skills.

Myelinization

Myelinization of the central nervous system continues to progress after birth and is complete by about 2 years of age. Myelinization proceeds in a cephalocaudal and proximal–distal fashion, allowing voluntary muscle control to progress as myelinization occurs. As myelinization proceeds, the speed and accuracy of nerve impulses increase. Primitive reflexes are replaced with voluntary movement.

Muscle Development

The muscular system, including tendons, ligaments, and cartilage, arises from the mesoderm in early embryonic development. At birth (term or preterm), the muscles, tendons, ligaments, and cartilage are all present and functional. The newborn infant is capable of spontaneous movement but lacks purposeful control. Full range of motion is present at birth. Healthy infants and children demonstrate normal muscle tone. As the infant matures and becomes mobile, the muscles develop further and become stronger and their mass increases. The infant's muscles account for approximately 25% of total body weight, as compared with the adult's muscle mass, which accounts for about 40% of total body weight. Muscles grow rapidly in adolescence; this contributes to clumsiness, which places the teen at increased risk for injury. In response to testosterone release, the adolescent boy experiences a growth spurt, particularly in the trunk and legs, and develops bulkier muscles. Female infants tend to have laxer ligaments than male infants, possibly due to the presence of female hormones, placing them at increased risk for developmental dysplasia of the hip.

Skeletal Development

The infant's skeleton is not fully ossified at birth. The skeleton contains increased amounts of cartilage compared with adolescents and adults. The infant and young child's bones are more flexible and more porous and have a lower mineral content than the adult's. These structural differences of a young child's bones allow for greater shock absorption, so the bones will often bend rather than break when an injury occurs. The thick, strong periosteum of the child's bones allows for a greater absorption of force than is seen in adults. As a result, the cortex of the bone does not always break, sometimes buckling or bending only. **Ossification** and conversion of cartilage to bone continue throughout childhood and are complete at adolescence.

During fetal development the spine displays **kyphosis**. Cervical **lordosis** develops as the infant starts to hold the head up. When the infant or toddler assumes an upright position, the primary and secondary curves of the spine begin to develop. The balance of the curves allows the head to be centered over the pelvis. During the toddler years, the period of early walking, lumbar lordosis may be significant (also termed toddler lordosis), and the toddler appears quite swaybacked and potbellied. As the child develops, the spine takes on more adult-like curves. During adolescence thoracic kyphosis may become evident. This is most often a postural effect, and as the teen matures, the posture appears similar to that of an adult.

Growth Plate

The ends of the bones in young children are composed of the **epiphysis** and the physis, in combination termed the growth plate. In infants, the epiphyses are cartilaginous and ossify over time. In children, the epiphysis is the secondary ossification center at the end of the bone. The physis is a cartilaginous area between the epiphysis and the metaphysis. Growth of the bones occurs primarily in the epiphyseal region. This area is vulnerable and structurally weak. Traumatic force applied to the epiphysis during injury may result in fracture in that area of the bone. Epiphyseal injury may result in early, incomplete, or partial closure of the growth plate, leading to deformity or shortening of the bone. Epiphyseal growth continues until skeletal maturity is reached during adolescence. Production of androgens in adolescence gradually causes the growth plates to fuse, and thus long bone growth is complete (Fig. 44.1).

Bone Healing

The child's bones have a thick, strong periosteum with an abundant blood supply. Bone healing occurs in the same fashion as in the adult, but because of the rich nutrient supply to the periosteum, it occurs more quickly in children. Children's bones produce callus more rapidly and in

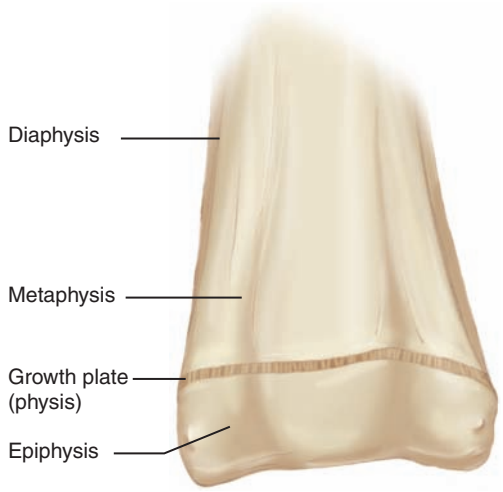

FIGURE 44.1 Anatomic areas of growing bone.

larger quantities than do adults'. As new bone cells quickly form, a bulge of new bone growth occurs at the site of the fracture. The younger the child, the more quickly the bone heals. Also, the closer the fracture is to the growth plate (epiphysis), the more quickly the fracture heals. The capacity for remodeling (the process of breaking down and forming new bone) is increased in children as compared with adults. This means that straightening of the bone over time occurs more easily in children.

Positional Alterations

The lower extremities of the infant tend to have a bowed appearance, attributed to *in utero* positioning. *In utero,* the fetus' hips are usually flexed, abducted, and externally rotated, with the knees also flexed and the lower limbs inwardly rotated (Fig. 44.2). This normal developmental variation is termed internal tibial torsion. The legs straighten with passive motion, and internal tibial torsion should not be confused with "bowlegs." Internal tibial torsion usually resolves independently some time in the second or third year of life as the toddler bears weight and the lower extremity muscles and bones mature. The bowlegged appearance is sometimes also referred to as genu varum. As internal tibial torsion or genu varum resolves, physiologic genu valgum occurs. Children usually demonstrate symmetric genu valgum (knock-knees) by the age of 2 to 3 years. In genu valgum, when the knees are touching the ankles are significantly separated, with the lower portion of the legs angled outward (Fig. 44.3). By age 7 or 8 years, genu valgum gradually resolves in most children.

FIGURE 44.2 Internal tibial torsion with metatarsus adductus—normal findings in the infant.

FIGURE 44.3 Genu valgum (knock-knees): note knees touching at midline and outward angle of the lower half of the legs.

The newborn's feet also display in-toeing (metatarsus adductus) as a result of *in utero* positioning (see Fig. 44.2). The feet remain flexible and may be passively moved to midline and in a straight position. This also resolves as the infant's musculoskeletal system matures. Pes planus (flat feet) is noted in infants when they begin to walk. The long arch of the foot is not yet developed and makes contact with the floor, resulting in a medial bulge. As the child grows and the muscles become less lax, the arch generally develops. Some children may continue with flexible flat feet, and this is considered a normal variation.

▶ *Take* NOTE!

Fractures are rare in children less than 1 year of age. The infant who presents with a fracture should be carefully evaluated for child abuse or an underlying musculoskeletal disorder.

Common Medical Treatments

A variety of medications as well as other medical treatments are used to treat musculoskeletal disorders in children. Most of these treatments will require a physician's order when the child is in the hospital. The most common treatments and medications are listed in Common Medical Treatments 44.1 and Drug Guide 44.1. The nurse caring for the child with a musculoskeletal disorder should become familiar with what the procedures are, how they work, as well as common nursing implications related to use of these modalities. The treatment of musculoskeletal disorders often involves immobilization via casting, bracing, splinting, or traction to allow healing with the bones in appropriate alignment. The length of treatment with these immobilization methods varies from weeks to months depending on the type of disorder being treated and its severity. Complications related to casting and traction include neurovascular compromise, skin integrity impairment, soft tissue injury, **compartment syndrome**, and, with skeletal traction, pin site infection or osteomyelitis.

COMMON MEDICAL TREATMENTS 44.1

Treatment	Explanation	Indication	Nursing Implications
Traction	Application of a pulling force on an extremity or body part	Fracture reduction, dislocations, correction of deformities	To maintain even, constant traction: • Ensure weights hang free at all times and ropes remain in the pulley grooves. • Keep weights out of child's reach. • Maintain prescribed weight. • Elevate head or foot of bed only with physician order. Monitor for complications: • Perform neurovascular checks at least every 4 hours. • Assess for skin impairment.
Casting	Application of plaster or fiberglass material to form a rigid apparatus to immobilize a body part	Fracture reduction, dislocations, correction of deformities	Assess frequently for neurovascular compromise, skin impairment at cast edges. Protect cast from moisture. Teach family how to care for cast at home.
Splinting	Temporary stiff support of injured area	Temporary fracture reduction, immobilization and support of sprains	Similar to cast care. Some splints are removable and are replaced when the child is up out of bed. Teach family appropriate use of splints.
Fixation	Surgical reduction of a fracture or skeletal deformity with an internal or external pin or fixation device	Fractures, skeletal deformities	No additional care for internal fixation. External fixation: perform pin care as prescribed by the surgeon. Assess for excess drainage or pin slippage, notifying physician if this occurs. Velcro or snaps on sleeves and pant legs help with dressing.
Cold therapy	Application of ice bags, commercial cold packs, or cold compresses	Most often used in acute injuries to cause vasoconstriction, thereby decreasing pain and swelling	Apply for 20 to 30 minutes, then remove for 1 hour, then reapply for 20 to 30 minutes. Discontinue when numbness occurs. Place a towel between the cold pack and the skin to prevent thermal injury.
Crutches	Ambulatory devices that transfer body weight from lower to upper extremities	Used whenever weight bearing is contraindicated	Top of crutch should reach 2 to 3 finger-breadths below the axillae to prevent nerve palsy. Teach child appropriate ambulation with crutches or reinforce teaching if performed by physical therapist.

Treatment	Explanation	Indication	Nursing Implications
Physical therapy, occupational therapy	Physical therapy focuses on attainment or improvement of gross motor skills. Occupational therapy focuses on refinement of fine motor skills, feeding, and activities of daily living.	Restore function after injury or surgery; promote developmental activities when limb use is compromised, as in limb deficiency	Provide follow-through with prescribed exercises or supportive equipment. Success of therapy is dependent upon continued compliance with the prescribed regimen. Ensure adequate communication exists within the interdisciplinary team.
Orthotics, braces	Adaptive positioning devices specially fitted for each child by the physical or occupational therapist or orthotist. Used to maintain proper body or extremity alignment, improve mobility, and prevent contractures.	Used to immobilize a body part or prevent deformity through positioning. Used to treat developmental dysplasia of the hip and scoliosis; also may be used for a period of time after cast removal.	Provide frequent assessments of skin covered by the device to avoid skin breakdown. Cotton undergarment worn under the brace helps to maintain skin integrity. Follow the therapist's schedule of recommended "on" and "off" times. Encourage families to comply with use.

DRUG GUIDE 44.1 COMMON DRUGS FOR MUSCULOSKELETAL DISORDERS

Medication	Action	Indication	Nursing Implications
Benzodiazepines (diazepam, lorazepam)	Antianxiety drugs that also have the effect of skeletal muscle relaxation	Treatment of muscle spasms associated with traction or casting	Monitor sedation level. May cause dizziness. Paradoxical excitement may occur. Assess for improvements in spasms.
Acetaminophen	Blocks pain impulses in response to inhibition of prostaglandin synthesis	Relief of mild pain if used alone, moderate or severe pain if used with a narcotic analgesic	Often combined with a narcotic such as codeine or oxycodone for increased analgesic effect. Monitor pain levels and response to medication.
Narcotic analgesics	Act on receptors in the brain to alter perception of pain	Relief of moderate to severe pain associated with injuries, orthopedic procedures	Assess pain location, quality, intensity, and duration. Assess respiratory rate prior to and periodically after administration. Monitor sedation level. May cause nausea, vomiting, constipation, pupil constriction.
Nonsteroidal anti-inflammatory drugs (NSAIDs: ibuprofen, ketorolac)	Inhibit prostaglandin synthesis, having a direct inhibitory effect on pain perception	Relief of mild to moderate pain, treatment of Legg-Calvé-Perthes disease	Monitor for nausea, vomiting, diarrhea, constipation. Administer with water or food to decrease GI upset.
Bisphosphonate: IV—pamidronate, zoledronic acid; oral—alendronate, risedronate	Increase bone mineral density	Decrease incidence of fractures in moderate to severe osteogenesis imperfecta	IV: given at 4-month intervals, causes a decrease in serum calcium level, influenza-like reaction with first IV dose. Oral: side effects include heartburn, regurgitation, upper abdominal discomfort.

Casts

Casts are used to **immobilize** a bone that has been injured or a diseased joint. When a fracture has occurred, a cast serves to hold the bone in reduction, thus preventing deformity as the fracture heals. Casts are constructed of a hard material, traditionally plaster but now more commonly fiberglass. The hard nature of the cast keeps the bone aligned so that healing may occur more quickly. In a fracture that would heal on its own without specific immobilization, a cast may be used to reduce pain and to allow the child increased mobility. The choice of cast material and type of cast will be determined by the pediatrician or orthopedic surgeon. Table 44.1 shows selected casts used in children.

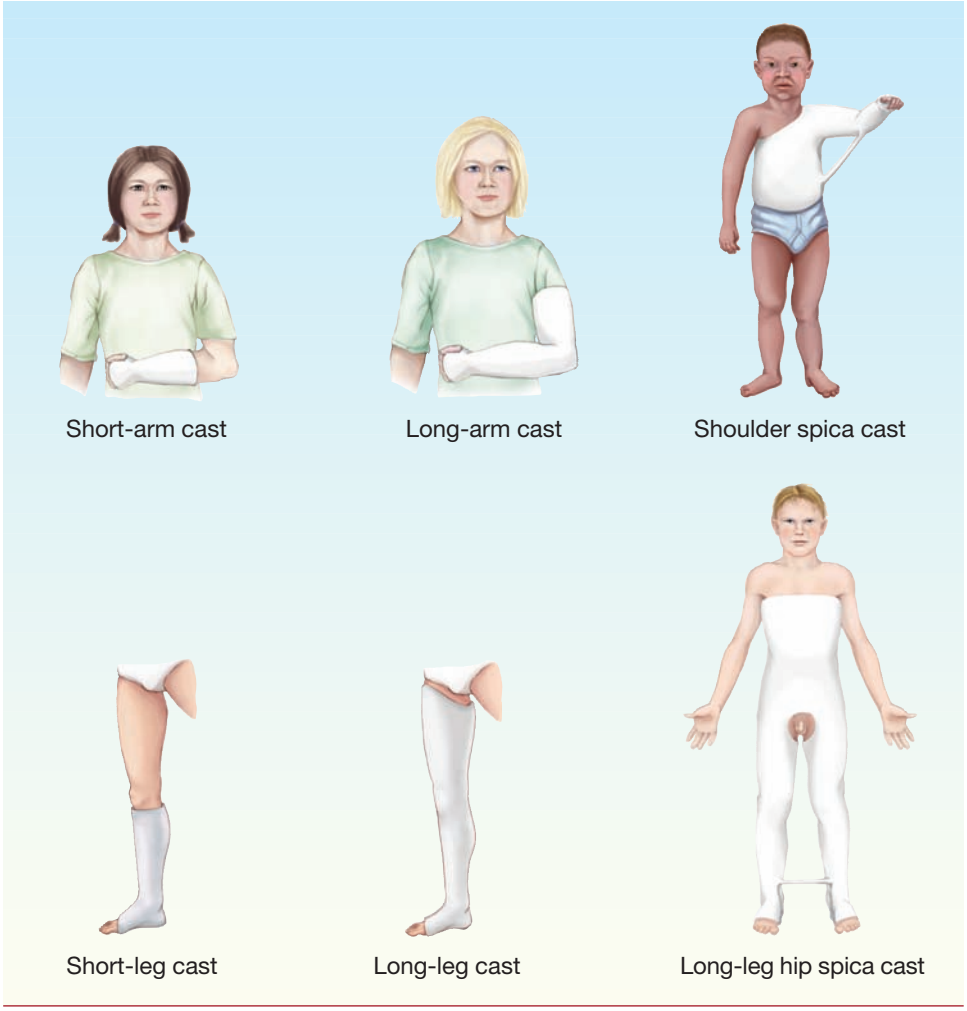
Traction

Traction, another common method of immobilization, may be used to reduce and/or immobilize a fracture, to align an injured extremity, and to allow the extremity to be restored to its normal length. Traction may also reduce pain by decreasing the incidence of muscle spasm. In running traction, the weight pulls directly on the extremity in only one plane. This may be achieved with either skin or skeletal traction. In balanced suspension traction, additional weights are used to provide a counterbalance to the force of traction. This allows for constant pull on the extremity even if the child changes position somewhat. Comparison Chart 44.1 discusses skin versus skeletal traction.

