Abstract for research paper

Abstract

Opioids are a highly addictive drugs. They are addictive due to the fact that they chemically change the way the brain is wired. When opioid are used they give off a dopamine response. Dopamine is a type of neurotransmitter. Once the opioids are taken they send a signal to the brains that a person will feel high, very relaxed, or sleepy. Dopamine sends a signal to our brain on how to feel pleasure. Once a person become tolerant to the drug they will want more and more of the drug. This drug is prescribed for the relief of pain after surgery but once a person begins to use this drug just to feel normal it become addictive. Doctors and patients should be educated on the good and bad effect of painkillers.