External Fixation

External fixation may be used for complicated fractures, especially open fractures with soft tissue damage. A series of pins or wires are inserted into bone and then attached to an external frame. The fixator apparatus may be adjusted as needed by the health care provider. Once the desired level of correction is achieved, no further adjustment occurs and the bone is allowed to heal. Advantages of external fixation include increased patient

TABLE 44.1 Selected Casts Used in Children



COMPARISON CHART 44.1 SKIN VERSUS SKELETAL TRACTION

	Skin Traction	Skeletal Traction
Application of force	To the skin via strips or tapes secured with Ace bandages or traction boots	To the body part directly by fixation into or through the bone
Length of treatment	Usually limited	Allows for longer periods of traction
Amount of force	Less	More

comfort and improved function of muscles and joints when complicated fracture occurs.

NURSING PROCESS OVERVIEW FOR THE CHILD WITH A MUSCULOSKELETAL DISORDER

Care of the child with a musculoskeletal disorder includes assessment, nursing diagnosis, planning, interventions, and evaluation. There are a number of general concepts related to the nursing process that may be applied to musculoskeletal dysfunction in children. The nursing care of immobilized children is similar to that of adults, yet developmental and age-appropriate effects must be taken into account. Prevention of complications is a key nursing function. Nursing Care Plan Overview 44.1 gives interventions related to prevention of complications. Particular care related to casts, traction, and fixators is discussed below.

Assessment

Assessment of musculoskeletal dysfunction in children includes health history, physical examination, and laboratory and diagnostic testing.

Remember Dakota, the 2-year-old with right arm pain and refusal to use his arm? What additional health history and physical examination assessment information should the nurse obtain?

Health History

The health history comprises past medical history, family history, and history of present illness (when the symptoms started and how they have progressed) as well as treatments used at home. The past medical history might be significant for musculoskeletal congenital anomaly or orthopedic injury during the birthing process. Breech delivery may be associated with developmental dysplasia of the hip. Determine history related to attainment of developmental milestones, such as walking and whether or not the child participates in sports. Inquire about the child's usual level of physical activity, participation in sports, and use of protective equipment. Family history may be positive for orthopedic problems. When eliciting the history of the present illness, inquire about the following:

- Limp or other changes in gait
- Recent trauma (determine the mechanism of injury)
- Recent strenuous exercise
- Fever
- Weakness
- Alteration in muscle tone
- Areas of redness or swelling

Physical Examination

Physical examination of the musculoskeletal system consists of inspection, observation, and palpation.

Inspection and Observation

Observe the child's posture and alignment of the trunk. Inspect extremities for symmetry and positioning and for absence, duplication, or webbing of any digits. Note any obvious extremity deformity or limb-length discrepancy. Inspect skin for redness, warmth, bruises, and puncture sites. Observe gait in the child who has achieved the developmental skill of walking. Note refusal to walk, limp, in-toeing, out-toeing, or foot slap. Inspect injured joints for ecchymosis or swelling. In the injured extremity, note color of fingertips or toes. Observe spontaneous range of motion. Perform scoliosis screening to determine spinal alignment. Note symmetry of thigh folds.

Palpation

Palpate the clavicles in the newborn or young infant for tenderness or a bump that indicates callus formation with clavicle fracture. Perform active range of motion to determine if a joint position is fixed (e.g., clubfoot). Palpate the affected joint or extremity to detect warmth or tenderness. In the injured child or the child with a cast or splint, thoroughly assess the neurovascular status of the affected extremities. Palpate the fingers or toes for warmth. Determine the capillary refill time. Note presence of sensation or motion. Evaluate muscle strength. Palpate pulses distal to the injury, noting their strength and quality. Perform the Ortolani and Barlow maneuvers to assess for developmental dysplasia of the hip.

(*text continues on page 1462*)

Nursing Care Plan 44.1

Overview for the Child With a Musculoskeletal Disorder

NURSING DIAGNOSIS: Impaired physical mobility related to injury, pain, or weakness as evidenced by inability to move an extremity, to ambulate, or to move without limitations

Outcome Identification and Evaluation

Child will engage in physical activities within limits of injury or disease: *child will assist with transfers and positioning in bed and/or participate in prescribed bed exercises.*

Intervention: Maximizing Physical Mobility

- Assess child's ability to move based upon injury or disease and within limits of prescribed treatment *to determine baseline.*
- Prior to prescribed exercise or major position changes, ensure that pain medication is given: *relief of pain increases child's ability to tolerate and participate in activity.*
- Use passive and active range-of-motion exercises and teach child and family how to perform them *to facilitate joint mobility and muscle development (active ROM) and to help increase mobility (within limits of restrictions related to injury or prescribed treatment).*
- Praise accomplishments and emphasize child's abilities *to improve self-esteem and encourage feelings of confidence and competence.*
- Teach child and family necessary care related to mobility issues *so the family can continue with these measures at home.*

NURSING DIAGNOSIS: Risk for constipation related to immobility and/or use of narcotic analgesics

Outcome Identification and Evaluation

Child will demonstrate adequate stool passage, *will pass soft, formed stool every 1 to 3 days without straining or other adverse effects.*

Intervention: Promoting Appropriate Bowel Elimination

- Assess usual pattern of stooling *to determine baseline and identify potential problems with elimination.*
- Palpate for abdominal fullness and auscultate for bowel sounds *to assess for bowel function and presence of constipation.*
- Encourage fiber intake *to increase frequency of stools.*
- Ensure adequate fluid intake *to prevent formation of hard, dry stools.*
- Encourage activity within child's limits or restrictions *as even minimal activity increases peristalsis.*

NURSING DIAGNOSIS: Self-care deficit related to immobility as evidenced by inability to perform hygiene care and transfer self independently

Outcome Identification and Evaluation

Child will demonstrate ability to care for self within age parameters and limits of disease: *child is able to feed, dress, and manage elimination within limits of injury or disease and age.*

Intervention: Maximizing Self-care

- Introduce child and family to self-help methods as soon as possible *to promote independence from the beginning.*
- Encourage family and staff to allow child to do as much as possible *to allow child to gain confidence and independence.*
- Collaborate with physical therapy and occupational therapy as needed to provide child and family with appropriate tools to modify environment and methods to promote transferring and self-care *to allow for maximum functioning.*
- Praise accomplishments and emphasize child's abilities *to improve self-esteem and encourage feelings of confidence and competence.*
- Balance activity with periods to rest *to reduce fatigue and increase energy available for self-care.*

Nursing Care Plan 44.1 (continued)

NURSING DIAGNOSIS: Risk for impaired skin integrity related to immobility, casting, traction, use of braces or adaptive devices

Outcome Identification and Evaluation

Child's skin will remain intact, *without evidence of redness or breakdown.*

Intervention: Promoting Skin Integrity

- Monitor condition of entire skin surface at least daily *to provide baseline and allow for early identification of areas at risk.*
- Avoid excessive friction or harsh cleaning products *that may increase risk of breakdown in child with susceptible skin.*
- Keep child's skin free from stool and urine *to decrease risk of breakdown.*
- Keep linen free from food crumbs and wrinkles *to prevent pressure areas from forming.*
- Change child's position frequently *to decrease pressure on susceptible areas.*
- Monitor condition of skin affected by braces or adaptive equipment frequently *to prevent skin breakdown related to poor fit.*

For the child in traction:

- Pad bony prominences with cotton padding before applying traction *to protect skin from injury.*
- Gently massage child's back and sacrum with lotion *to stimulate circulation.*

For the child in a spica cast:

- Apply plastic wrap to the perineal edges of the cast *to prevent soiling of cast edges, which can contribute to cast breakdown.*
- Use a fracture bedpan *to facilitate toileting without soiling cast.*
- For the child still in diapers, tuck a smaller diaper under the perineal edges of cast and cover with a larger diaper *to prevent cast soiling.*

NURSING DIAGNOSIS: Deficient knowledge related to cast care, activity restrictions, or other prescribed treatment as evidenced by verbalization, questions, or actions demonstrating lack of understanding regarding child's condition or care

Outcome Identification and Evaluation

Child and family will demonstrate accurate understanding about condition and course of treatment *through verbalization and return demonstration.*

Intervention: Providing Patient and Family Teaching

- Assess child's and family's willingness to learn: *child and family must be willing to learn for teaching to be effective.*
- Provide teaching at an appropriate level for the child and family (depends on age of child, physical condition, memory) *to ensure understanding.*
- Teach in short sessions: *many short sessions are more helpful than one long session.*
- Repeat information *to give family and child time to learn and understand.*
- Provide reinforcement and rewards *to facilitate the teaching/learning process.*
- Use multiple modes of learning involving many senses (provide written, verbal, demonstration, and videos) when possible: *child and family are more likely to retain information when presented in different ways using many senses.*

NURSING DIAGNOSIS: Risk for delayed development related to immobility, alterations in extremities

Outcome Identification and Evaluation

Development will be enhanced; *child will make continued progress toward developmental milestones and will not show regression in abilities.*

Intervention: Promoting Development

- Screen for developmental capabilities *to determine child's current level of functioning.*
- Offer age-appropriate toys, play, and activities (including gross motor) *to encourage further development.*
- Perform exercises or interventions as prescribed by physical or occupational therapist: *repeat participation in those activities helps to promote function and acquisition of developmental skills.*
- Provide support to families: *immobility and extremity deficits may lead to slow progress in achieving developmental milestones, so ongoing motivation is needed.*

▶ Take NOTE!

Assess the injured site last, and do so gently.

Laboratory and Diagnostic Testing

Common Laboratory and Diagnostic Tests 44.1 explains the laboratory and diagnostic tests most commonly used when considering musculoskeletal disorders. The tests can assist the physician in diagnosing a disorder and/or be used as guidelines in determining ongoing treatment. Some of the tests are obtained by laboratory or nonnursing personnel, while others might be obtained by the nurse. In either instance the nurse should be familiar with how the tests are obtained, what they are used for, and normal versus abnormal results. This knowledge will also be necessary when providing patient and family education related to the tests.

Nursing Diagnoses, Goals, Interventions, and Evaluation

Upon completion of a thorough assessment, the nurse might identify several nursing diagnoses, including:

- Pain (see Chapter 35)
- Impaired physical mobility
- Risk for constipation
- Self-care deficit
- Risk for impaired skin integrity
- Deficient knowledge
- Risk for developmental delay

After completing an assessment of Dakota, the nurse noted the following: the history revealed he had been sledding with his older brother the day before. Upon examination, bruising and swelling of the right arm are noted, with point tenderness at the wrist. Based on the assessment findings, what would your top three nursing diagnoses be for Dakota?

Nursing goals, interventions, and evaluation for the child with musculoskeletal dysfunction are based on the nursing diagnoses (see Nursing Care Plan Overview 44.1). The nursing care plan may be used as a guide in planning nursing care for the child with a musculoskeletal disorder. The care plan includes many nursing diagnoses that are applicable to the child or adolescent. Children's responses to musculoskeletal dysfunction and its treatment will vary, and nursing care should be individualized based on the child's and family's responses to illness.

The nursing care of immobilized children is similar to that of adults but developmental and age-appropriate effects must be taken into account. Prevention of complications is a key nursing function. Refer to Nursing Care Plan 44.1 for interventions related to prevention of complications. Additional information about nursing care related to certain disorders will be included later in the chapter as it relates to specific disorders. Refer to Chapter 35 for nursing interventions related to pain management. Particular care related to casts, traction, and external fixation is discussed below.

Based on your top three nursing diagnoses for Dakota, describe appropriate nursing interventions.

Assisting with Cast Application

Before cast or splint application, perform baseline neurovascular assessment for comparison after immobilization. Include:

- Color (note cyanosis or other discoloration)
- Movement (note inability to move fingers or toes)
- Sensation (note whether loss of sensation is present)
- Edema
- Quality of pulses

Enlist the cooperation of the child and reduce his or her fear by showing the child the cast materials and using an age-appropriate approach to describe cast application. Premedicate as ordered to reduce pain when manual traction is applied to align the bone. Use **distraction** throughout cast application and assist with application of the cast or splint (Fig. 44.4).

▶ Take NOTE!

Modern fiberglass cast materials are available in a variety of colors, as well as a few patterns. Allowing the child to choose the color will increase the child's cooperation with the procedure.

After the cast or splint is applied, drying time will vary based on the type of material used. Splints and fiberglass casts usually take only a few minutes to dry and will cause a very warm feeling inside the cast, so warn the child that it will begin to feel very warm. Plaster requires 24 to 48 hours to dry. Take care not to cause depressions in the plaster cast while drying, as those may cause skin pressure and breakdown. Instruct the child and family to keep the cast still, positioning it with pillows as needed.

Caring for the Child With a Cast

Perform frequent neurovascular checks of the casted extremity to identify signs of compromise early. These signs include:

- Increased pain
- Increased edema
- Pale or blue color

COMMON LABORATORY AND DIAGNOSTIC TESTS 44.1

Test	Explanation	Indication	Nursing Implications
X-rays	Radiographic image; usually two views are obtained of the affected extremity (lateral and anteroposterior)	To detect fractures and other anomalies	Child must cooperate and hold still. Enlist the family's help in calming the child.
Ultrasound	Use of sound waves to locate the depth and structure within soft tissues and fluid	To diagnose toxic synovitis, Legg-Calvé-Perthes disease, slipped capital femoral epiphysis, osteomyelitis, fractures, ligament or soft tissue injuries. Monitoring and follow-up of fractures and remodeling.	Better tolerated by nonsedated children than CT or MRI. Can be performed with a portable unit at bedside.
Computed tomography (CT)	Noninvasive x-ray study that looks at tissue density and structures. Images a "slice" of tissue.	To evaluate the extent of osteomyelitis, Legg-Calvé-Perthes disease, or slipped capital femoral epiphysis or to rule out other problems	Machine is large and can be frightening to children. Procedure can be lengthy and child must remain still. If unable to do so, sedation may be necessary. If performed with contrast medium, assess for allergy. Encourage fluids after the procedure if not contraindicated.
Magnetic resonance imaging (MRI)	Based on how hydrogen atoms behave in a magnetic field when disturbed by radiofrequency signals. Does not require ionizing radiation. Provides a 3D view of the body part being scanned.	To assess hard and soft tissue, as well as bone marrow, to evaluate extent of osteomyelitis, Legg-Calvé-Perthes disease, or slipped capital femoral epiphysis, or to rule out other problems	Remove all metal objects from the child. Child must remain motionless for entire scan; parent can stay in room with child. Younger children will require sedation in order to be still. A loud thumping sound occurs inside the machine during the scan procedure, and this can be frightening to children.
Arthrography	X-ray of a joint after direct injection with a radiopaque substance	To assess ligaments, muscles, tendons, and cartilage, particularly after injury	Should not be performed if joint infection is present. Apply cold therapy afterward and assess for swelling and pain. Crepitus may be present in the joint for 1 to 2 days after procedure.
Complete blood count	Evaluates hemoglobin and hematocrit, white blood cell count, platelet count	To evaluate hemoglobin and hematocrit with fracture with potential bleeding. To determine infection in osteomyelitis, septic arthritis, and toxic synovitis.	Normal values vary according to age and gender. White blood cell count differential is helpful in evaluating for infection. May be affected by myelosuppressive drugs.
Erythrocyte sedimentation rate	Nonspecific test used to determine presence of infection or inflammation	To evaluate for osteomyelitis or septic arthritis	Send sample to laboratory immediately; if allowed to stand for longer than 3 hours, may produce falsely low result.

(continued)

COMMON LABORATORY AND DIAGNOSTIC TESTS 44.1 (continued)

Test	Explanation	Indications	Nursing Implications
C-reactive protein	Measures acute-phase reactant protein indicative of inflammatory process	To evaluate for osteomyelitis or septic arthritis	Anti-inflammatory drugs may cause decreased levels. More sensitive and rapidly responsive than erythrocyte sedimentation rate.
Blood culture	To determine presence of bacteria in blood	May be positive with septic arthritis or osteomyelitis	Transport specimen to laboratory within 30 minutes. Avoid skin contamination of specimen while obtaining it. Cultures should usually be drawn before starting antibiotics, as partial antibiotic treatment may result in negative culture.
Joint fluid aspiration	Aspirated joint fluid is examined for presence of pus and white blood cells; culture is performed.	To evaluate for septic arthritis	Use cold therapy to decrease swelling after aspiration. Apply pressure dressing to prevent hematoma formation or fluid re-collection. Assess for fever and joint pain or edema, which may indicate infection. Positive fluid culture indicates a bacterial infection in the joint. May also be used to relieve pressure in the joint space.

- Skin coolness
- Numbness or tingling
- Prolonged capillary refill
- Decreased pulse strength (or absence of pulse)

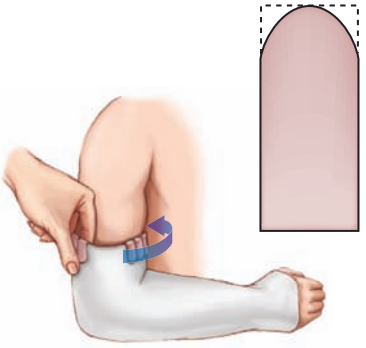
Notify the physician of changes in neurovascular status or odor or drainage from the cast.

Fiberglass casts usually have a soft fabric edge, so they usually do not cause skin rubbing at the edges of the cast. On the other hand, plaster casts require special treatment of the cast edge to prevent skin rubbing. This may be accomplished through a technique called petaling: cut rounded-edge strips of moleskin or another soft material with an adhesive backing and apply them to the edge of cast, as shown in Figure 44.5.

FIGURE 44.4 Assist with cast application by distracting or comforting the child.

▶ *Take* NOTE!

Persistent complaints of pain may indicate compromised skin integrity under the cast.



To petal a cast:

1. Cut several strips of adhesive tape or moleskin three to four inches in length. Use one inch tape for smaller areas (e.g., infant's foot) and two inch tape for larger areas (e.g., adolescent's waist).
2. Round one end of each strip to keep the corners from rolling.
3. Apply the first strip by tucking the straight end inside the cast and by bringing the rounded end over the cast edge to the outside.
4. Repeat the procedure, overlapping each additional strip, until all rough edges are completely covered.

FIGURE 44.5 Petaling the cast.

Position the child with the casted extremity elevated on pillows. Ice may be applied during the first 24 to 48 hours after casting if needed. Teaching the child to use crutches is an important nursing intervention for any child with lower extremity immobilization so that the child can maintain mobility (Fig. 44.6). Provide home care instructions to the family about cast care (Teaching Guidelines 44.1).

Assisting With Cast Removal

Children may be frightened by cast removal. Prepare the child using age-appropriate terminology:

- The cast cutter will make a loud noise (Fig. 44.7).
- The skin or extremity will not be injured (demonstrate by touching the cast cutter lightly to your palm).
- The child will feel warmth or vibration during cast removal.

Teaching Guidelines 44.2 gives instructions related to skin care after cast removal.

Caring for the Child in Traction

Nursing care of the child in any type of traction focuses not only on appropriate application and maintenance of traction but also on promoting normal growth and development and preventing complications (see Table 44.2). Apply skin traction over intact skin only so that the pull of the traction is effective. Prepare the skin with an appropriate adhesive before applying the traction tapes to ensure that the tapes adhere well, preventing skin friction. After application of the traction tapes, apply the elastic bandage or use the foam boot. Attach the traction spreader block and then apply the prescribed amount of weight via a rope attached to the spreader block. Ensure that the rope moves without obstruction and that the weights hang freely without touching the floor.

In skeletal traction, apply weight via ropes attached to the skeletal pins. The pin sites should be treated as surgical wounds (see section on pin site care). Protect the exposed ends of the pins to avoid injury. Whether skin or skeletal traction is used, be sure that constant and even traction is maintained.

FIGURE 44.6 Reinforce appropriate crutch walking for children with lower extremity immobilization.

TEACHING GUIDELINES 44.1

Home Cast Care

- For the first 48 hours, elevate the extremity above the level of the heart and apply cold therapy for 20 to 30 minutes, then off 1 hour, and repeat.
- Assess for swelling, and have the child wiggle the fingers or toes hourly.
- For itching inside the cast:
  - Never insert anything into the cast for the purposes of scratching.
  - Blow cool air in from a hair dryer set on the lowest setting.
  - Do not use lotions or powders.
- Check the skin at the cast edges daily for irritation.
- Protect the cast from wetness.
- Apply a plastic bag around cast and tape securely for bathing or showering.
- Call the physician if:
  - The casted extremity is cool to the touch.
  - The child cannot move the fingers or toes.
  - Severe pain occurs when the child attempts to move the fingers or toes.
  - Persistent numbness or tingling occurs.
  - Drainage or a foul smell comes from under the cast.
  - Severe itching occurs inside the cast.
  - The child runs a fever greater than 101.5° F for longer than 24 hours.
  - Skin edges are red and swollen or exhibit breakdown.
  - The cast gets wet or is cracked, split, or softened.

Modified from DiFazio, R., & Atkinson, R. (2005). Extremity fractures in children: When is it an emergency? *Journal of Pediatric Nursing, 20*(4), 298–304.

▶ *Take* NOTE!

Avoid sudden bumping or movement of the bed: this can disturb traction alignment and cause additional pain to the child as the weights are jostled.

FIGURE 44.7 The loud noise of the cast saw may frighten the child.

Preventing Complications

Refer to Nursing Care Plan 44.1 for interventions related to pain management and prevention of complications of immobility such as skin integrity impairment. To prevent contractures and atrophy that may result from disuse of muscles, ensure that unaffected extremities are exercised. Assist the child to exercise the unaffected joints and to use the unaffected extremity if this does not disrupt traction alignment. Promote use of a trapeze if not contraindicated to involve the child in repositioning and assist with movement. Encourage deep-breathing exercises to prevent the pulmonary complications of long-term immobilization.

TEACHING GUIDELINES 44.2

Skin Care After Cast Removal

- Brown, flaky skin is normal and occurs as dead skin and secretions accumulate under the cast.
- Soak with warm water daily.
- Wash with warm soapy water, avoiding excessive rubbing, which may traumatize the skin.
- Discourage the child from scratching the dry skin.
- Apply moisturizing lotion to relieve dry skin.
- Encourage activity to regain strength and motion of extremity.

Promote normal growth and development by:

- Placing age-appropriate toys within the child's reach
- Encouraging visits from friends
- Providing diversional activities such as drawing, coloring, or video games (Fig. 44.8)

▶ *Take NOTE!*

Ongoing, careful neurovascular assessments are critical in the child with a cast or in skeletal traction. Notify the physician immediately if these signs of compartment syndrome occur: extreme pain (out of proportion to the situation), pain with passive range of motion of digits, distal extremity pallor, inability to move digits, loss of pulses.

Caring for the Child With an External Fixator

In addition to routine neurovascular assessment, elevate the extremity to prevent swelling. The fixator may be moved by grasping the frame, as the fixator can tolerate ordinary movement. Encourage weight bearing as prescribed. Provide appropriate education to the child and family. Encourage the child to look at the apparatus.

Providing Pin Care

Whether pins are inserted for skeletal traction or as part of an external fixator (see section on fractures), keeping the pin sites clean is important to prevent infection. Perform pin site care according to institutional policy or the physician's orders. Cleaning of the pin sites prevents infection by promoting comfort and preventing healing skin from adhering to the metal pin. Notify the orthopedic surgeon if signs of pin site infection are present or if pin slippage occurs.

Thus far, attempts to obtain evidence supporting the various types of pin site care have been unsuccessful. Certain physicians prefer the site to be cleaned with normal saline; others choose a solution with antibacterial properties. Some institutions recommend removal of all crusts formed on the skin around the pin; others do not. The rationale for crust removal is to promote free drainage and prevent the surrounding skin from adhering to the pin. A keyhole dressing may be necessary around the pin if drainage is present. No matter which procedure is ordered or preferred, perform pin care as necessary to prevent infection at the pin site. The Ilizarov fixator uses wires that are thinner than ordinary pins, so simply cleansing by showering is usually sufficient to keep the pin site clean. If drainage is present, the skin around the wires can be cleansed with a dry gauze pad.

TABLE 44.2 Types of Traction and Nursing Implications

Type of Traction	Description	Nursing Implications
Bryant's traction 	Both legs are extended vertically, with child's weight serving as countertraction. Skin traction is applied to both legs. Used for infants with femur fracture or developmental dysplasia of the hip.	Maintain appropriate position. Ensure heels and ankles are free from pressure. Rewrap elastic bandages as ordered.
Russell's traction 	Skin traction for femur fracture, hip and knee contractures. Uses a knee sling. In split Russell's traction, a portion of the traction weight may be redistributed via a pulley from the sling to the head of the bed (used for femur fracture, Legg-Calvé-Perthes disease, slipped capital femoral epiphysis).	Wrap bandages from ankle to thigh on children less than age 2 years, from ankle to knee on children older than 2 years. Use a foot support to prevent foot drop. Ensure heel is free from bed. Assess popliteal region for skin breakdown from the sling. Mark leg to ensure proper replacement of sling.
Buck's traction 	Skin traction for hip and knee contractures, Legg-Calvé-Perthes disease, slipped capital femoral epiphysis. Traction force delivered in straight line.	Remove traction boot every 8 hours to assess skin. Leg may be slightly abducted.
Cervical skin traction 	Skin traction applied with a skin strap (head halter). Used for neck sprains/strains, torticollis, or nerve trauma.	Ensure that head halter or skin strap does not place pressure on ears or throat. Limit of 5 to 7 pounds weight.
Side-arm 90-90 	Skin traction for humerus fractures and injuries to the shoulder girdle. Used to treat fractures of the humerus and injuries in or around the shoulder girdle.	Maintain elbow flexed at 90 degrees. Fingers and hand may feel cool because of elevation. Child may turn to affected side only.

(continued)

TABLE 44.2 TYPES OF TRACTION AND NURSING IMPLICATIONS (continued)

Type of Traction	Description	Nursing Implications
Dunlop side-arm 00-90	Skeletal traction through an olecranon screw or pin in distal humerus. Lower arm is held in balanced suspension.	See side-arm 90-90. In addition, provide appropriate pin site care.
90-90 traction	For femur fracture reduction when skin traction is inadequate. Skeletal traction with force applied through pin in distal femur.	A foam boot may be used for suspension of the lower leg. Force of traction applied to femur via the pin. The amount of weight used is just enough to hold lower limb suspended.
Cervical skeletal tongs 	Tongs attached to skull via pins. Used with fractures or dislocations of the cervical or high thoracic vertebrae.	Assess frequently for increased pain, respiratory distress, and cranial nerve or brachial plexus injury. Place on Stryker frame or specially equipped bed to ease positioning without disruption of alignment.
Halo traction	Metal halo attached to skull via pins. Used for cervical or high thoracic vertebrae fracture or dislocation and for postoperative immobilization following cervical fusion.	Refer to nursing implications for cervical tongs. Tape small wrench to front of brace so that front panel can be quickly removed in an emergency. May become ambulatory in this type of traction; will be top-heavy so may need assistance with balance.
Balanced suspension traction 	Used for femur, hip, or tibial fracture. Thomas splint suspends the thigh while the Pearson attachment allows knee flexion and supports the leg below the knee.	Avoid pressure to popliteal area.

FIGURE 44.8 Provide age-appropriate diversional activities and schoolwork for children confined to bed in traction.

Congenital and Developmental Disorders

Congenital anomalies of the musculoskeletal system are usually readily identified at birth. Congenital structural anomalies involving the skeleton include pectus excavatum, pectus carinatum, limb deficiencies, polydactyly or syndactyly, metatarsus adductus, congenital clubfoot, and osteogenesis imperfecta. A developmental anomaly that may be diagnosed at birth or later in life is developmental dysplasia of the hip. A muscular condition, torticollis, most often presents as a congenital condition but may also develop after birth. Tibia vara is a developmental disorder affecting young children. Rarely, a developmental positional alteration such as genu varum, genu valgum, or pes planus will persist past the usual age of resolution or cause the child pain. If those situations occur, bracing, orthotics, or surgical correction may become necessary.

PECTUS EXCAVATUM

Pectus excavatum and pectus carinatum are anterior chest wall deformities. Pectus excavatum, a funnel-shaped chest, accounts for 87% of anterior chest wall deformities (Goretsky et al., 2004). A depression that sinks inward is apparent at the xiphoid process (Fig. 44.9). Pectus carinatum, a protuberance of the chest wall, accounts for only 5% of anterior chest wall deformities. The remainder are mixed deformities.

Pectus excavatum does not resolve as the child grows; rather, it progresses with growth. The chest depression may be minimal or marked. When the pectus is more pronounced, cardiac and pulmonary compression occurs. Symptoms of this compression most often present during puberty, when the pectus quickly worsens. Children may complain of shortness of breath, withdraw from physical activities, and have a poor body image.

Therapeutic Management

Therapeutic management of pectus excavatum involves surgical correction, preferably before puberty, when the

EVIDENCE-BASED PRACTICE 44.1
Pin Site Cleaning Methods and Infection Prevention

● Study

External fixation (metal pins) is used to immobilize bones while fractures heal. By the nature of pin insertion into the bone, pin sites place the child at risk for development of an infection. Numerous studies have been conducted to evaluate the effectiveness of pin site care. To date, pin site care is usually determined by physician or institution preference. The authors reviewed randomized controlled studies that evaluated the management of pin sites. The interventions reviewed included any type of cleaning method versus no cleaning, sterile versus non-sterile technique, use of massage, and whether or not a dressing was used.

▲ Findings

The results were inconclusive. No particular method of pin site care was determined to be statistically significant in reducing infection from orthopedic pins.

■ Nursing Implications

Despite the lack of clear insight from this study, it remains important for nurses to continue vigilance regarding pin site care. Ongoing assessment of pin sites for signs of infection and monitoring of the child's temperature are particularly important. Provide pin site care according to the physician's preference or institution's protocol. With the lack of conclusive evidence related to pin site care, nurses caring for pediatric orthopedic patients are in a prime position to develop and execute a well-designed research study related to pin site care.

Temple, J. & Santy, J. (2007). Pin site care for preventing infections associated with external bone fixators and pins. *The Cochrane Library 2007, 4.* Indianapolis: John Wiley & Sons.

FIGURE 44.9 Pectus excavatum: note the depression in the chest wall at the xiphoid process.

skeleton is more pliable. Various surgical techniques may be used and generally involve either the placement of a surgical steel bar or using a piece of bone in the rib cage to lift the depression. This discussion will focus on care of the child who undergoes surgical steel bar placement for pectus correction.

Nursing Assessment

Elicit the health history, noting progression of the defect and effects on the child's cardiopulmonary function. Note shortness of breath, exercise intolerance, or chest pain. Observe the child's chest for anterior wall deformity, noting depth and severity. Auscultate the lungs to determine the adequacy of aeration. X-rays, computed tomography (CT), or magnetic resonance imaging (MRI) may be used to determine the extent of the anomaly and compression of inner structures.

Nursing Management

Prepare the child preoperatively by allowing a tour of the surgical area and the pediatric intensive care unit. Introduce the child to the pain scale that will be used in the postoperative period.

Postoperatively, nursing management focuses on assessment, protection of the surgical site, and pain management. Auscultate lung sounds frequently to determine the adequacy of aeration and to monitor for development of the complication of pneumothorax. Assess for signs of wound infection that would necessitate removal of the curved bar. Do not allow the child to lie on either side and do not log-roll the child (these positions may disrupt the bar's position). Administer analgesics as needed either intravenously or via the epidural catheter. Teach families that the child will not be allowed to lie on his or her side at home for 4 weeks after the surgery to ensure that the band does not shift. Encourage aerobic activity at home after cleared by the surgeon (this will increase the child's vital capacity, previously hindered by the pectus). The bar will be removed 2 to 4 years after the initial placement.

LIMB DEFICIENCIES

Limb deficiencies, either complete absence of a limb or a portion of it or deformity, occur as the fetus is developing. These defects are attributed to an amniotic band constricting the limb, resulting in either incomplete development or amputation of the limb. Many children born with limb deformities also have developmental craniofacial abnormalities (Morrissy et al., 2006).

Therapeutic management is aimed at improving the child's functional ability. Physical therapy and occupational therapy may be helpful. Adaptive equipment such as a prosthesis may also be prescribed.

Nursing Assessment

Note the extent of limb deformity, providing an accurate description of the presence or absence of a portion of the arm or leg, or missing fingers or toes. Assess the child's ability to use the extremity as a helper (arms) or in ambulation (legs). Determine status of acquisition of developmental skills.

Nursing Management

Reinforce prescribed activities that are meant to improve the child's function. Provide activities in which the child is capable of participating. If the limb deficiency is significant, refer the infant to the local early intervention office as soon as possible after birth. Early intervention, available in all 50 states, is designed to promote development from birth to age 3 years. Absence of a limb or a significant portion of a limb will have a considerable impact on the child's ability to meet developmental milestones as expected.

POLYDACTYLY/SYNDACTYLY

Polydactyly is the presence of extra digits on the hand or foot (Fig. 44.10). It occurs equally in both genders and affects African-Americans more frequently than Caucasians. One third of the time, polydactyly occurs in

FIGURE 44.10 Note additional digits (toes) of polydactyly.

both the hand and foot (Gore & Spencer, 2004). It usually involves digits at the border of the hand or foot, near the fifth finger or toe. Syndactyly is webbing of the fingers and toes.

Treatment includes tying off the additional digit until it falls off or surgical removal of the digit. No treatment is usually required for syndactyly, though surgical repair is sometimes performed for cosmetic reasons.

Nursing Assessment

Inspect the hands and feet for the presence of extra digits. Note whether the additional digits are soft (without bone) or are full or partial digits with bone present. Note location of webbing.

Nursing Management

If the digit is tied off, observe for expected necrosis of tissue and eventually loss of the extra digit. When surgical removal is necessary, provide routine pre- and postoperative care as appropriate.

METATARSUS ADDUCTUS

Metatarsus adductus, a medial deviation of the forefoot, is one of the most common foot deformities of childhood (Fig. 44.11). It occurs as a result of *in utero* positioning. It occurs as often as once in every 100 live births (Hart et al., 2005). Type I and Type II are usually benign deformities, resolving spontaneously by the age of 3 years. Children with type III deformity usually require manipulation and serial casting, preferably before the age of 8 months. Surgical intervention is rarely needed.

Nursing Assessment

The deformity is usually noted at birth. Note inward deviation of the forefoot. The great and second toes might be separated. Determine forefoot flexibility. Range of motion of the ankle, hindfoot, and midfoot is normal in all

FIGURE 44.11 Metatarsus adductus: note medial deviation of the forefoot.

three types. Box 44.1 describes the three types based on flexibility of the forefoot.

Nursing Management

Nursing care for children with type I and II metatarsus adductus is aimed at education and reassurance of the parents. The nursing care for the child with type III is similar to that of the child with clubfoot (see below).

CONGENITAL CLUBFOOT

Congenital clubfoot (also termed congenital talipes equinovarus) is a congenital anomaly that occurs in one to two of 1,000 live births (Hart et al., 2005). Clubfoot consists of:

- Talipes varus (inversion of the heel)
- Talipes equinus (plantarflexion of the foot; the heel is raised and would not strike the ground in a standing position)
- Cavus (plantarflexion of the forefoot on the hindfoot)
- Forefoot adduction with supination (the forefoot is inverted and turned slightly upward)

BOX 44.1 Types of Metatarsus Adductus

- Type I: Forefoot is flexible past neutral actively and passively.
- Type II: Forefoot is flexible passively past neutral, but only to midline actively.
- Type III: Forefoot is rigid and does not correct to midline even with passive stretching.

FIGURE 44.12 Note inverted heel, ankle equinus, and forefoot adduction in this infant with bilateral clubfoot.

The foot resembles the head of a golf club (Fig. 44.12). Half of all cases occur bilaterally. Males are affected two and a half times more frequently than females. The exact etiology of clubfoot is unknown.

Clubfoot may be classified into four categories: postural, neurogenic, syndromic, and idiopathic. Postural clubfoot often resolves with a short series of manipulative casting. Neurogenic clubfoot occurs in infants with myelomeningocele. Clubfoot in association with other syndromes (syndromic) is often resistant to treatment. Idiopathic clubfoot occurs in otherwise normal healthy infants. The approach to treatment is similar regardless of the classification.

Therapeutic Management

The goal of therapeutic management of clubfoot is achievement of a functional foot; treatment starts as soon after birth as possible. Weekly manipulation with serial cast changes is performed; later, cast changes occur every 2 weeks. This approach is successful in about half of all cases. The other infants require corrective shoes or bracing; in some infants, surgical release of soft tissue may be necessary. Following surgery, the foot is immobilized with a cast for up to 12 weeks, and then ankle–foot orthoses or corrective shoes are used for several years.

Complications of clubfoot and its treatment include residual deformity, rocker-bottom foot, awkward gait, weight bearing on the lateral portion of the foot if uncorrected, and disturbance to the epiphysis.

Nursing Assessment

Note family history of foot deformities and obstetric history of breech position. Inspect the foot for position at rest. Perform active range of motion, noting inability to move foot into normal positioning at midline. X-rays are obtained to determine bony abnormality and note progress during treatment.

Nursing Management

Perform neurovascular assessment and cast care as for any disorder requiring casting. Provide emotional support, as treatment often begins in the newborn period and families may have a difficult time adjusting to the diagnosis and treatment required for their new baby. Teach families cast care and later the use of orthotics or braces as prescribed.

OSTEOGENESIS IMPERFECTA

Osteogenesis imperfecta is a genetic bone disorder that results in low bone mass, increased fragility of the bones, and other connective tissue problems such as joint hypermobility, resulting in instability of the joints that may further contribute to fracture occurrence. Dentinogenesis imperfecta may also occur: the tooth enamel wears easily and the teeth become discolored.

The disorder usually occurs as a result of a defect in the collagen type 1 gene, usually through an autosomal recessive or dominant inheritance pattern. The types of osteogenesis imperfecta range from mild to severe connective tissue and bone involvement (Table 44.3). In children with

TABLE 44.3 Classification of Osteogenesis Imperfecta

Classification	Characteristics
I	Common and mild Autosomal dominant Blue sclera Fragile bones, early fractures (by preschool age) Type A without dentinogenesis imperfecta, type B with dentinogenesis
II	Lethal in perinatal period Autosomal recessive Dark-blue sclera
III	Severe Autosomal recessive Normal sclera Fractures at birth with progressive deformity
IV	Moderately severe Autosomal dominant Normal sclera Fragile bones Type A without dentinogenesis imperfecta, type B with dentinogenesis

Zaleske, D. J. (2006). Metabolic and endocrine abnormalities. In R. T. Morrissy & S. L. Weinstein (Eds.), *Lovell & Winter's pediatric orthopaedics* (6th ed.). Philadelphia: Lippincott Williams & Wilkins.

moderate to severe disease, fractures are more likely to occur, and short stature is common. In addition to multiple fractures, additional complications include early hearing loss, acute and chronic pain, scoliosis, and respiratory problems.

▶ *Take* NOTE!

Blue sclera is not diagnostic of osteogenesis imperfecta, but it is a common finding. The sclerae of newborns tend to be bluish, progressing to white over the first few weeks of life. There are some individuals with blue sclerae who do not have osteogenesis imperfecta.

Therapeutic Management

The goal of medical and surgical management is to decrease the incidence of fractures and maintain mobility. Bisphosphonate administration is used for moderate to severe disease. Fracture care is often required. Physical therapy and occupational therapy prevent contractures and maximize mobility. Standing with bracing is encouraged. Lightweight splints or braces may allow the child to bear weight earlier. Severe cases may require surgical insertion of rods into the long bones.

Nursing Assessment

Elicit a health history, which may reveal a family history of osteogenesis imperfecta, a pattern of frequent fractures, or screaming associated with routine care and handling of the newborn. Inspect the eyes for sclerae that have a blue, purple, or gray tint. Note abnormalities of the primary teeth. Inspect skin for bruising and note joint hypermobility with active range of motion. Laboratory tests may include a skin biopsy (which reveals abnormalities in type 1 collagen) or DNA testing (locating the genetic mutation).

Nursing Management

Handle the child carefully and teach the family to avoid trauma (Teaching Guidelines 44.3). Refer families to the Osteogenesis Imperfecta Foundation (www.oif.org), which provides access to multiple resources as well as clinical trials. An excellent book for families of children with osteogenesis imperfecta is *Children with OI: Strategies to Enhance Performance* by H. L. Cintas and L. H. Gerber.

Encourage safe mobility. Reinforce physical and occupational therapists' recommendations for promotion of fine motor skills and independence in activities of daily living, as well as use of adaptive equipment and appropriate promotion of mobility. Adapted physical education is important to promote mobility and maintain bone and muscle mass. If the child is ambulatory, even with adaptive equipment use, walking is a good form of exercise. Swimming and water therapy are appropriate, allowing independent movement with little fracture risk.

TEACHING GUIDELINES 44.3

Preventing Injury in Children With Osteogenesis Imperfecta

- Never push or pull on an arm or leg.
- Do not bend an arm or leg into an awkward position.
- Lift a baby by placing one hand under the legs and buttocks and one hand under the shoulders, head, and neck.
- Do not lift a baby's legs by the ankles to change the diaper.
- Do not lift a baby or small child from under the armpits.
- Provide supported positioning.
- If fracture is suspected, handle the limb minimally.

▶ *Take* NOTE!

Use caution when inserting an intravenous line or taking a blood pressure measurement, as pressure on the arm or leg can lead to bruising and fractures.

DEVELOPMENTAL DYSPLASIA OF THE HIP

Developmental dysplasia of the hip (DDH) refers to abnormalities of the developing hip that include dislocation, subluxation, and dysplasia of the hip joint. In DDH, the femoral head has an abnormal relationship to the acetabulum. Frank dislocation of the hip may occur, in which there is no contact between the femoral head and acetabulum. Subluxation is a partial dislocation, meaning that the acetabulum is not fully seated within the hip joint. Dysplasia refers to an acetabulum that is shallow or sloping instead of cup-shaped. DDH may affect just one or both hips. The dysplastic hip may be provoked to subluxation or dislocated and then reduced again. DDH affects females eight times more often than males (Fig. 44.13).

Pathophysiology

While dislocation may occur during a growth period *in utero*, the laxity of the newborn's hip allows dislocation and relocation of the hip to occur. The hip can develop normally

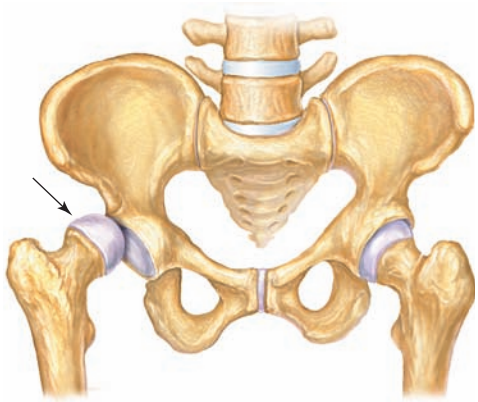


FIGURE 44.13 Developmental dysplasia of the hip.

only if the femoral head is appropriately and deeply seated within the acetabulum. If subluxation and periodic or continued dislocation occur, then structural changes in the hip's anatomy occur. Continued dysplasia of the hip leads to limited abduction of the hip and contracture of muscles. DDH is more common in females, probably because female hormones contribute to laxity of the ligaments. Mechanical factors such as breech positioning or the presence of oligohydramnios also contribute to the development of DDH. Genetic factors also play a role: there is an increased incidence of DDH among persons of Native American and Lapp descent, with very low rates among people of African or southern Chinese heritage. Complications of DDH include avascular necrosis of the femoral head, loss of range of motion, recurrently unstable hip, femoral nerve palsy, leg-length discrepancy, and early osteoarthritis.

Therapeutic Management

The goal of therapeutic management is to maintain the hip joint in reduction so that the femoral head and acetabulum can develop properly.

Treatment varies based upon the child's age and the severity of DDH. Infants younger than 6 months of age may be treated with a Pavlik harness, which reduces and stabilizes the hip by preventing hip extension and adduction. The Pavlik harness is successful in the treatment of DDH in the majority of infants less than 6 months of age if it is used on a full-time basis and applied properly (Weinstein, 2006). Children from 6 months to 2 years of age often require closed reduction. Skin or skeletal traction may be used first to gradually stretch the associated soft tissue structures. Closed reduction occurs under general anesthesia, with the hip being gently maneuvered back into the acetabulum. A spica cast worn for 12 weeks maintains reduction of the hip. After the cast is removed, the child must wear an abduction brace full-time (except for baths) for 2 months. Then the brace is worn at night and during naps until development of the acetabulum is normal. Children over 2 years of age or those who have failed to respond to prior treatment require an open surgical reduction followed by a period of casting (Weinstein, 2006).

Nursing Assessment

Nursing assessment of children with DDH includes obtaining a health history and inspecting, observing, and palpating for findings common to DDH.

Health History

Assess the health history for risk factors such as:

- Family history of DDH
- Female gender
- Oligohydramnios or breech birth
- Native American or Laplander descent
- Associated lower limb deformity or other congenital musculoskeletal deformity

Previously undiagnosed older children may complain of hip pain.

Physical Assessment

The physical examination for DDH includes inspection, observation, and palpation. Since DDH is a developmental process, ongoing screening assessments are required throughout at least the first several months of the infant's life.

Inspection and Observation

Ensure that the infant is on a flat surface and is relaxed. Note asymmetry of thigh or gluteal folds with the infant in a prone position. Document shortening of affected femur observed as limb-length discrepancy. Older children may exhibit **Trendelenburg gait**. Figure 44.14 illustrates these assessments.

Palpation

Note limited hip abduction when passive range of motion is performed. Abduction should ordinarily occur to 75 degrees and adduction to within 30 degrees with the infant's pelvis stabilized. Perform Barlow and Ortolani tests, noting a "clunk" as the femoral head dislocates or reduces back into the acetabulum. Force is not necessary when performing the Barlow and Ortolani maneuvers (see Fig. 44.14).

▶ *Take* NOTE!

A higher-pitched "click" may occur with flexion or extension of the hip. When assessing for DDH, do not confuse this benign, adventitial sound with a true "clunk."

Diagnostic Testing

Ultrasound of the hip allows for visualization of the femoral head and the outer edge of the acetabulum. Plain hip x-rays may be used in the infant or child over 6 months of age.

A. Assess for asymmetry of thigh and gluteal folds.

B. Assess for unequal knee height related to femur shortening.

C. Note limitation in hip abduction.

D. Positive Trendelenburg sign: note pelvis/hip drops when leg is raised.

E. Assess for "clunk" with the Ortolani maneuver.

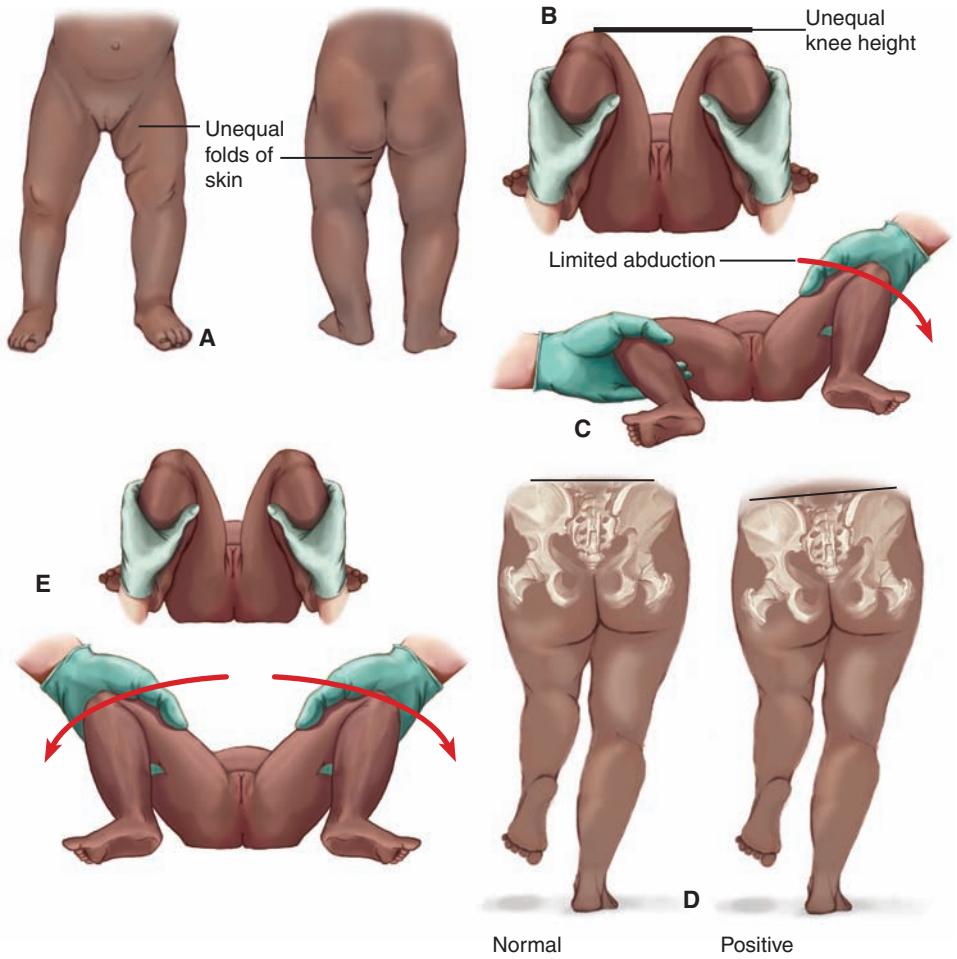

FIGURE 44.14 Assessment techniques for developmental dysplasia of the hip.

Nursing Management

Earlier recognition of hip dysplasia with earlier harness use results in better correction of the anomaly. Excellent assessment skills and reporting of any abnormal findings are critical. Initially, the infant will need to wear the Pavlik harness continuously (Fig. 44.15). The physician makes all appropriate adjustments to the harness when applied so that the hips are held in the optimal position for appropriate development. Teach parents use of the harness and assessment of the baby's skin. If started early, harness use usually continues for about 3 months (Teaching Guidelines 44.4). Breastfeeding can continue throughout the harness treatment period, but creative positioning of the infant may be needed.

For infants or children diagnosed later than 6 months of age or those who do not improve with harness use, surgical reduction may be performed after a period of traction. Postoperative casting followed by bracing or orthotic use is common. Caring for the child in the postoperative period is similar to care of any child in a cast. Pain management and monitoring for bleeding are priority activities. Teach families care of the cast at home.

TIBIA VARA (BLOUNT'S DISEASE)

Tibia vara (Blount's disease) is a developmental disorder affecting young children. The normal physiologic bowing or genu varum becomes more pronounced in the child with tibia vara. The cause of tibia vara is unknown, but it is considered to be a developmental disorder as it occurs most frequently in children who are early walkers. Most cases occur in African-Americans. In addition to early walking, obesity is also a risk factor. If left untreated, the growth plate of the upper tibia ceases bone production. Asymmetric growth at the knee then occurs and the bowing progresses. Severe degenerative arthritis of the knee is an additional long-term complication.

Therapeutic management is aimed at stopping the progression of the disease through bracing or surgical

FIGURE 44.15 Pavlik harness for treatment of developmental dysplasia of the hip.

treatment. Medical or surgical treatment should begin early, before 4 years of age.

Nursing Assessment

Elicit a health history and determine the age at which the child started walking. Assess growth parameters to determine whether the risk factor of obesity is present. Note significant bowing of the legs in standing and while ambulating (Fig. 44.16).

Nursing Management

Bracing may include a modified knee–ankle–foot orthosis that relieves the compression forces on the growth plate, allowing bone growth resumption and correction of bowlegs. To be successful, bracing must be continued for months to years and the brace must be worn 23 hours per day. Compliance is the most significant barrier to successful treatment. Parents have a difficult time forcing their toddler to stay in a brace that inhibits mobility for the bulk of the day (particularly a bilateral brace). Support parents by encouraging and praising their compliance with bracing. Teach parents to assess for potential skin impairment from brace rubbing.

When surgical treatment is required, the leg(s) will be immobilized in a long-leg bent knee or spica cast after the osteotomy is performed. Perform routine cast care. Refer to Nursing Care Plan 44.1 for additional interventions related to care of the immobilized child.

TEACHING GUIDELINES 44.4

Caring for a Child in a Pavlik Harness

- Do not adjust the straps without checking with the physician first.
- Until your physician instructs you to take the harness off for a period of time each day, it must be used continuously (for the first week or sometimes longer).
- Change your baby's diaper while in the harness.
- Place your baby to sleep on his or her back.
- Do not place clothes under the harness during the period of continuous use.
- Once the baby is permitted to be out of the harness for a short period, you may bathe your baby while the harness is off.
- Long knee socks and an undershirt are recommended to prevent rubbing of the skin against the brace.
- Note location of the markings on the straps for appropriate placement of the harness.
- Wash the harness with mild detergent by hand and air dry. If using the dryer, use *only* the air fluffing setting (no heat).

TORTICOLLIS

Torticollis is a painless muscular condition presenting in infants or in children with certain syndromes. Congenital muscular torticollis may result from *in utero* positioning or difficult birth. Preferential turning of the head to one side while in the supine position after birth may also lead to torticollis. Torticollis results from tightness of the sternocleidomastoid muscle, resulting in the infant's head being tilted to one side.

Medical treatment involves passive stretching exercises, which are effective in 90% of affected infants (Luther, 2002). Botulinum toxin injection has been used recently with success in cases of torticollis that have not improved with stretching exercises. Plagiocephaly may result from the continued pressure on the side of the skull to which the neck is turned.

FIGURE 44.16 Note extreme bowing of the legs in tibia vara.

Nursing Assessment

Note history of head tilt and infant's lack of desire to turn the head in the opposite direction. Observe the infant for wry-neck (tilting of the head to one side; Fig. 44.17). Note limited movement of the neck when passive range of motion is performed. Palpate the neck, noting a mass in the sternocleidomastoid muscle on the affected side. Examine the head for evidence of plagiocephaly.

Nursing Management

Teach parents gentle neck-stretching exercises to be performed several times a day. While immobilizing the shoulder on the affected side, gently sustain a side-to-side stretch toward the unaffected side, holding the stretch for 10 to 30 seconds. Repeat 10 to 15 times per session. Perform an ear-to-shoulder stretch in a similar fashion. To prevent the development of torticollis in the unaffected infant, positional plagiocephaly must be prevented. Prevent flatness of one side of the head by varying the baby's head position, and do not always turn the head to one side while in the infant seat or swing or lying supine. Refer families to the National Infant Torticollis Foundation (www.infant-torticollis.org), a parent support network.

FIGURE 44.17 Note wry-neck or head tilt in the infant with torticollis.

Acquired Disorders

Several acquired musculoskeletal disorders may affect children. Nutritional deficits or malabsorption of fats may lead to rickets. Slipped capital femoral epiphysis and Legg-Calvé-Perthes disease affect mainly school-age and adolescent boys. Osteomyelitis, septic arthritis, and toxic synovitis are common infectious musculoskeletal disorders. Spinal curvature may occur as a result of a neuromuscular disorder or idiopathically.

RICKETS

Rickets is a condition in which there is softening or weakening of the bones. Childhood rickets may occur as a result of nutritional deficiencies such as inadequate consumption of calcium or limited exposure to sunlight (required for adequate production of vitamin D). Rickets may also occur if the body cannot regulate calcium and phosphorus in the appropriate balance, such as in chronic renal disease. Gastrointestinal disorders in which fat absorption is altered (e.g., Crohn's disease and cystic fibrosis) may lead to rickets, as vitamin D is a fat-soluble vitamin. Vitamin D regulates calcium absorption from the small intestine and levels of calcium and phosphate in the bones. Calcium is primarily laid down in the bones of the fetus during the third trimester. Premature infants miss this period of calcium accumulation and also suffer from inadequate calcium intake in the neonatal period and often demonstrate rickets of prematurity. When calcium and phosphate levels in the blood are imbalanced, then calcium is released from the

bones into the blood, resulting in loss of the supportive bony matrix. Rickets is most likely to occur during periods of rapid growth.

Therapeutic Management

Treatment of rickets is aimed at correcting the calcium imbalance so that the skeleton may develop properly and without deformity. Calcium and phosphorus supplements are given, and some children also require vitamin D supplements. If rickets is not corrected while the child is still growing, permanent skeletal deformities and short stature may result.

▶ *Take* NOTE!

Children who do not receive adequate daily exposure to sunlight require supplementation with 5 micrograms of vitamin D per day.

Nursing Assessment

Obtain a health history, determining risk factors such as:

- Limited exposure to sunlight
- Strict vegetarian diet or lactose intolerance (either one without milk product ingestion)
- Exclusive breastfeeding by a mother who has a vitamin D deficiency
- Dark-pigmented skin
- Prematurity
- Malabsorptive gastrointestinal disorder
- Chronic renal disease

Note history of fractures or bone pain. Observe for dental deformities and bowlegs. Decreased muscle tone may also be present. Note low serum calcium and phosphate levels and high alkaline phosphatase levels. X-rays may show changes in the shape and structure of the bone.

Nursing Management

Administer calcium and phosphorus supplements at alternate times to promote proper absorption of both of these supplements. Encourage exposure to moderate amounts of sunlight and administer vitamin D supplements as prescribed. Teach families that good dietary sources of vitamin D are fish, liver, and processed milk.

SLIPPED CAPITAL FEMORAL EPIPHYSIS

Slipped capital femoral epiphysis (SCFE) is a condition in which the femoral head dislocates from the neck and shaft of the femur at the level of the epiphyseal plate. The epiphysis slips downward and backward. SCFE occurs most frequently in obese males, 9 to 16 years of age; it is more common in African-American boys than in Caucasians (Leung & Lemay, 2004). The exact cause is unknown, but it is thought that during the teenage growth spurt the femoral growth plate weakens and becomes less resistant to stressors. Hormonal alterations during this period may also play a role.

SCFE is classified based upon its severity and whether the slip is acute or chronic. Chronic SCFE may lead to shortening of the affected leg and thigh atrophy.

Therapeutic Management

Promptly refer the child with SCFE to an orthopedic surgeon, as early surgical intervention will decrease the risk of long-term deformity. The goals of therapeutic management are to prevent further slippage, minimize deformity, and avoid the complications of cartilage necrosis (chondrolysis) and avascular necrosis of the femoral head. Surgical intervention may include in situ pinning, in which a pin or screw is inserted percutaneously into the femoral head to hold it in place. Osteotomy may be used for more severe cases. Osteoarthritis may be a long-term complication of SCFE.

Nursing Assessment

Elicit a health history, determining the onset and extent of pain. In acute SCFE, the pain is usually sudden in onset and results in inability to bear weight. Chronic SCFE may present with an insidious onset of pain and limp. Note risk factors of age 9 to 16 years, African-American race, and obesity. Observe ambulation, noting Trendelenburg gait. Assess for pain that is in the hip or that is referred to the groin, medial thigh, or knee. Note decreased range of motion in the affected hip with external rotation. X-rays will be obtained to confirm the diagnosis (anteroposterior and lateral frog-leg views of hips). Bone scan can rule out avascular necrosis, and CT scan helps define the extent of slippage.

▶ *Take* NOTE!

Do not attempt to perform passive range of motion to determine the extent of limitation in the child with SCFE; this may cause worsening of the condition.

Nursing Management

Enforce bed rest and activity restriction. If traction is used for a period before surgery, perform routine traction care and neurovascular assessments. Assess pain and administer analgesics as needed. After in situ pinning, assist the

child with crutch walking. Teach the family that weight bearing is usually resumed about a week after the surgery and that the pin will be removed later. Prolonged immobility may isolate the adolescent from usual peer interactions, so encourage phone calls and visits with friends. Provide books, games, electronic devices, and magazines for distraction during the period of immobility. Provide family support.

LEGG-CALVÉ-PERTHES DISEASE

Legg-Calvé-Perthes disease is a self-limiting condition that involves avascular necrosis of the femoral head. It most often affects children aged 4 to 8 years, but can occur as early as 18 months, until skeletal maturity (Hoffmeister, 2008). The disease affects girls much less frequently. The etiology is unknown, but the interruption of the blood supply to the femoral head results in bone death, and the spherical shape of the femoral head may be lost. Swelling of the soft tissues around the hip may occur. As new blood vessels develop, the area is supplied with circulation, allowing bone resorption and deposition to take place. During this period of revascularization, which takes 18 to 24 months, the bone is soft and more likely to fracture. Over time, the femoral head reforms.

Therapeutic Management

The goal of therapeutic management is to maintain normal femoral head shape and to restore appropriate motion. Treatment of Legg-Calvé-Perthes disease includes anti-inflammatory medication to decrease muscle spasms around the hip joint and to relieve pain. Activity limitation may be prescribed, and sometimes bracing is recommended to contain the femoral head. Serial x-ray follow-up determines progress of the disease. If surgery becomes warranted, then osteotomy may be performed. Complications include joint deformity, early degenerative joint disease, persistent pain, loss of hip motion or function, and gait disturbance.

Nursing Assessment

Explore the health history for short stature, delayed bone maturation, or a family history of Legg-Calvé-Perthes disease. Note painless limp, which may be intermittent over a period of months. Mild hip pain may result and may be referred to the knee or the thigh. Pain may be aggravated by exercise. Observe the child walking and note Trendelenburg gait. Perform range of motion, noting internal rotation of the hip and limited abduction. Muscle spasm may result with hip extension and rotation. Hip x-rays are obtained to evaluate the extent of epiphyseal involvement. MRI or bone scan may also be used to differentiate Legg-Calvé-Perthes disease from other disorders.

Nursing Management

Nursing care of Legg-Calvé-Perthes disease is highly variable and depends on the stage of the disease and its severity. Administer anti-inflammatory medications, noting their effect on pain. If activities are restricted, exercise the unaffected body parts. Assist families with use of the brace if prescribed. The brace may be wiped with a damp cloth if it becomes dirty. Some children will be prescribed no treatment other than avoidance of contact or high-impact sports. Swimming and bicycle riding help to maintain range of motion with little risk. If mobility equipment is needed, educate the child and family on its use. If osteotomy is performed, provide routine postoperative care, with education and support of the child and family.

OSTEOMYELITIS

Osteomyelitis is a bacterial infection of the bone and soft tissue surrounding the bone. The long bone metaphysis is the most common location, with *Staphylococcus aureus* being the most common infecting organism (Eilert, 2007). Additional causes in infants include group B streptococcus and *Escherichia coli*; in children, *Streptococcus pyogenes* and *Haemophilus influenzae* are also implicated. Children usually present for evaluation within a few days to a week of onset of symptoms, though some may present later.

Osteomyelitis is acquired hematogenously. Bacteria from the bloodstream mainly invade the most rapidly growing portion of the bone. The invading bacteria trigger an inflammatory response, formation of pus and edema, and vascular congestion. Small blood vessels thrombose and the infection extends into the metaphyseal marrow cavity. As the infection progresses, the inflammation extends throughout the bone and blood supply is disrupted, resulting in death of the bone tissues (Fig. 44.18).

Therapeutic Management

Treatment includes a 4- to 6-week course of antibiotics. Some children may receive 1 to 2 weeks of intravenous antibiotics and then be switched to oral antibiotics for the remainder of the course. Surgical débridement is rarely necessary. Early treatment may prevent the complications of bone destruction, fracture, and growth arrest. Additional complications include recurrent infection, septic arthritis, and systemic infection.

Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1459. Assessment findings pertinent to osteomyelitis are discussed here. Explore the health

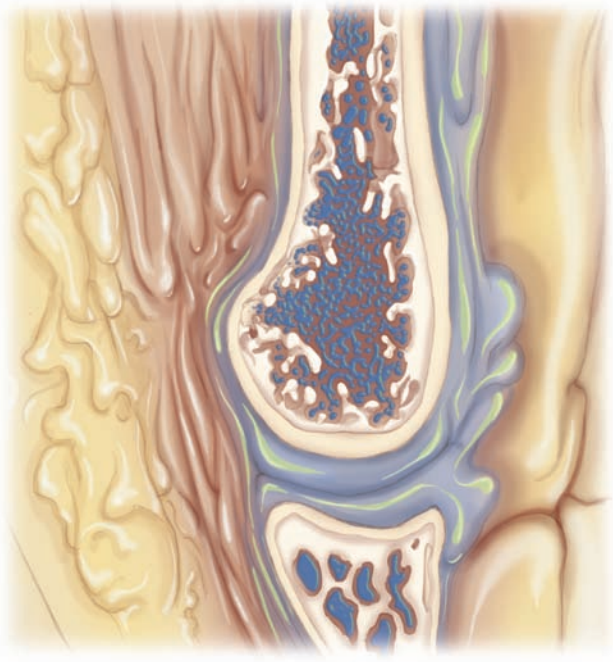

FIGURE 44.18 In osteomyelitis, bacterial invasion leads to infection within the bone.

history for risk factors and symptoms. Risk factors include impetigo, infected varicella lesions, furunculosis, infected burns, and prolonged intravenous line use. Note history of irritability, lethargy, possible fever, and onset of pain or change in activity level. The child usually refuses to walk and demonstrates decreased range of motion in the affected extremity. Inspect the affected extremity for swelling. Palpate for local warmth and tenderness. Note point tenderness over affected bone.

Laboratory and diagnostic testing may reveal:

- Elevated white blood cell count, erythrocyte sedimentation rate, and C-reactive protein level
- Positive blood cultures
- Deep soft tissue swelling on x-ray
- Changes on ultrasound or CT scan

Nursing Management

Nursing management of the child with osteomyelitis focuses on assessment, pain management, and maintenance of intravenous access for administration of antibiotics. Individualize care based on the child's and family's response to the illness; see Nursing Care Plan Overview 44.1. Maintain bed rest initially to prevent injury and promote comfort. Administer antipyretics as ordered if the child is febrile in the initial stage of the illness. Encourage use of unaffected extremities by providing developmentally appropriate toys and games. Instruct child and family on safe and proper use of crutches or walker if prescribed. Some children will be discharged home on intravenous antibiotics, while others will finish an oral antibiotic course. Teach parents proper administration of medications and maintenance of a peripherally inserted central catheter or central line at home if the child is finishing the antibiotic course intravenously.

SEPTIC ARTHRITIS

Acute septic arthritis is a condition in which bacteria invade the joint space, most often the hip. It usually occurs in children less than 10 years old, with 3- to 7-year-olds being most frequently affected. Bacteria gain access to the joint in one of three ways:

- Directly from a puncture of the joint or via venipuncture or wound infection
- Seeding from a distal infection site (e.g., otitis media or respiratory infection)
- Compression of the joint capsule from adjacent osteomyelitis

S. aureus, *H. influenzae* type B, and various streptococci are the most commonly responsible organisms. Sepsis of the hip joint may cause avascular necrosis of the femoral head due to pressure on blood vessels and cartilage within the joint space. Septic arthritis is considered a medical emergency, as this destruction may occur within just a few days. Additional complications of septic arthritis include permanent deformity, leg-length discrepancy, and long-term decreased range of motion and disability.

The goals of treatment of septic arthritis are to prevent destruction of the joint cartilage and maintain function, motion, and strength. Septic arthritis is treated rapidly with joint aspiration or arthrotomy, followed by intravenous antibiotic therapy while in the hospital and oral antibiotics at home.

Nursing Assessment

Note history of predisposing factors such as respiratory infection or otitis media, skin or soft tissue infections, or, in the neonate, traumatic puncture wounds and femoral venipunctures. The history is usually significant for sudden onset of fever and moderate to severe pain.

Upon physical examination, the infant or child appears ill. Note extent of fever, refusal to bear weight or straighten the hip, and limited range of motion (the child usually maintains the joint in flexion and will not allow the leg to be straightened). Palpate the affected joint for warmth and swelling.

Laboratory findings may include:

- White blood cell count normal or elevated with elevated neutrophil counts
- Elevated erythrocyte sedimentation rate and C-reactive protein levels

- Fluid from joint aspiration demonstrates elevated white blood cell count; culture determines responsible organism.
- Joint x-ray may show subtle soft tissue changes or increase in the joint space.
- Positive blood culture for the causative organism (15% of cases)

Nursing Management

Refer to Nursing Care Plan Overview 44.1 for interventions related to musculoskeletal disorders. Assess aspiration wound for signs of infection. Monitor vital signs for resolution of fever. Pain management with ibuprofen or acetaminophen will be sufficient for some children; others may initially require codeine or morphine. Assess the affected joint for decrease in swelling, increasing range of motion, and decreasing or absent pain. The child may be discharged after 72 hours of intravenous antibiotics following joint aspiration if he or she is improving and can tolerate oral antibiotics. At discharge, if the child cannot ambulate, physical therapy may be consulted for short-term use of crutches or a wheelchair. Teach families how to assess for signs and symptoms of wound infection, how to administer oral antibiotics and pain medication, and how to assist their child with crutch walking.

TRANSIENT SYNOVITIS OF THE HIP

Transient synovitis of the hip (also termed toxic synovitis) is the most common cause of hip pain in children (Eilert, 2007). It occurs in children as young as 9 months of age through adolescence, most commonly affecting children 3 to 8 years old. Boys are affected twice as often as girls and African-Americans exhibit the lowest incidence. The exact cause is unclear, but it is thought to be associated with recent or active infection or with trauma. A self-limiting disease, most cases resolve within a week, but it may last as long as 4 weeks. Therapeutic management involves nonsteroidal anti-inflammatory medications and bed rest to relieve weight bearing on the affected hip joint.

Nursing Assessment

Explore the health history for risk factors such as antecedent trauma, concurrent or recent upper respiratory tract infection, pharyngitis, or otitis media. Note sudden acute onset of moderate to severe pain of one hip. Sometimes pain is referred to the anterior thigh or knee. Pain is usually the worst upon arising in the morning, and the child refuses to walk, with pain decreasing throughout the day. Temperature will be normal or low-grade (<38°C). Observe for a limp or for refusal to bear weight. Observe position of the affected hip: it will be held in a flexed and externally rotated position. Note restricted range of motion for abduction and internal rotation.

Nursing Management

Nursing care focuses on educating the family. Parents are very concerned when their child refuses to walk, and they will need significant support and reassurance.

Scoliosis

Scoliosis is a lateral curvature of the spine that exceeds 10 degrees. It may be congenital, associated with other disorders, or idiopathic. Table 44.4 explains the types of scoliosis. Idiopathic scoliosis accounts for 65% of all cases of scoliosis, with the majority of those occurring during adolescence (Zak, 2005). Hence, this discussion will focus on adolescent idiopathic scoliosis. The etiology of idiopathic scoliosis is not known, but genetic factors, growth abnormalities, and bone, muscle, disk, or central nervous system disorders may contribute to its development. Early screening and detection of scoliosis result in improved outcomes.

Pathophysiology

In the rapidly growing adolescent, the involved vertebrae rotate around a vertical axis, resulting in lateral curvature. The vertebrae rotate to the convex side of curve, with the spinous processes rotating toward the concave side. Wedge-shaped vertebral bodies and disks develop because growth is suppressed on the concave side of the curve (Newton & Wenger, 2006). As the curve progresses, the shape of the thoracic cage changes and respiratory and cardiovascular compromise may occur (the main complications of severe scoliosis).

TABLE 44.4 TYPES OF SCOLIOSIS

Type	Associated Factors
Idiopathic	Unknown cause Infantile: occurs in the first 3 years of life Juvenile: diagnosed between age 4 and 10 years, or prior to adolescence Adolescent: age 11 to 17 years
Neuromuscular	Associated with neurologic or muscular disease such as cerebral palsy, myelomeningocele, spinal cord tumors, spinal muscular atrophy
Myopathic	Associated with certain types of muscular dystrophy
Congenital	Results from anomalous vertebral development

BOX 44.2 Types of Braces Used to Treat Scoliosis

- Underarm (Boston, Wilmington): less conspicuous, no visible neckpiece
- Milwaukee: traditional standard, has a visible neckpiece
- Nighttime bending (Charleston): creates a curve so severe that walking is not possible, so can be worn only at night

Therapeutic Management

Treatment of scoliosis is aimed at preventing progression of the curve and decreasing the impact on pulmonary and cardiac function. Treatment is based on the age of the child, expected future growth, and severity of the curve. Observation with serial examinations and spine x-rays is used to monitor curve progression. For curves of 20 to 50 degrees, bracing may be sufficient to decrease progression of the curve. Box 44.2 describes types of scoliosis braces and Figure 44.19 shows examples. The choice of brace will depend on the location and severity of the curve. Some curves will progress despite appropriate bracing and compliance.

Surgical correction is often required for curves greater than 45 degrees; it is achieved with rod placement and bone grafting. Partial spinal fusion accompanies many of the corrective surgeries. Multiple surgical approaches and techniques exist for fusion and rod placement. The surgical approach may be anterior, posterior, or both. Traditional rod placement (Harrington rod) involved a single rod fused to the vertebrae, resulting in curve correction but also a flat-backed appearance. Newer rod instrumentations allow for scoliosis curve correction with maintenance of normal back curvature. The rods are shorter, and several are wired or grafted to the appropriate vertebrae to achieve correction. Figure 44.20 shows one example of surgical rod instrumentation.

Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1459. Assessment findings pertinent to scoliosis are discussed below.

Health History

Determine why the child is presenting for evaluation of scoliosis. Commonly the child or adolescent will not report back pain, as only mild discomfort is associated with idiopathic scoliosis until the curve becomes severe. Often the family recognizes asymmetry in the hips or shoulders or the child is screened for scoliosis at school and determined to be at risk. Explore the client's current and past medical history for risk factors such as:

- Family history of scoliosis
- Recent growth spurt
- Physical changes related to puberty

Determine the age of development of secondary sex characteristics and the age of menarche, as these signs of pubertal development indicate the expected velocity and length of remaining growth.

Physical Examination

The physical assessment of a child with possible or actual scoliosis involves mainly inspection and observation.

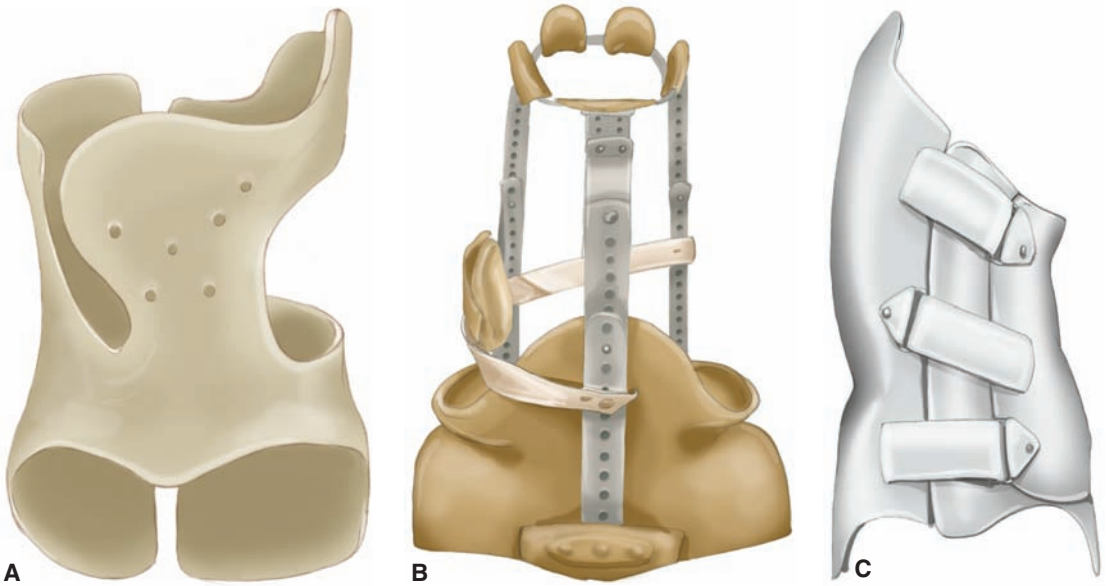

FIGURE 44.19 (**A**) Boston brace. (**B**) Milwaukee brace. (**C**) Nighttime bending brace.

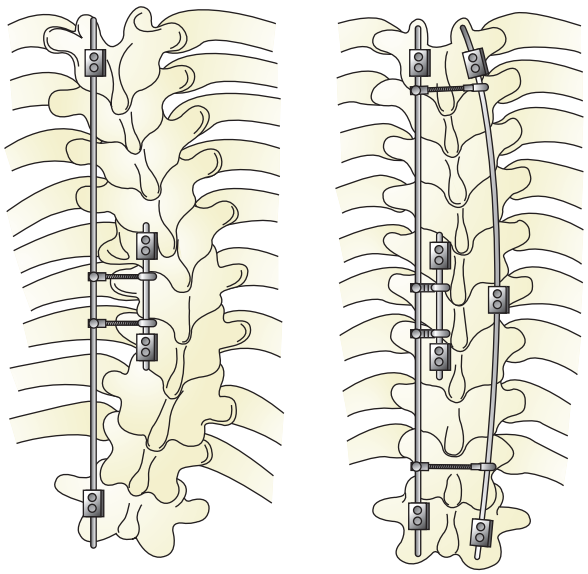

FIGURE 44.20 Rods are fused to the vertebrae and connected to a distracting rod to rotate the vertebral column (Cotrel-Dubousset method is shown).

Auscultate the heart and lungs to determine compromise related to severe curvature.

Observe the child at rest, sitting, and standing for evidence of poor posture. Inspect the child's back in a standing position. Note asymmetries such as shoulder elevation, prominence of one scapula, uneven curve at the waistline, or a rib hump on one side. Measure shoulder levels from the floor to the acromioclavicular joints. Note the difference between the height of the high and low shoulder in centimeters. Measure heights of anterior and posterior iliac spines and note the difference in centimeters. View the patient from the side, noting abnormalities in the spinal curve. With the child bending forward, arms hanging freely, note asymmetry of the back (pronounced hump on one side). Figure 44.21 shows scoliosis noted upon visual inspection. Note leg-length discrepancy if present. During the neurologic examination, balance, motor strength, sensation, and reflexes should all be normal.

Laboratory and Diagnostic Tests

Full-spine x-rays are necessary to determine the degree of curvature. The radiologist will determine the extent of the curve based on specific formulas and techniques of measurement.

Nursing Management

Nursing Care Plan 44.1 lists general interventions; nursing care should be tailored based on the adolescent's response to the disease and its treatment. Additional nursing interventions specific to scoliosis are discussed here.

Encouraging Compliance With Bracing

Bracing is intended to prevent progression of the curve but does not correct the current curve. Although modern braces display an improved appearance, with no visible neckpiece, and can be worn under clothes, many adolescents are not compliant with brace wear. The brace must be worn 23 hours per day to prevent curve progression. Many factors may contribute to noncompliance, including the discomfort associated with brace

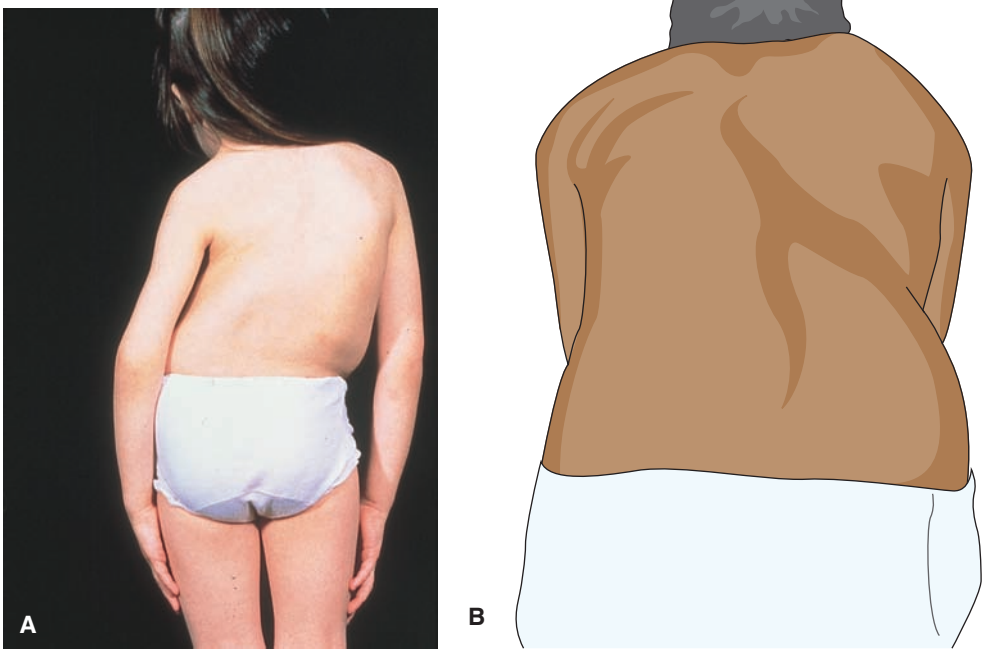

FIGURE 44.21 (**A**) Note right shoulder, scapula, and hip elevation as well as discrepancy in waist curvature. (**B**) Note right upper back hump.

wear such as pain, heat, and poor fit. The family environment may not be conducive to compliance with brace wear, and teenagers are very concerned about body image.

Inspect the skin for evidence of rubbing by the brace that may impair skin integrity. Teach families appropriate skin care and recommend they check the brace daily for fit and breakage. Encourage the teen to shower during the 1 hour per day that the brace is off and to ensure that the skin is clean and dry before putting the brace back on. Wearing a cotton T-shirt under the brace may decrease some of the discomfort associated with brace wear. Exercises to strengthen back muscles may prevent muscle atrophy from prolonged bracing and maintain spine flexibility.

Promoting Positive Body Image

Encourage the teen to express his or her feelings or concerns about wearing the brace. Give the teen ways to explain scoliosis and its treatment to his or her peers. Wearing stylish baggy clothes may help the teen to conceal the brace if desired. Refer teens and their families to the National Scoliosis Foundation (www.scoliosis.org) for additional support.

Providing Preoperative Care

If the curve progresses despite bracing or causes pulmonary or cardiac compromise, surgical intervention will be warranted. In the preoperative period, teach the teen the importance of turning, coughing, and deep breathing in the postoperative period. Explain the tubes and lines that will be present immediately after the surgery. Review positioning guidelines: back flexion or extension will not be allowed. Introduce the child to the patient-controlled analgesia pump and explain pain scales. There is a high risk for significant blood loss with spinal fusion and instrumentation, so if possible arrange for preoperative autologous blood donation.

Providing Postoperative Care

The goal of nursing management in the postoperative period after spinal fusion with or without instrumentation is to avoid complications. Perform neurovascular checks with each set of vital signs. When turning the child, use the log-roll technique to avoid flexion of the back (Fig. 44.22). Administer prophylactic intravenous antibiotics if ordered. Assess for drainage from the operative site and for excess blood loss via the Hemovac or other drainage tube. Maintain Foley patency, as the child will be confined to bed for the first couple of days. Maintain strict recording of fluid intake and output. Administer transfusions of packed red blood cells if ordered. Ambulation, once ordered, should be done slowly to avoid orthostatic hypotension. Assist the family with arrangements to continue the teen's school work while hospitalized and/or arrange for home tutoring during the several-week recovery period.

FIGURE 44.22 Log-roll the postoperative spinal fusion patient to prevent spine flexion.

▶ ***Consider*** *THIS!*

Angela Hernandez, a 15-year-old girl, is being seen in the clinic after she was found to be at high risk for scoliosis during a school screening. Upon assessment the nurse notes asymmetry of the hips, with shoulder elevation and prominence of one scapula. She is visibly upset and wants to know what caused this and what can be done. How would you address her concerns?

Angela's plan of care will include wearing of a brace. What education will be necessary and how can you promote compliance?

Describe nursing care for Angela if surgical correction is necessary.

Injuries

Injuries throughout childhood are inevitable. Trauma often occurs as a result of motor vehicle injury. The bulk of trauma resulting from physical activity or sports in children is due to running, skateboarding, and climbing trees. Only about one third of sports injuries in children occur during organized sports; the rest occur in physical education class or non-organized sports (Busch, 2006). Younger children tend to suffer contusions, sprains, and simple upper extremity fractures; adolescents more frequently experience lower-extremity trauma. As the number of children participating in youth sports increases and the intensity of training and the level of competition also increase, the incidence of injury is also likely to increase.

Many types of musculoskeletal injuries exist. This discussion will focus on fractures, sprains, overuse syndromes, and dislocated radial head.

▶ Take NOTE!

Fracture in the newborn or infant should raise a high index of suspicion for abuse, as fractures are very unusual in children who cannot yet walk.

FRACTURE

Fractures occur frequently in children and adolescents; 40% of boys and 25% of girls will suffer a fracture by age 16 years. About 50% of fractures occur in the distal forearm and hand. Greenstick and buckle fractures account for about half of pediatric fractures, and only about 20% of childhood fractures require reduction (Price et al., 2006).

▶ Take NOTE!

Do not attempt to straighten or manipulate an injured limb.

Pathophysiology

Fractures result most frequently from accidental trauma (DiFazio & Atkinson, 2005). Nonaccidental trauma (child abuse) and other disease processes are the other causes of fractures. The growth plate is the most vulnerable portion of the child's bone and is frequently the site of injury. The Salter-Harris classification system is used to describe fractures involving the growth plate (Table 44.5). The thicker, more elastic periosteum in children yields to the force encountered with trauma, resulting more frequently in nondisplaced fractures in children. The increased vascularity and decreased mineral content make the child's bones more flexible. Plastic or bowing deformities and buckle and greenstick fractures are the result. Complete fractures do occur in children, but they tend to be more stable than in the adult, resulting in improved healing and function. Spiral, pelvic, and hip fractures are rare in children. Table 44.6 explains common types of fractures in children.

Plastic deformity and Salter-Harris type IV fractures may result in an angular deformity. Though healing of fractures is usually quick and without incident in children, delayed union, nonunion, or malunion can occur. Additional complications include infection, avascular necrosis, bone shortening from epiphyseal arrest, vascular or nerve injuries, fat embolism, reflex sympathetic dystrophy, and compartment syndrome, which is an orthopedic emergency. Later in life, osteoarthritis may occur as a long-term complication from childhood fracture.

▶ Take NOTE!

Spiral femur fractures and humerus fractures, particularly in the child less than 2 years of age, should always be thoroughly investigated to rule out the possibility of child abuse.

Therapeutic Management

The vast majority of childhood fractures would heal well with splinting only, but casting of these fractures is performed to provide further comfort to the child and to allow for increased activity while the fracture is healing. Displaced fractures require manual traction to align the bones, followed by casting. More severe fractures may require traction for a period of time, usually followed by casting. Severe or complicated fractures may alternatively require open reduction and internal fixation for healing to occur. Complex fractures are often treated with external fixation (Fig. 44.23).

▶ Take NOTE!

Significant swelling may occur initially after immobilization with a splint. Splinting and then delaying casting for a few days provides time for some of the swelling to subside, allowing for successful casting a few days after the injury.

Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to page 1459. Assessment findings pertinent to fractures are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Common signs and symptoms reported during the health history might include recent trauma or fall, complaint of pain, difficulty bearing weight, limp, or refusal to use an extremity. Young children often demonstrate sudden onset of irritability and refusal to bear weight. Ask about the mechanism of injury and obtain a description of the traumatic event. Be alert to inconsistencies between the history and the clinical picture or mechanism of injury, as such inconsistency may be an indicator of child abuse. Explore the patient's current and past medical history for risk factors such as:

- Rickets
- Renal osteodystrophy
- Osteogenesis imperfecta
- Participation in sports, particularly contact sports

TABLE 44.5 The Salter–Harris Classification System

Type	Description	Illustration
I	Fracture is through the physis, widening it.	II	Fracture is partially through the physis, extending into the metaphysis.	III	Fracture is partially through the epiphysis, extending into the epiphysis.	
IV	Fracture is through the metaphysis, physis, epiphysis.	
V	Crushing injury to the physis	
TABLE 44.6 Types of Fractures in Children

Fracture Type	Description	Illustration
Plastic or bowing deformity	Significant bending without breaking of the bone	Buckle fracture	Compression injury; the bone buckles rather than breaks	
Greenstick fracture	Incomplete fracture of the bone	
Complete fracture	Bone breaks into two pieces	

- Failure to use protective equipment as recommended for various physical activities and sports (e.g., wrist guards while rollerblading)

Physical Examination

Perform the physical examination of the child with a potential fracture carefully, so as not to cause further pain or trauma. The physical examination particular to fractures includes inspection, observation, and palpation.

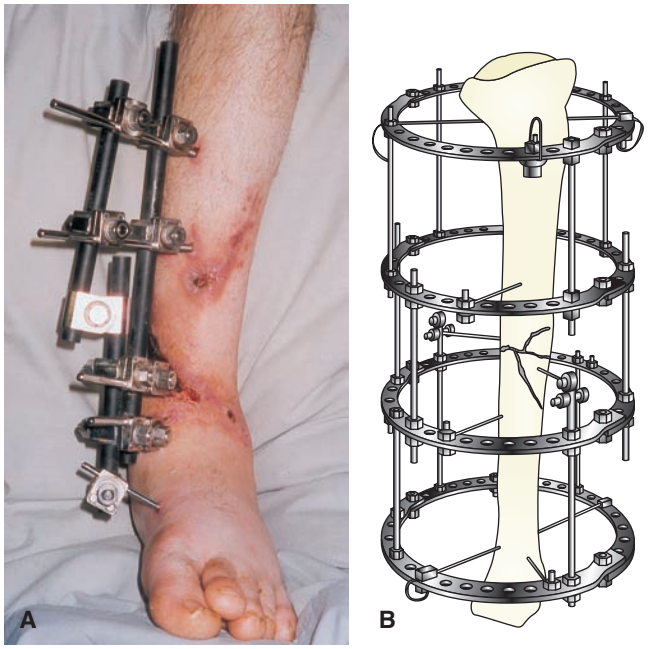

FIGURE 44.23 (**A**) External fixation is required for complicated fractures. (**B**) The Ilizarov fixator is a circular apparatus usually used for complicated lower extremity fractures. The pins are smaller in diameter, more like wires, than those used in other fixators.

Inspection and Observation

Inspect the skin for bruising, erythema, or swelling. Observe the extremities for deformity. Note neglect of an extremity or inability to bear weight. If ambulating, note any limp.

Palpation

Carefully palpate the joint or injured part. Distract the young child with a toy or activity while palpating. Note point tenderness, which is a reliable indicator of fracture in children. Assess neurovascular status, noting distal extremity temperature, spontaneous movement, sensation, numbness, capillary refill time, and quality of pulses. The neurovascular assessment is critical to providing a baseline so that any changes associated with compartment syndrome can be quickly identified.

Laboratory and Diagnostic Tests

Usually plain x-ray films are all that is required to identify a simple fracture. Complicated fractures that require surgical intervention may require further evaluation with CT or MRI.

Nursing Management

Immediately after the injury, immobilize the limb above and below the site of injury in the most comfortable position with a splint. Use cold therapy to reduce swelling in the first 48 hours after injury. Elevate the injured extremity above the level of the heart. Perform frequent neurovascular checks. Assess pain level and administer

pain medications as needed. Administer tetanus vaccine in the child with an open fracture if he or she has not received a tetanus booster within the past 5 years.

▶ *Take* NOTE!

Assess the injured, splinted, or casted extremity frequently for the "5 P's," which may indicate compartment syndrome: pain (increased out of proportion), pulselessness, pallor, paresthesia, paralysis. Report these findings immediately.

Providing Family Education

Unless bed rest is prescribed, children with upper extremity casts and "walking" leg casts can resume increased levels of activity as the pain subsides. Children who require crutches while in a cast may return to school, but those in spica casts will be at home for several weeks. Providing distraction and finding ways to keep up with school work are important. Families must also learn to care for the cast (see Teaching Guidelines 44.1).

Preventing Fractures

Discourage risky behavior such as climbing trees and performing tricks on bicycles. Provide appropriate supervision, particularly with outdoor activity. Encourage appropriate use of protective equipment, such as wrist guards with rollerblading and shin guards with soccer. Ensure that playground equipment is in good working order and intact; there should not be protruding screws or unbalanced portions of equipment, which may increase the risk for falling.

SPRAINS

Sprains result from a twisting or turning motion of the affected body part. The tendons and ligaments stretch excessively and may tear slightly. They may occur at any joint, but the most common are ankle and knee sprains. Therapeutic management of sprains includes rest, ice, compression, and elevation (RICE). On initial evaluation, sprains need to be differentiated from torn ligaments and meniscal tears, as those conditions are more serious and may require surgical intervention.

Nursing Assessment

Elicit a health history, determining the mechanism of injury (whether it occurred during sports or simply a misstep or fall). Determine what treatment the family has used so far. Inspect the affected body part for edema, which is frequently present, and bruising, which sometimes occurs. Note limp or inability to bear weight. Do not attempt to perform passive range of motion on the affected body part. Assess neurovascular status distal to the injury (usually normal).

Nursing Management

Instruct the child and family in appropriate treatment of sprains, which includes:

- Rest: limit activity.
- Ice: apply cold packs for 20 to 30 minutes, remove for 1 hour, and repeat (for the first 24 to 48 hours).
- Compression: apply an Ace wrap or other elastic bandage or brace; check skin for alterations when rewrapping.
- Elevation: elevate the injured extremity above the level of the heart to decrease swelling (Fig. 44.24).

The child may require instruction in crutch walking as well. Teach families that to prevent sprains during sports, it is important for the child to perform appropriate stretching and warm-up activities.

▶ *Take* NOTE!

If the child's fingers or toes become increasingly swollen or discolored, remove the Ace wrap immediately.

OVERUSE SYNDROMES

The term "overuse syndrome" refers to a group of disorders that result from repeated force applied to normal tissue. The connective tissues fail in response to repetitive stress, leading to a small amount of tissue breakdown. They develop over the course of weeks to months. There is usually no identifiable injury associated with overuse syndromes. Pain is usually associated with the activity and worsens with continued participation in the activity. Table 44.7 gives details on several common overuse syndromes. Therapeutic management is aimed at reassurance, pain management, and limiting rather than eliminating activity.

Nursing Assessment

Elicit a health history to determine the extent of involvement in sports. Note onset of pain, duration, intensity, aggravating factors, and treatments used at home. Examine the painful part, noting findings similar to those noted for each syndrome in Table 44.7.

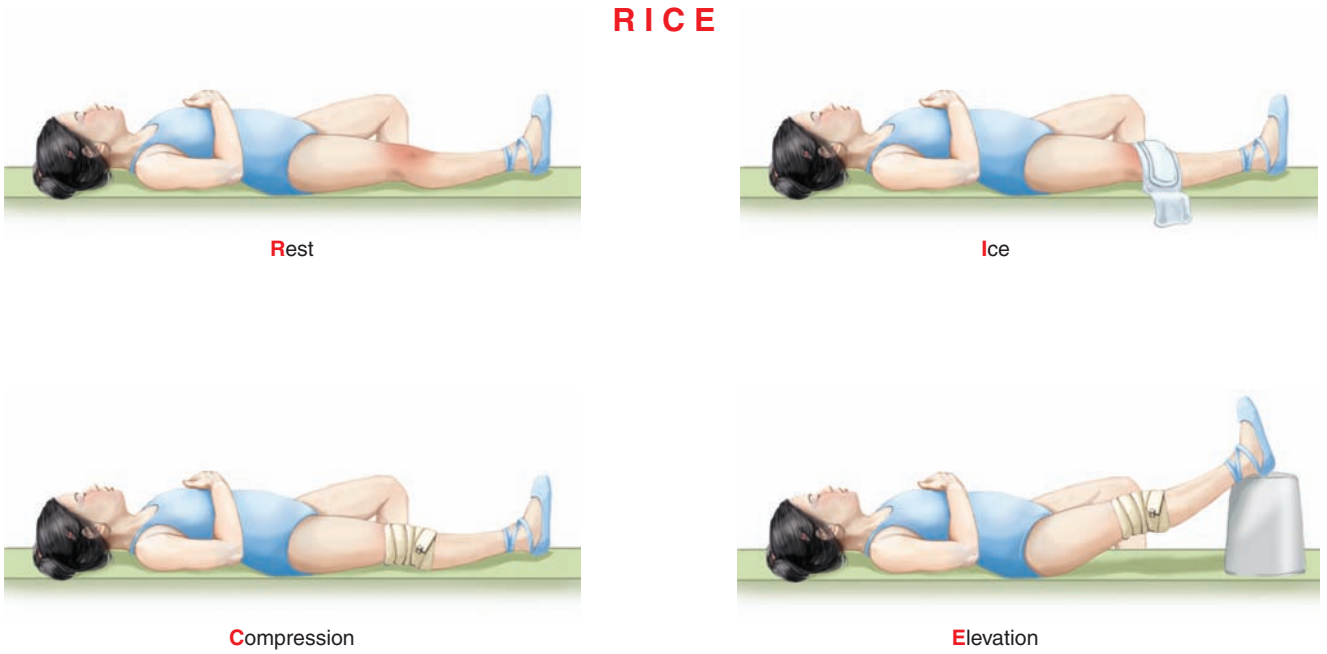

FIGURE 44.24 RICE (rest, ice, compression, elevation) is the appropriate treatment for sprains.

TABLE 44.7 OVERUSE DISORDERS

Disorder	Anatomic Area Affected	Most Commonly Occurs in	Symptoms
Osgood-Schlatter disease	Partial avulsion of the ossification center of the tibial tubercle	Active adolescents, most often boys. Most frequently during periods of rapid growth.	• Mild to moderate pain, activity-related. • Tibial tubercle is tender when palpated. • Painful swelling or prominence of the anterior portion of the tibial tubercle.
Epiphysiolysis of proximal humerus	Proximal humerus (widening of growth plate)	Occurs with rigorous upper extremity activity, such as baseball pitching	• Tenderness in the shoulder or proximal humerus. • Pain with active internal rotation. • Full shoulder range of motion continues.
Epiphysiolysis of distal radius	Distal radius (widening of growth plate)	Occurs with overuse of the distal radius, such as in gymnasts	• Wrist pain that worsens with activity.
Sever's disease (calcaneal apophysitis)	Calcaneus (heel)	Usually in 9- to 14-year-olds	• Pain over the posterior aspect of the calcaneus. • Limited active and passive dorsiflexion of foot.
Shin splints	Refers to a variety of overuse syndromes associated with the shin (stress fracture, tibial stress, muscular issues)	Occurs with activities that place repeated exertion on the lower leg, as in runners, ballerinas, elite soccer players	• Exercise-induced pain of the anterior aspect of the middle part of the lower leg. • May be sharp pain • Worsens with exercise • With stress fracture, may have a limp that worsens with activity.

Nursing Management

Initially, apply ice when pain is severe. Anti-inflammatory medications such as ibuprofen may be helpful. The child should limit exercise and participate in a different activity. After a few weeks, most overuse syndromes resolve; at that point, the athlete may resume the prior activity. Osgood-Schlatter disease is the exception and may require 12 to 18 months to resolve. Using pads or braces that are appropriate to the painful body part is also helpful. Supporting the arm with a sling may relieve stress on the proximal humerus when epiphysiolysis occurs. Heel cups used in athletic shoes help relieve stress on the heels associated with Sever's disease. To prevent overuse syndromes, encourage athletes to perform appropriate stretching exercises during a 20- to 30-minute warm-up period before each practice or game. Also encourage several weeks of conditioning training before the season begins.

▶ *Take NOTE!*

"Energy healing" such as therapeutic touch and Reiki may provide a nonpharmacologic adjunct to pain management for musculoskeletal injuries.

DISLOCATED RADIAL HEAD

Dislocation of the radial head ("nursemaid's elbow") occurs when a pulling motion on the arm causes the ligament surrounding the radial head to become entrapped within the joint. It usually occurs in children less than 7 years of age and is a common injury in children aged 1 to 4. To reduce the injury, the elbow is flexed to 90 degrees and then the forearm is fully and firmly supinated, causing the ligament to snap back into place. With appropriate reduction of the radial head, no complications result.

Nursing Assessment

The child will hold the arm slightly flexed at the side and refuse to move it. When the arm is still, the child apparently has no discomfort. Assess neurovascular status (intact).

Nursing Management

After treatment, usually hyperpronation to reduce the dislocation, assess the child's ability to use the arm without pain. Teach parents to avoid pulling up on the child's arm, particularly in an abrupt jerking fashion, to prevent recurrence.

Key Concepts

- The bones of the infant and young child are more flexible and have a thicker periosteum and more abundant blood supply than the adult's; as a result, bending occurs more frequently than breaking of the bone, and the fractured bone heals more quickly.
- The epiphysis of long bones is the growth center of the bones in children. Injury to this area may result in long-term extremity deformity.
- Rapid muscle growth in the adolescent years places the teenager at increased risk for injury compared with other age groups.
- Plain radiographs are usually sufficient for diagnosing injuries in children. If CT or MRI scans are required, the nurse may need to help the child stay calm and still during the procedure.
- Apply a pressure dressing following joint aspiration to prevent hematoma formation or fluid recollection.
- Perform frequent assessments of pain status and the effect of pain medication in the child with a musculoskeletal disorder.
- Diazepam (Valium) may be helpful in relieving muscle spasm associated with traction.
- Fractures may occur as a result of unintentional or intentional injury, or because the bones are fragile, as in rickets or osteogenesis imperfecta.
- Congenital or developmental disorders such as DDH or clubfoot require bracing or casting for correction and to prevent deformity later in life.
- Sprains, fractures, and overuse syndromes occur frequently in young athletes. Appropriate warm-up and stretching may help prevent some of these injuries.
- Assessment of neurovascular status is an essential component of care for a child with a neuromuscular disorder.
- To prevent complications after a spinal fusion for scoliosis correction, use the log-roll method for turning the child so that back flexion is avoided.
- Rest, ice, compression, and elevation is the appropriate treatment for sprains.
- Maintain traction and the appropriate amount of weight as ordered.
- The bulk of cast care occurs in the home. Teach the family of a child with a cast to perform neurovascular assessments, prevent the cast from getting wet, and care for the skin appropriately.
- Torticollis may be treated by teaching the family to perform daily neck muscle stretching exercises.
- Children with chronic disorders such as osteogenesis imperfecta may demonstrate slower or lesser growth than other children and may also be unable to participate in certain activities because of bone fragility.

Chapter Worksheet

Multiple Choice Questions

1. The nurse is evaluating a parent's understanding of treatment for torticollis. Which response best indicates that the parent understands the appropriate treatment?
   a. Encourages the infant to turn the head to the unaffected side.
   b. States that prone positioning for sleep will be needed.
   c. Places the infant on the affected side.
   d. Stretches the infant's neck to the opposite side and holds it for 5 seconds.
2. The nurse is providing patient education related to use of a brace that the orthopedic surgeon has ordered as treatment for idiopathic scoliosis in an adolescent girl. Which statement by the teen best indicates an understanding of appropriate use of the brace?
   a. "I can take my brace off only for special occasions."
   b. "I will take my brace off for only 1 hour per day, for showering."
   c. "I do not need to wear my brace at night while I am sleeping."
   d. "It is most important for me to wear my brace during the day, while I am upright."
3. The nurse is caring for orthopedic patients who are in the postoperative period following spinal fusion. What is the most appropriate activity to delegate to unlicensed assistive personnel?
   a. Ambulate the children twice daily to promote mobility.
   b. Encourage commode use to promote bowel function.
   c. Provide diversionary activities, as the children must stay flat on their backs.
   d. Assist with log-rolling the children every 2 hours.
4. The nurse is caring for a child with a fractured left femur who has been in skeletal traction for several days. Upon assessment, she notes that the left foot is pale, with a nonpalpable pedal pulse. What is the priority nursing intervention?
   a. Release the traction, as there may be too much weight on it.
   b. Nothing; alterations in circulation are expected with skeletal traction.
   c. Immediately notify the physician of this abnormal finding.
   d. Massage the foot immediately to increase circulation.

Critical Thinking Exercises

1. Develop a teaching plan for the family of an infant with developmental dysplasia of the hip or clubfoot.
2. Develop a discharge teaching plan for a 2-year-old who will be in a hip spica cast for 10 more weeks at home.
3. Devise a developmental/education plan for a child who will be confined to traction for 6 weeks. Choose a child in the clinical area whom you have cared for or choose a particular age group and develop the plan.

Study Activities

1. In the clinical setting, compare the growth and development of a child with osteogenesis imperfecta or rickets with that of typical healthy child. What differences or similarities do you find? What are the explanations for your findings?
2. Attend a pediatric orthopedic clinic or the local clinic of Children's Medical Services. Identify the role of the registered nurse in this setting.

CHAPTER 45

Nursing Care of the Child With an Integumentary Disorder

Eva Lopez, 1 year old, is brought to the clinic by her mother, who states, "Eva has dry patches of skin, her wrists bleed from her scratching, and she's having trouble sleeping at night."

KEY TERMS

annular
dermatitis
erythema
macule
papule
pruritus
scaling
vesicle

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Compare anatomic and physiologic differences of the integumentary system in infants and children versus adults.
2. Describe nursing care related to common laboratory and diagnostic tests used in the medical diagnosis of integumentary disorders in infants, children, and adolescents.
3. Distinguish integumentary disorders common in infants, children, and adolescents.
4. Identify appropriate nursing assessments and interventions related to pediatric integumentary disorders.
5. Develop an individualized nursing care plan for the child with an integumentary disorder.
6. Describe the psychosocial impact of a chronic integumentary disorder on children or adolescents.
7. Develop patient/family teaching plans for the child with an integumentary disorder.

Wow

To a nurse the child's skin is life's gift wrapping, but to the child the skin is the space suit for life.

Integumentary disorders occur often in children, and if they are severe or chronic they can have a significant impact on the child. Infants and children are exposed to a multitude of infectious microorganisms and allergens, and their skin is sometimes affected by these exposures. Some integumentary disorders are as mild and self-limited as a minor abrasion, while others, such as atopic dermatitis, are chronic. Any skin disorder that is severe or could become so can have a major impact on the child's physiologic or psychological status. Nurses who care for children need to be familiar with common skin disorders of infancy, childhood, and adolescence so they can effectively intervene with children and their families.

Variations in Pediatric Anatomy and Physiology

Skin is the largest organ of the body and serves to protect the underlying tissues from trauma and invasion by microorganisms. The skin's health reflects the internal well-being of the body. The skin is also important for the perception of pain, heat, and cold and for the regulation of body temperature.

Differences in the Skin Between Children and Adults

The infant's epidermis is thinner than the adult's, and the blood vessels lie closer to the surface because there is a decreased amount of subcutaneous fat. Thus, the infant loses heat more readily through the skin's surface than the older child or adult does. The thinness of the infant's skin also allows substances to be absorbed through the skin more readily than they would be in an adult. Bacteria can gain access via the infant's and younger child's skin more readily than they can through the adult's skin. The infant's skin contains more water than in adults, and the epidermis is loosely bound to the dermis. This means that friction may easily cause separation of the layers, resulting in blistering or skin breakdown. The infant's skin is also less pigmented than that of the adult (in all races), placing the infant at increased risk of skin damage from ultraviolet radiation. Over time, the infant's skin toughens and becomes less hydrated and thus is less susceptible to microorganism invasion. The skin thickness and characteristics reach adult levels in the late teenage years (Starr, 2004).

Differences in Dark-Skinned Children

Children with dark skin tend to have more pronounced cutaneous reactions compared to children with lighter skin (Starr, 2004). Hypopigmentation or hyperpigmentation in the affected area following healing of a dermatologic condition is common in dark-skinned children. This change in pigmentation may be temporary (a few months following a superficial skin disorder) or permanent (following a more involved skin condition). Dark-skinned children tend to have more prominent papules, follicular responses, lichenification, and vesicular or bullous reactions than lighter-skinned children with the same disorder. Hypertrophic scarring and keloid formation (Fig. 45.1) occur more often in dark-skinned children.

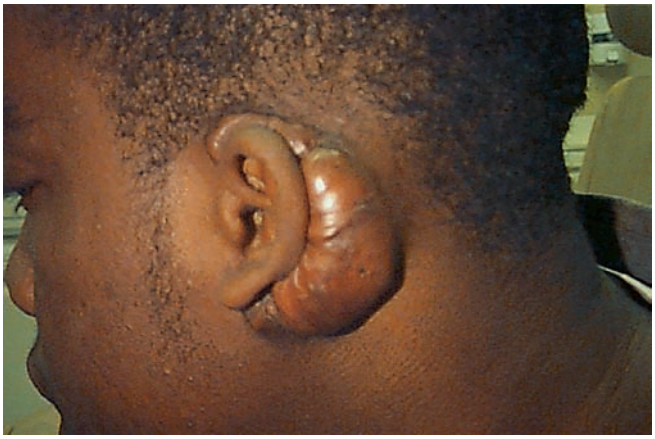

FIGURE 45.1 Keloid formation is more common in dark-skinned than light-skinned children.

Sebaceous and Sweat Glands

Sebaceous glands function immaturely at birth. The sebum secreted serves to lubricate the skin and hair. Sebum production increases in the preadolescent and adolescent years, which is why acne develops at that time. The infant's eccrine sweat glands are somewhat functional and will produce sweat as a response to emotional stimuli and heat. They become fully functional in the middle childhood years. Until that time, temperature regulation is less effective compared to older children and adults. The apocrine sweat glands are small and nonfunctional in the infant. They mature during puberty, at which time body odor develops in response to the fluid secreted by these glands.

Common Medical Treatments

A variety of medications as well as other medical treatments are used to treat integumentary disorders in children. Most of these treatments will require a physician's order when the child is in the hospital. The most common treatments and medications are listed in Common Medical Treatments 45.1 and Drug Guide 45.1. The nurse caring for the child with an integumentary disorder should be familiar with the procedures and medications, how they work, as well as common nursing implications related to their use.

COMMON MEDICAL TREATMENTS 45.1

Treatment	Explanation	Indications	Nursing Implications
Wet dressing	Dressing moistened with lukewarm water (sterile water may be required in certain cases)	In the presence of itching, crusting, or oozing—helps to remove crusts	May use Burow's, Domeboro, or saline solutions in certain cases. Provide atraumatic care by giving premedication before dressing change.
Sunscreen	Lotion, gel, or cream with a sun-protective factor (SPF)	All children over 6 months of age	Use a fragrance-free, para-aminobenzoic acid (PABA)–free preparation with an SPF of 15 or higher. Apply at least 30 minutes prior to sun exposure. Reapply at least every 2 hours while exposed (every 60 to 80 minutes while in the water). Sweat- and water-resistant preparations are available yet still require reapplication as noted above. Use daily in summer and in warm climates, even on overcast and cloudy days.
Bathing	Use of lukewarm water (with or without soap) to bathe	Itchy and irritating skin conditions	Recommend fragrance-free, dye-free soaps such as Dove, Aveeno, Basis, Lubriderm. Colloid (oatmeal baths) are especially helpful. Pat the child dry; do not rub the skin. Leave the child moist before applying medication, dressing, or moisturizer.

NURSING PROCESS OVERVIEW FOR THE CHILD WITH A INTEGUMENTARY DISORDER

Nursing management of the child with an integumentary disorder requires astute assessment skills, development of accurate nursing diagnoses and expected outcomes, implementation of appropriate interventions, and evaluation of the entire process. Many skin rashes may be associated with other, often serious, illnesses, so the nurse must use comprehensive and excellent assessment skills when evaluating rashes in children. Certain integumentary conditions are chronic and require ongoing care related to health maintenance, education, and psychosocial needs.

Assessment

Nursing assessment of the child with an integumentary disorder includes obtaining the health history and performing a physical examination. Assisting with or obtaining laboratory tests may also be necessary.

Remember Eva, the 1-year-old with the dry patches, itching, and trouble sleeping? What additional health history and physical examination assessment information should the nurse obtain?

Health History
